12.1 Data and datasets

Data form a rectangular table of numeric and string values in which each row is an observation on all the variables and each column contains the observations on one variable. Variables are designated by variable names. Observations are numbered sequentially from 1 to _N_. The following example of data contains the first five odd and first five even positive integers, along with a string variable:

<table>
<thead>
<tr>
<th>odd</th>
<th>even</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>Bill</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>Mary</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>Pat</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>Roger</td>
</tr>
<tr>
<td>9</td>
<td>10</td>
<td>Sean</td>
</tr>
</tbody>
</table>
The observations are numbered 1 to 5, and the variables are named odd, even, and name. Observations are referred to by number, and variables by name.

A dataset is data plus labelings, formats, notes, and characteristics.

All aspects of data and datasets are defined here. Long (2009) offers a long-time Stata user’s hard-won advice on how to manage data in Stata to promote accurate, replicable research. Mitchell (2010) provides many examples on data management in Stata.

12.2 Numbers

A number may contain a sign, an integer part, a decimal point, a fraction part, an e or E, and a signed integer exponent. Numbers may not contain commas; for example, the number 1,024 must be typed as 1024 (or 1024. or 1024.0). The following are examples of valid numbers:

```
5
-5
5.2
.5
5.2e+2
5.2e-2
```

Technical note

Stata also allows numbers to be represented in a hexadecimal/binary format, defined as

```
[+-] 0.0 [zeros] {X|x}^-3ff
```

or

```
[+-] 1. ⟨hexdigit⟩ [ ⟨hexdigits⟩ {x|x} {+-} ⟨hexdigit⟩ [ ⟨hexdigits⟩ ]
```

The lead digit is always 0 or 1; it is 0 only when the number being expressed is zero. A maximum of 13 digits to the right of the hexadecimal point are allowed. The power ranges from -3ff to +3ff. The number is expressed in hexadecimal (base 16) digits; the number $aX+b$ means $a \times 2^b$. For instance, $1.0X+3$ is $2^3$ or 8. $1.8X+3$ is 12 because $1.8_{16}$ is $1 + 8/16 = 1.5$ in decimal and the number is thus $1.5 \times 2^3 = 1.5 \times 8 = 12$.

Stata can also display numbers using this format; see [U] 12.5.1 Numeric formats. For example,

```
. di 1.81x+2
6.015625
. di %21x 6.015625
+1.810000000000000X+002
```

This hexadecimal format is of special interest to numerical analysts.

12.2.1 Missing values

A number may also take on the special value missing, denoted by a period (.). You specify a missing value anywhere that you may specify a number. Missing values differ from ordinary numbers in one respect: any arithmetic operation on a missing value yields a missing value.
In fact, there are 27 missing values in Stata: ‘.’, the one just discussed, as well as .a, .b, . . . , and .z, which are known as extended missing values. The missing value ‘.’ is known as the default or system missing value. In any case, some people use extended missing values to indicate why a certain value is unknown—the question was not asked, the person refused to answer, etc. Other people have no use for extended missing values and just use ‘.’.

Stata’s default or system missing value will be returned when you perform an arithmetic operation on missing values or when the arithmetic operation is not defined, such as division by zero, or the logarithm of a nonpositive number.

```
. display 2/0
. list
   +----+----+
   | a   |    |
   +----+----+
   1.   .b
   2.   .
   3.   .a
   4. 3
   5. 6
   +----+----+

. generate x = a + 1
   (3 missing values generated)
. list
   +----+----+
   | a   | x   |
   +----+----+
   1.   .b
   2.   . .
   3.   .a
   4. 3 4
   5. 6 7
   +----+----+
```

Numeric missing values are represented by “large positive values”. The ordering is

all numbers < . < .a < .b < . . . < .z

Thus the expression

\[
\text{age} > 60
\]

is true if variable \text{age} is greater than 60 or is missing. Similarly,

\[
\text{gender} \neq 0
\]

is true if \text{gender} is not zero or is missing.

The way to exclude missing values is to ask whether the value is less than ‘.’, and the way to detect missing values is to ask whether the value is greater than or equal to ‘.’. For instance,

```
. list if age>60 & age<.
. generate agegt60 = 0 if age<=60
. replace agegt60 = 1 if age>60 & age<.
. generate agegt60 = (age>60) if age<.
```
### Technical note

Before Stata 8, Stata only had one representation for missing values, the period (.).

To ensure that old programs and do-files continue to work properly, when version is set less than 8, all missing values are treated as being the same. Thus . == .a == .b == .z, and so ‘exp==.’ and ‘exp!=.’ work just as they previously did.

### Example 1

We have data on the income of husbands and wives recorded in the variables hincome and wincome, respectively. Typing the list command, we see that your data contain:

```
. use http://www.stata-press.com/data/r13/gxmpl3
. list
```

<table>
<thead>
<tr>
<th>hincome</th>
<th>wincome</th>
</tr>
</thead>
<tbody>
<tr>
<td>32000</td>
<td>0</td>
</tr>
<tr>
<td>35000</td>
<td>34000</td>
</tr>
<tr>
<td>47000</td>
<td>.b</td>
</tr>
<tr>
<td>.z</td>
<td>50000</td>
</tr>
<tr>
<td>.a</td>
<td>.</td>
</tr>
</tbody>
</table>

The values of wincome in the third and fifth observations are missing, as distinct from the value of wincome in the first observation, which is known to be zero.

