[svy] sdr exp\_list [, svy\_options sdr\_options eform\_option] : command

## **Syntax**

```
Description
 svy_options
if/in
 subpop([varname] [if])
                               identify a subpopulation
Reporting
 level(#)
                               set confidence level; default is level(95)
 noheader
                                suppress table header
 nolegend
                                suppress table legend
 noadjust
                               do not adjust model Wald statistic
 nocnsreport
                               do not display constraints
                               control column formats, row spacing, line width, display of omitted
 display_options
                                  variables and base and empty cells, and factor-variable labeling
                               display legend instead of statistics
 coeflegend
```

coeflegend is not shown in the dialog boxes for estimation commands.

sdr_options	Description		
Options			
$\underline{\mathtt{sa}}\mathtt{ving}(\mathit{filename}[,\dots])$	save results to <i>filename</i> ; save statistics in double precision; save results to <i>filename</i> every # replications		
mse	use MSE formula for variance		
Reporting			
<u>v</u> erbose	display the full table legend		
nodots	suppress replication dots		
<u>noi</u> sily	display any output from command		
<u>tr</u> ace	trace command		
<u>ti</u> tle( <i>text</i> )	use text as title for SDR results		
Advanced			
nodrop	do not drop observations		
reject( <i>exp</i> )	identify invalid results		
dof(#)	design degrees of freedom		

svy requires that the survey design variables be identified using svyset; see [SVY] svyset.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Warning: Using if or in restrictions will often not produce correct variance estimates for subpopulations. To compute estimates for subpopulations, use the subpop() option.

svy sdr requires that the successive difference replicate weights be identified using svyset.

```
exp_list contains
                      (name: elist)
                     elist
                     eexp
elist contains
                     newvarname = (exp)
                      (exp)
eexp is
                     specname
                      [eqno]specname
                     _b
specname is
                     _b[]
                      _se
                      _se[]
eqno is
                     ##
                     name
```

exp is a standard Stata expression; see [U] 13 Functions and expressions.

Distinguish between [], which are to be typed, and [], which indicate optional arguments.

#### Menu

Statistics > Survey data analysis > Resampling > Successive difference replications estimation

## **Description**

svy sdr performs successive difference replication (SDR) for complex survey data. Typing

. svy sdr exp\_list: command

executes command once for each replicate, using sampling weights that are adjusted according to the SDR methodology.

command defines the statistical command to be executed. Most Stata commands and user-written programs can be used with svy sdr as long as they follow standard Stata syntax, allow the if qualifier, and allow pweights and iweights; see [U] 11 Language syntax. The by prefix may not be part of *command*.

exp\_list specifies the statistics to be collected from the execution of command. exp\_list is required unless command has the svyb program property, in which case exp\_list defaults to \_b; see [P] program properties.

# **Options**

svy\_options; see [SVY] svy.

Options

saving(filename, suboptions) creates a Stata data file (.dta file) consisting of (for each statistic in *exp\_list*) a variable containing the replicates.

- double specifies that the results for each replication be stored as doubles, meaning 8-byte reals. By default, they are stored as floats, meaning 4-byte reals. This option may be used without the saving() option to compute the variance estimates by using double precision.
- every (#) specifies that results be written to disk every #th replication. every() should be specified in conjunction with saving() only when command takes a long time for each replication. This will allow recovery of partial results should some other software crash your computer. See [P] postfile.
- replace indicates that *filename* be overwritten if it exists. This option is not shown on the dialog box.
- mse specifies that svy sdr compute the variance by using deviations of the replicates from the observed value of the statistics based on the entire dataset. By default, svy sdr computes the variance by using deviations of the replicates from their mean.

Reporting

verbose requests that the full table legend be displayed.

- nodots suppresses display of the replication dots. By default, one dot character is printed for each successful replication. A red 'x' is printed if command returns with an error, and 'e' is printed if one of the values in *exp\_list* is missing.
- noisily requests that any output from command be displayed. This option implies the nodots option.
- trace causes a trace of the execution of command to be displayed. This option implies the noisily
- title(text) specifies a title to be displayed above the table of SDR results; the default title is "SDR results".

eform\_option; see [R] eform\_option. This option is ignored if exp\_list is not \_b.

```
Advanced
```

nodrop prevents observations outside e(sample) and the if and in qualifiers from being dropped before the data are resampled.

reject(exp) identifies an expression that indicates when results should be rejected. When exp is true, the resulting values are reset to missing values.

dof (#) specifies the design degrees of freedom, overriding the default calculation,  $df = N_{psu} - N_{strata}$ .

### Remarks and examples

#### stata.com

SDR was first introduced by Fay and Train (1995) as a method of variance estimation for annual demographic supplements to the Current Population Survey (CPS). In SDR, the model is fit multiple times, once for each of a set of adjusted sampling weights. The variance is estimated using the resulting replicated point estimates.

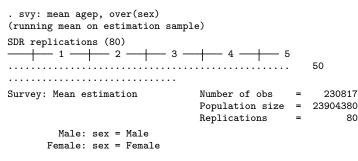

#### Example 1

The U.S. Census Bureau publishes public-use data from several of its surveys. This data can be downloaded from http://factfinder.census.gov. We downloaded the American Community Survey (ACS) Public Use Microdata Sample (PUMS) data collected in 2007. We extracted data for the state of Texas and kept the variables containing age, sex, and sampling weight for each person in the dataset. This sample dataset also contains 80 SDR weight variables.

This dataset was already svyset as

```
. svyset [pw=pwgtp], sdrweight(pwgtp1-pwgtp80) vce(sdr)
```

Here we estimate the average age of the males and of the females for our Texas subpopulation. The standard errors are estimated using SDR.

	Over	Mean	SDR Std. Err.	[95% Conf.	Interval]
agep					
٠.	Male	33.24486	.0470986	33.15255	33.33717
	Female	35.23908	.0386393	35.16335	35.31481

# Stored results

In addition to the results documented in [SVY] svy, svy sdr stores the following in e():

```
Scalars
    e(N_reps)
                   number of replications
    e(N_misreps) number of replications with missing values
                  number of standard expressions
    e(k_exp)
                  number of _b/_se expressions
    e(k_eexp)
    e(k_extra)
                  number of extra estimates added to _b
Macros
                  command name from command
    e(cmdname)
    e(cmd)
                  same as e(cmdname) or sdr
    e(vce)
    e(exp#)
                  #th expression
    e(sdrweight) sdrweight() variable list
Matrices
    e(b_sdr)
                  SDR means
    e(V)
                  SDR variance estimates
```

When exp\_list is \_b, svy sdr will also carry forward most of the results already in e() from command.

## Methods and formulas

See [SVY] variance estimation for details regarding SDR variance estimation.