If we use the generate command to create a new variable, income, that is equal to the sum of hincome and wincome, three missing values would be produced:

```
. generate income = hincome + wincome
(3 missing values generated)
. list
```

<table>
<thead>
<tr>
<th>hincome</th>
<th>wincome</th>
<th>income</th>
</tr>
</thead>
<tbody>
<tr>
<td>32000</td>
<td>0</td>
<td>32000</td>
</tr>
<tr>
<td>35000</td>
<td>34000</td>
<td>69000</td>
</tr>
<tr>
<td>47000</td>
<td>.b</td>
<td>.</td>
</tr>
<tr>
<td>.z</td>
<td>50000</td>
<td>.</td>
</tr>
<tr>
<td>.a</td>
<td>.</td>
<td>.</td>
</tr>
</tbody>
</table>

generate produced a warning message that 3 missing values were created, and when we list the data, we see that 47,000 plus missing yields missing.
Technical note

Stata stores numeric missing values as the largest 27 numbers allowed by the particular storage type; see \[U\] 12.2.2 Numeric storage types. There are two important implications. First, if you sort on a variable that has missing values, the missing values will be placed last, and the sort order of any missing values will follow the rule regarding the properties of missing values stated above.

```
. sort wincome
. list wincome

<table>
<thead>
<tr>
<th>wincome</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. 0</td>
</tr>
<tr>
<td>2. 34000</td>
</tr>
<tr>
<td>3. 50000</td>
</tr>
<tr>
<td>4. .</td>
</tr>
<tr>
<td>5. .b</td>
</tr>
</tbody>
</table>
```

The second implication concerns relational operators and missing values. Do not forget that a missing value will be larger than any numeric value.

```
. list if wincome > 40000

<table>
<thead>
<tr>
<th>hincome</th>
<th>wincome</th>
<th>income</th>
</tr>
</thead>
<tbody>
<tr>
<td>3. .z</td>
<td>50000</td>
<td>.</td>
</tr>
<tr>
<td>4. .a</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>5. 47000</td>
<td>.b</td>
<td>.</td>
</tr>
</tbody>
</table>
```

Observations 4 and 5 are listed because ‘.’ and ‘.b’ are both missing and thus are greater than 40,000. Relational operators are discussed in detail in \[U\] 13.2.3 Relational operators.

Example 2

In producing statistical output, Stata ignores observations with missing values. Continuing with the example above, if we request summary statistics on hincome and wincome by using the summarize command, we obtain

```
. summarize hincome wincome

Variable | Obs | Mean | Std. Dev. | Min | Max
---------|-----|------|-----------|-----|-----
hincome  | 3   | 38000| 7937.254  | 32000| 47000|
wincome  | 3   | 28000| 25534.29  | 0   | 50000|
```

Some commands discard the entire observation (known as casewise deletion) if one of the variables in the observation is missing. If we use the correlate command to obtain the correlation between hincome and wincome, for instance, we obtain

```
. correlate hincome wincome
(obs=2)

<table>
<thead>
<tr>
<th>hincome</th>
<th>wincome</th>
</tr>
</thead>
<tbody>
<tr>
<td>hincome</td>
<td>1.0000</td>
</tr>
<tr>
<td>wincome</td>
<td>1.0000</td>
</tr>
</tbody>
</table>
```

The correlation coefficient is calculated over two observations.
12.2.2 Numeric storage types

Numbers can be stored in one of five variable types: byte, int, long, float (the default), or double. bytes are, naturally, stored in 1 byte. ints are stored in 2 bytes, longs and floats in 4 bytes, and doubles in 8 bytes. The table below shows the minimum and maximum values for each storage type.

<table>
<thead>
<tr>
<th>Storage type</th>
<th>Minimum</th>
<th>Maximum</th>
<th>Closest to 0 without being 0</th>
<th>Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>byte</td>
<td>−127</td>
<td>100</td>
<td>±1</td>
<td>1</td>
</tr>
<tr>
<td>int</td>
<td>−32,767</td>
<td>32,740</td>
<td>±1</td>
<td>2</td>
</tr>
<tr>
<td>long</td>
<td>−2,147,483,647</td>
<td>2,147,483,620</td>
<td>±1</td>
<td>4</td>
</tr>
<tr>
<td>float</td>
<td>$-1.70141173319 \times 10^{38}$</td>
<td>$1.70141173319 \times 10^{38}$</td>
<td>$\pm 10^{-38}$</td>
<td>4</td>
</tr>
<tr>
<td>double</td>
<td>$-8.9884656743 \times 10^{307}$</td>
<td>$+8.9884656743 \times 10^{307}$</td>
<td>$\pm 10^{-323}$</td>
<td>8</td>
</tr>
</tbody>
</table>

Do not confuse the term integer, which is a characteristic of a number, with int, which is a storage type. For instance, the number 5 is an integer, no matter how it is stored; thus, if you read that an argument must be an integer, that does not mean that it must be stored as an int.

12.3 Dates and times

Stata has nine date, time, and date-and-time numeric encodings known collectively as %t variables or values. They are

- %tc calendar date and time, adjusted for leap seconds
- %tc calendar date and time, ignoring leap seconds
- %td calendar date
- %tw week
- %tm calendar month
- %tq financial quarter
- %th financial half-year
- %ty calendar year
- %tb business calendars

All except %ty and %tb are based on 0 = beginning of January 1960. %tc and %tc record the number of milliseconds since then. %td records the number of days. The others record the numbers of weeks, months, quarters, or half-years. %ty simply records the year, and %tb records a user-defined business calendar format.

For a full discussion of working with dates and times, see [U] 24 Working with dates and times.
12.4 Strings

This section describes the treatment of strings by Stata. The section is divided into the following subsections:

- [U] 12.4.1 Overview
- [U] 12.4.2 Strings containing identifying data
- [U] 12.4.3 Strings containing categorical data
- [U] 12.4.4 Strings containing numeric data
- [U] 12.4.5 String literals
- [U] 12.4.6 str1–str2045 and str
- [U] 12.4.7 strL
- [U] 12.4.8 strL variables and duplicated values
- [U] 12.4.9 strL variables and binary strings
- [U] 12.4.10 strL variables and files
- [U] 12.4.11 String display formats
- [U] 12.4.12 How to see the full contents of a strL or a str# variable
- [U] 12.4.13 Notes for programmers

12.4.1 Overview

A string is a sequence of characters:

Samuel Smith
California
U.K.

Usually—but not always—strings are enclosed in double quotes:

"Samuel Smith"
"California"
"U.K."

Strings typed in quotes are called string literals.

Strings can be stored in Stata datasets in string variables.

```
. use http://www.stata-press.com/data/r13/auto, clear
   (1978 Automobile Data)
. describe make

    storage  display  value
  variable name type format label  variable label
           make    str18   %-18s         Make and Model

```

The string-variable storage types are str1, str2, ..., str2045, and strL.

Variable `make` is a str18 variable. It can contain strings of up to 18 characters long. The strings are not all 18-characters long:

```
. list make in 1/2

<table>
<thead>
<tr>
<th>make</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. AMC Concord</td>
</tr>
<tr>
<td>2. AMC Pacer</td>
</tr>
</tbody>
</table>
```
str18 means that the variable cannot hold a string longer than 18 characters, and even that is an unimportant detail, because Stata automatically promotes str# variables to be longer when required:

```
. replace make = "Mercedes Benz Gullwing" in 1  
  make was str18 now str22  
  (1 real change made)
```

Stata provides a suite of string functions, such as strlen(), substr():

```
. generate len = strlen(make)  
. generate str first5 = substr(make, 1,5)  
. list make len first5 in 1/2
```

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>make</td>
<td>len</td>
<td>first5</td>
</tr>
<tr>
<td>-------</td>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td>1.</td>
<td>Mercedes Benz Gullwing</td>
<td>22</td>
</tr>
<tr>
<td>2.</td>
<td>AMC Pacer</td>
<td>9</td>
</tr>
</tbody>
</table>

Many Stata commands can use string variables:

```
. generate str brand = word(make, 1)  
. tabulate brand
```

<table>
<thead>
<tr>
<th>brand</th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMC</td>
<td>2</td>
<td></td>
<td>2.70</td>
</tr>
<tr>

</tr>
</tbody>
</table>

| Total  | 74    | 100.00 |

### 12.4.2 Strings containing identifying data

String variables often contain identifying information, such as the patient’s name or the name of the city or state. Such strings are typically listed but are not used directly in statistical analysis, although the data might be sorted on the string or datasets might be merged on the basis of one or more string variables.
12.4.3 Strings containing categorical data

Strings sometimes contain information to be used directly in analysis, such as the patient’s sex, which might be coded “male” or “female”. Stata shows a decided preference for such information to be numerically encoded and stored in numeric variables. Stata’s statistical routines treat string variables as if every observation records a numeric missing value. Stata provides two commands for converting string variables into numeric codes and back again: `encode` and `decode`; see [U] 23.2 Categorical string variables and [U] 11.4.3 Factor variables.

12.4.4 Strings containing numeric data

If a string variable contains the character representation of a number, say, `myvar` contains “1”, “1.2”, and “—5.2”, you can convert the string into a numeric value by using the `real()` function or the `destring` command. For example,

```
generate newvar = real(myvar)
```

If you want to convert a numeric variable to its string representation, you can use the `string()` function or the `tostring` command. For example,

```
generate as_str = string(numvar)
```

See [D] functions and [D] destring.

12.4.5 String literals

A string literal is a sequence of printable characters enclosed in quotes. The quotes are not considered part of the string; they merely serve to delimit the beginning and end of the string. The following are examples of string literals:

```
"Hello, world"
"String"
"string"
" string"
"string 
"
"x/y+3"
"1.2"
```

All the strings above are distinct. Capitalization matters. Leading and trailing spaces matter. Also note that "1.2" is a string and not a number because it is enclosed in quotes.

There is never a circumstance in which a string cannot be delimited with quotes, but there are instances where strings do not have to be delimited by quotes, such as when inputting data. In those cases, nondelimited strings are stripped of their leading and trailing blanks. Delimited strings are always accepted as is.

The list above could also be written as

```
'"Hello, world"
'"String"
'"string"
'" string"
'"string 
"
'"x/y+3"
'"1.2"
```
"" and ") are called compound double quotes.

Use of compound double quotes is how you solve the problem of typing strings that themselves contain double quotes:

""Bob said, "Wow!" and promptly fainted.""

Strings in compound quotes can themselves contain compound quotes:

""The compound quotes characters are "" and "),

12.4.6 str1–str2045 and str

str is something generate understands. We will get to that.

str1–str2045 are known as Stata’s fixed-length string storage types.

They are called that because, in your dataset, if a variable is stored as a str#, then each observation requires # bytes to store the contents of the variable. You obviously do not want # to be longer than necessary. Stata’s compress command will shorten str# strings that are unnecessarily long:

```
. use http://www.stata-press.com/data/r13/auto, clear
(1978 Automobile Data)
. compress
mpg was int now byte
rep78 was int now byte
trunk was int now byte
turn was int now byte
make was str18 now str17
(370 bytes saved)
```

In [U] 12.4.1 Overview, you saw us use str with generate:

```
. generate str brand = word(make, 1)
```

str is something generate understands and tells generate to create a str# variable of the minimum required length. Although you cannot tell from the output, generate created variable brand as a str7.

Stata commands automatically promote str# storage types when necessary:

```
. replace make = "Mercedes Benz Gullwing" in 1
make was str17 now str22
(1 real change made)
```

In fact, if the string to be stored is longer than 2,045 characters, generate and replace will even promote to strL. strLs are the subject of the next section.

12.4.7 strL

strL variables can be 0 to 2-billion characters long.

The “L” stands for long, and strL is often pronounced sturl.

strL variables are not required to be longer than 2,045 characters.

str# variables can store strings of up to 2,045 characters, so strL and str# overlap. This overlap is comparable to the overlap of the numeric types int and float. Any number that can be stored as an int can be stored as a float, and similarly, any string that can be stored as a str# can be stored as a strL. The reverse is not true. In addition, strL variables can hold binary strings, whereas str# variables can only hold ASCII strings. Thus the analogy between str#/strL and int/float is exact. There will be occasions when you will want to use strL variables in preference to str# variables, just as there are occasions when you will want to use float variables in preference to int variables.
strL variables work just like str# variables. Below we repeat what we did in [U] 12.4.1 Overview using a strL variable:

```stata
. use http://www.stata-press.com/data/r13/auto, clear
(1978 Automobile Data)
. generate strL mymake = make
. describe mymake
storage  display  value
--- variables ---(example)---
mymake     strL     %9s
```

We can replace strL values just as we can replace str# values:

```stata
. replace mymake = "Mercedes Benz Gullwing" in 1
   (1 real change made)
```

We can use string functions with strL variables just as we can with str# variables:

```stata
. generate len = strlen(mymake)
. generate strL first5 = substr(mymake, 1, 5)
```

We can even make tabulations:

```stata
. generate strL brand = word(mymake, 1)
. tabulate brand

<table>
<thead>
<tr>
<th>brand</th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMC</td>
<td>2</td>
<td>2.70</td>
<td>2.70</td>
</tr>
<tr>
<td>Audi</td>
<td>2</td>
<td>2.70</td>
<td>5.41</td>
</tr>
<tr>
<td>BMW</td>
<td>1</td>
<td>1.35</td>
<td>6.76</td>
</tr>
<tr>
<td>(output omitted)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Volvo</td>
<td>1</td>
<td>1.35</td>
<td>100.00</td>
</tr>
<tr>
<td>Total</td>
<td>74</td>
<td>100.00</td>
<td></td>
</tr>
</tbody>
</table>
```

The only limitations are the following:

1. You cannot use strL variables as the matching (key) variables in a match merge of two datasets.
2. They cannot be used with fillin.

strL variables are stored differently from str# variables. str# variables require # bytes per observation. strL variables require the actual number of bytes per string per observation, which means strLs require even less memory than str# when the value being stored is less than # characters long. Most strLs, however, have an 80-byte overhead per value stored (the exception is strLs containing empty strings), in which case the overhead is 8 bytes.
Whether `strL` or `str#` requires less memory for storing the same string values depends on the string values themselves. `compress` can figure that out:

```
. compress
  mpg was int now byte       rep78 was int now byte
  trunk was int now byte     turn was int now byte
  len was float now byte     make was str18 now str17
  mymake was strL now str22  first5 was strL now str5
  trunk was int now byte     brand was strL now str8
(8,244 bytes saved)
```

`compress` decided to demote all of our `strL` variables to `str#` because that would save memory. `compress`, however, never promotes a `str#` variable to a `strL` even if that would save memory. It does not because, as we mentioned, there are a few things you can do with `str#` variables that you cannot do with `strL` variables.

You can use `recast` to promote `str#` to `strL`:

```
. * variable make is currently str17
. recast strL make
. describe make

<table>
<thead>
<tr>
<th>variable name</th>
<th>type</th>
<th>format</th>
<th>label</th>
</tr>
</thead>
<tbody>
<tr>
<td>make</td>
<td>strL</td>
<td>%-9s</td>
<td>Make and Model</td>
</tr>
</tbody>
</table>

. compress make
  make was strL now str17
(3,831 bytes saved)
```

### 12.4.8 `strL` variables and duplicated values

You would never know it, but when `strL` variables have the same values across observations, Stata stores only one copy of each value. That is called coalescing and it saves memory.

Stata mostly coalesces `strL` variables automatically as they are created, but sometimes duplicate values escape its attention. When you type `compress`, however, Stata looks for coalescing opportunities. You might see

```
. compress x
  x is strL now coalesced
(11,301,687 bytes saved)
```

We recommend that you type `compress` occasionally when `strL` variables are present.

### 12.4.9 `strL` variables and binary strings

`strL`s can hold binary strings. A binary string is, technically speaking, any string that contains binary 0. Here is a silly example:
. use http://www.stata-press.com/data/r13/auto, clear
(1978 Automobile Data)
. replace make = "a" + char(0) + "b" in 1
make was str18 now strL
(1 real change made)
. list make in 1

<table>
<thead>
<tr>
<th>make</th>
</tr>
</thead>
<tbody>
<tr>
<td>a\0b</td>
</tr>
</tbody>
</table>

list displays binary zeros as \0.

If we did this same experiment with a str# variable and include the nopromote option to prevent promotion, we would see something different:

. use http://www.stata-press.com/data/r13/auto, clear
(1978 Automobile Data)
. replace make = "a" + char(0) + "b" in 1, nopromote
(1 real change made)
. list make in 1

<table>
<thead>
<tr>
<th>make</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
</tr>
</tbody>
</table>

For str# strings, binary 0 indicates the end of the string, and thus the variable really does contain “a” in the first observation.

str# variables cannot contain binary 0; strL variables can.

compress knows this. If we typed compress in the first example, we would discover that compress would not demote make to be a str#. It would not because one of the values could not be stored in a str# variable. This is no different from compress not demoting a float variable to an int because one of the values is 1.5.

12.4.10 strL variables and files

One of the neat things you can do with strLs is use them to hold the contents of files. We have data on 10 patients. Some of the data have been coded from doctor notes, and those notes are stored in notes_2217.xyz, notes_2221.xyz, notes_2222.xyz, and so on. We could do the following:

. generate strL notes = fileread("notes_2217.xyz") in 1
. replace notes = fileread("notes_2221.xyz") in 2
. replace notes = fileread("notes_2222.xyz") in 3
. ....

It would be even easier for us to type

. generate str fname = "notes_" + string(patid) + ".xyz"
. generate strL notes = fileread(fname)

The original files can be re-created from the copies stored in Stata. To re-create all the files, we could type

. generate len = filewrite(fname, notes)
If we want to know whether the phrase “Diabetes Mellitus Type 1” appears in the notes and whether doctors recorded the disease as T1DM, we can type:

```
    . generate t2dm = (strpos("notes", "T1DM")) != 0
```

Of course, that depends on the `notes_*_.xyz` files being either ASCII or ASCII-like enough so that the T1DM would show up as “T1DM”.

Note that `strpos()` and all of Stata 13’s string functions work with long strings and with binary strings.

### 12.4.11 String display formats

The format for strings is `%[−]#s`, such as `%18s` and `%−18s`. # may be up to 2,045. # indicates the width of the field. %#s specifies that the string be displayed right-aligned in the field, and %−#s specifies that the string is displayed left-aligned.

Stata sets good default formats for `str#` variables. The default format is %#s, so if a variable is `str18`, its default format is %18s.

Stata sets poor default formats for `strL` variables. Stata uses %9s in all cases. Because `strL` variables can be so long, there is no good choice for the format; the question is merely how much of the string you want to see.

When the format is too short for the length of the string, whether the string is `str#` or `strL`, Stata usually displays # – 2 characters of the string and adds two dots at the end. We say “usually” because a few commands are able to do something better than that.

### 12.4.12 How to see the full contents of a `strL` or a `str#` variable

By default, the `list` command shows only the first part of long strings, followed by two dots. How much `list` shows is determined by the width of your Results window.

`list` will show the first 2,045 characters of long strings, whether stored as `strLs` or `str#s`, if you add the `notrim` option:

```
    . list, notrim
    (output omitted)
    . list mystr, notrim
    (output omitted)
    . list mystr in 5, notrim
    (output omitted)
```

Another way to display long strings is to use the `display` command. With `display`, you can see the entire contents. To display the fifth observation of the variable `mystr`, you type:

```
    . display _asis mystr[5]
    (output omitted)
```

That one command can produce a lot of output if the string is long, even hundreds of thousands of pages! Remember that you can press `Break` to stop the listing.

If you wanted to see the first 5,000 characters of the string, type:

```
    . display _asis subst(mystr[5], 1, 5000)
```

If you really wanted a full listing of a long string, you will want to `set more off` first:

```
    . set more off
    . display _asis mystr[5]
    (output omitted)
```
Very rarely, a string variable might contain SMCL output. SMCL is Stata’s text markup language. A variable might contain SMCL if you used `fileread()` to read a Stata log file into it. In that case, you can see the text correctly formatted by typing

```
. display as txt mystr[1]
(output omitted)
```

To learn more about other features of `display`, see [R] `display`.

### 12.4.13 Notes for programmers

The maximum length of macros is shorter than that of `strLs`. This means

1. you can use macros in string expressions without fear that results will be truncated.
2. you can enclose expanded macros in quotes—`"macname"`—to form string literals without fear of truncation.
3. macros cannot hold binary strings. If you are working with binary strings, use string scalars, which are also implemented as `strLs`. See [P] `scalar`.
4. you should not assume that the result of a string expression will fit into a macro. If you are sure it will, go ahead and store the result into a macro. If you are not sure, use a string scalar, which can hold a `strL`.
5. you should not assume that the contents of a `strL` variable will fit into a macro. Use string scalars.
6. in programming, use string scalars just as you would use numeric scalars.

```
program ...
    version 13
    ...
    tempname mystr
    ...
    scalar `mystr' = ...
    ...
    generate ... = ...`mystr'... 
    ...
end
```

`mystr` in the above code is a macro containing a temporary name. Thus `mystr'` is a reference, not an expansion, of the contents of the string scalar.

### 12.5 Formats: Controlling how data are displayed

Formats describe how a number or string is to be presented. For instance, how is the number 325.24 to be presented? As 325.2, or 325.24, or 325.240, or 3.2524e+02, or 3.25e+02, or some other way? The `display format` tells Stata exactly how to present such data. You do not have to specify display formats because Stata always makes reasonable assumptions about how to display a variable, but you always have the option.
12.5.1 Numeric formats

A Stata numeric format is formed by

<table>
<thead>
<tr>
<th>first type</th>
<th>%</th>
<th>to indicate the start of the format</th>
</tr>
</thead>
<tbody>
<tr>
<td>then optionally type</td>
<td>-</td>
<td>if you want the result left-aligned</td>
</tr>
<tr>
<td>then optionally type</td>
<td>0</td>
<td>if you want to retain leading zeros (1)</td>
</tr>
<tr>
<td>then type</td>
<td>a number $w$</td>
<td>stating the width of the result</td>
</tr>
<tr>
<td>then type</td>
<td>.</td>
<td></td>
</tr>
<tr>
<td>then type</td>
<td>a number $d$</td>
<td>stating the number of digits to follow the decimal point</td>
</tr>
<tr>
<td>then type</td>
<td>either</td>
<td></td>
</tr>
<tr>
<td></td>
<td>e</td>
<td>for scientific notation, e.g., 1.00e+03</td>
</tr>
<tr>
<td></td>
<td>or</td>
<td>f</td>
</tr>
<tr>
<td></td>
<td>or</td>
<td>g</td>
</tr>
<tr>
<td>then optionally type</td>
<td>c</td>
<td>to indicate comma format (not allowed with e)</td>
</tr>
</tbody>
</table>

(1) Specifying 0 to mean “include leading zeros” will be honored only with the $f$ format.

For example,

\%
\%9.0g  general format, 9 columns wide
\%
\%9.0gc general format, 9 columns wide, with commas
\%
\%9.2f  fixed format, 9 columns wide, 2 decimal places
\%
\%9.2fc fixed format, 9 columns wide, 2 decimal places, with commas
\%
\%9.2e  exponential format, 9 columns wide

Stata has three numeric format types: $e$, $f$, and $g$. The formats are denoted by a leading percent sign (%) followed by the string $w.d$, where $w$ and $d$ stand for two integers. The first integer, $w$, specifies the width of the format. The second integer $d$ specifies the number of digits that are to follow the decimal point. $d$ must be less than $w$. Finally, a character denotes the format type ($e$, $f$, or $g$), and to that may optionally be appended a $c$ indicating that commas are to be included in the result ($c$ is not allowed with $e$).

By default, every numeric variable is given a \%$w$.0g format, where $w$ is large enough to display the largest number of the variable’s type. The \%$w$.0g format is a set of formatting rules that present the values in as readable a fashion as possible without sacrificing precision. The $g$ format changes the number of decimal places displayed whenever it improves the readability of the current value.
The default formats for each of the numeric variable types are

<table>
<thead>
<tr>
<th>Type</th>
<th>Default Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>byte</td>
<td>%8.0g</td>
</tr>
<tr>
<td>int</td>
<td>%8.0g</td>
</tr>
<tr>
<td>long</td>
<td>%12.0g</td>
</tr>
<tr>
<td>float</td>
<td>%9.0g</td>
</tr>
<tr>
<td>double</td>
<td>%10.0g</td>
</tr>
</tbody>
</table>

You can change the format of a variable by using the `format varname %fmt` command.

In addition to `%w.0g`, allowed is `%w.0gc` to display numbers with commas. “One thousand” is displayed as 1000 in `%9.0g` format and as 1,000 in `%9.0gc` format.

In addition to using `%w.0g` and `%w.0gc`, you can use `%w.dg` and `%w.dgc`, \( d > 0 \). For example, `%9.4g` and `%9.4gc`. The 4 means to display approximately four significant digits. For instance, the number 3.14159265 in `%9.4g` format is displayed as 3.142, 31.4159265 as 31.42, 314.159265 as 314.2, and 3141.59265 as 3142. The format is not exactly a significant-digit format because 31415.9265 is displayed as 31416, not as 3.142e+04.

Under the `f` format, values are always displayed with the same number of decimal places, even if this results in a loss in the displayed precision. Thus the `f` format is similar to the C `f` format. Stata’s `f` format is also similar to the Fortran `F` format, but, unlike the Fortran `F` format, it switches to `g` whenever a number is too large to be displayed in the specified `f` format.

In addition to `%w.df`, the format `%w.dfc` can display numbers with commas.

The `e` format is similar to the C `e` and the Fortran `E` format. Every value is displayed as a leading digit (with a minus sign, if necessary), followed by a decimal point, the specified number of digits, the letter `e`, a plus sign or a minus sign, and the power of 10 (modified by the preceding sign) that multiplies the displayed value. When the `e` format is specified, the width must exceed the number of digits that follow the decimal point by at least seven to accommodate the leading sign and digit, the decimal point, the `e`, and the signed power of 10.

### Example 3

Below we have a 5-observation dataset with three variables: `e_fmt`, `f_fmt`, and `g_fmt`. All three variables have the same values stored in them; only the display format varies. `describe` shows the display format to the right of the variable type:

```
. use http://www.stata-press.com/data/r13/format, clear
. describe
Contains data from http://www.stata-press.com/data/r13/format.dta
    obs:      5                         12 Mar 2013 15:18
    vars:     3
    size:    60

+---------------------------------+---------------------+----------+---------------------+----------+---------------------+---------------------------------+
  variable name | type | display format | value label | variable name | type | display format | value label | variable label |
+---------------------------------+---------------------+----------+---------------------+----------+---------------------+---------------------------------+
  e_fmt           | float | %9.2e           |           | f_fmt           | float | %10.2f           |           |               |
  f_fmt           | float | %10.2f          |           | g_fmt           | float | %9.0g           |           |               |
+---------------------------------+---------------------+----------+---------------------+----------+---------------------+---------------------------------+
```

Sorted by:

The formats for each of these variables were set by typing

```
. format e_fmt %9.2e
. format f_fmt %10.2f
```
It was not necessary to set the format for the \texttt{g\_fmt} variable because Stata automatically assigned it the \texttt{\%9.0g} format. Nevertheless, we could have typed \texttt{format g\_fmt \%9.0g} if we wished. Listing the data results in

\begin{verbatim}
  . list

<table>
<thead>
<tr>
<th></th>
<th>e_fmt</th>
<th>f_fmt</th>
<th>g_fmt</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2.80e+00</td>
<td>2.80</td>
<td>2.801785</td>
</tr>
<tr>
<td>2</td>
<td>3.96e+06</td>
<td>3962322.50</td>
<td>3962323</td>
</tr>
<tr>
<td>3</td>
<td>4.85e+00</td>
<td>4.85</td>
<td>4.852834</td>
</tr>
<tr>
<td>4</td>
<td>-5.60e-06</td>
<td>-0.00</td>
<td>-5.60e-06</td>
</tr>
<tr>
<td>5</td>
<td>6.26e+00</td>
<td>6.26</td>
<td>6.264982</td>
</tr>
</tbody>
</table>
\end{verbatim}

Technical note

The discussion above is incomplete. There is one other format available that will be of interest to numerical analysts. The \texttt{\%21x} format displays base 10 numbers in a hexadecimal (base 16) format. The number is expressed in hexadecimal (base 16) digits; the number \texttt{aX+b} means \( a \times 2^b \). For example,

\begin{verbatim}
  . display \%21x 1234.75
 +1.34b0000000000X+00a
\end{verbatim}

Thus the base 10 number 1,234.75 has a base 16 representation of \texttt{1.34bX+0a}, meaning

\[
\left( 1 + 3 \cdot 16^{-1} + 4 \cdot 16^{-2} + 11 \cdot 16^{-3} \right) \times 2^{10}
\]

Remember, the hexadecimal–decimal equivalents are

<table>
<thead>
<tr>
<th>hexadecimal</th>
<th>decimal</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>5</td>
</tr>
<tr>
<td>6</td>
<td>6</td>
</tr>
<tr>
<td>7</td>
<td>7</td>
</tr>
<tr>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>9</td>
<td>9</td>
</tr>
<tr>
<td>a</td>
<td>10</td>
</tr>
<tr>
<td>b</td>
<td>11</td>
</tr>
<tr>
<td>c</td>
<td>12</td>
</tr>
<tr>
<td>d</td>
<td>13</td>
</tr>
<tr>
<td>e</td>
<td>14</td>
</tr>
<tr>
<td>f</td>
<td>15</td>
</tr>
</tbody>
</table>

See [U] 12.2 Numbers.
12.5.2 European numeric formats

The three numeric formats e, f, and g will use ‘,’ to indicate the decimal symbol if you specify their width and depth as \(w, d\) rather than \(w . d\). For instance, the format \%9,0g will display what Stata would usually display as 1.5 as 1,5.

If you use the European specification with fc or gc, the “comma” will be presented as a period. For instance, \%9,0gc will display what Stata would usually display as 1,000.5 as 1.000,5.

If this way of presenting numbers appeals to you, consider using Stata’s set dp comma command. set dp comma tells Stata to interpret nearly all \%w.d{g|f|e} formats as \%w,\!d\{g|f|e\} formats. Most of Stata is written using a period to represent the decimal symbol, and that means that, even if you set the appropriate \%w,d\{g|f|e\} format for your data, it will affect only displays of the data. For instance, if you type summarize to obtain summary statistics or regress to obtain regression results, the decimal will still be shown as a period.

set dp comma changes that and affects all of Stata. With set dp comma, it does not matter whether your data are formatted \%w.d\{g|f|e\} or \%w,\!d\{g|f|e\}. All results will be displayed using a comma as the decimal character:

```
use http://www.stata-press.com/data/r13/auto
(1978 Automobile Data)
set dp comma
summarize mpg weight foreign
Variable | Obs Mean Std. Dev. Min Max
---------|--------+---------+---------+---------+---------+
mpg | 74 21,2973 5,785503 12 41
weight | 74 3019,459 777,1936 1760 4840
foreign | 74 ,2972973 ,4601885 0 1
```

```
regress mpg weight foreign
Source | SS df MS Number of obs = 74
---------|--------+---------+---------+---------+---------+
Model | 1619,2877 2 809,643849 Prob > F = 0,0000
Residual | 824,171761 71 11,608053 R-squared = 0,6627
Total | 2443,45946 73 33,4720474 Root MSE = 3,4071
---------|--------+---------+---------+---------+---------+
mpg | Coef. Std. Err. t P>|t| [95% Conf. Interval]
---------|--------+---------+---------+---------+---------+
weight | -.0065879 .0006371 -10,34 0,000 -.0078583 -.0053175
foreign | -1,650029 1,075994 -1,53 0,130 -3,7955 .4954422
_cons | 41,6797 2,165547 19,25 0,000 37,36172 45,99768
```

You can switch the decimal character back to a period by typing set dp period.

⚠️ Technical note

set dp comma makes drastic changes inside Stata, and we mention this because some older, user-written programs may not be able to deal with those changes. If you are using an older user-written program, you might set dp comma and then find that the program does not work and instead presents some sort of syntax error.

If, using any program, you do get an unanticipated error, try setting dp back to period. See \[D\] format for more information.
Also understand that `set dp comma` affects how Stata outputs numbers, not how it inputs them. You must still use the period to indicate the decimal point on all input. Even with `set dp comma`, you type

```
. replace x=1.5 if x==2
```

### 12.5.3 Date and time formats

Date and time formats are really a numeric format because Stata stores dates as the number of milliseconds, days, weeks, months, quarters, half-years, or years from 01jan1960; see [U] 24 Working with dates and times.

The syntax of the `%t` format is

<table>
<thead>
<tr>
<th>first type</th>
<th>%</th>
<th>to indicate the start of the format</th>
</tr>
</thead>
<tbody>
<tr>
<td>then optionally type</td>
<td>-</td>
<td>if you want the result left-aligned</td>
</tr>
<tr>
<td>then type</td>
<td><code>t</code></td>
<td></td>
</tr>
<tr>
<td>then type</td>
<td><code>character</code></td>
<td>to indicate the units</td>
</tr>
<tr>
<td>then optionally type</td>
<td><code>other characters</code></td>
<td>to indicate how the date/time is to be displayed</td>
</tr>
</tbody>
</table>

The letter you type to specify the units is

- `C` milliseconds from 01jan1960, adjusted for leap seconds
- `c` milliseconds from 01jan1960, ignoring leap seconds
- `d` days from 01jan1960
- `w` weeks from 1960-w1
- `m` calendar months from jan1960
- `q` quarters from 1960-q1
- `h` half years from 1960-h1

There are many codes you can type after that to specify exactly how the date/time is to be displayed, but usually, you do not. Most users use the default `%tc` for date/times and `%td` for dates. See [D] datetime display formats for details.

### 12.5.4 String formats

The syntax for a string format is

<table>
<thead>
<tr>
<th>first type</th>
<th>%</th>
<th>to indicate the start of the format</th>
</tr>
</thead>
<tbody>
<tr>
<td>then optionally type</td>
<td>-</td>
<td>if you want the result left-aligned</td>
</tr>
<tr>
<td>then type</td>
<td>a number</td>
<td>indicating the width of the result</td>
</tr>
<tr>
<td>then type</td>
<td><code>s</code></td>
<td></td>
</tr>
</tbody>
</table>

For instance, `%10s` represents a string format of width 10.

For `strw`, the default format is `%ws` or `%9s`, whichever is wider. For example, a `str10` variable receives a `%10s` format. Strings are displayed right-justified in the field, unless the minus sign is coded; `%10s` would display the string left-aligned.
Example 4

Our automobile data contain a string variable called make.

```
. use http://www.stata-press.com/data/r13/auto
(1978 Automobile Data)
. describe make
    variable name  type          format          label
                  storage        display        value
make             str18          %-18s          Make and Model
```

```
. list make in 63/67

+-------+------------------+
| make  |
|-------|------------------|
| 63.   | Mazda GLC        |
| 64.   | Peugeot 604      |
| 65.   | Renault Le Car   |
| 66.   | Subaru           |
| 67.   | Toyota Celica    |
+-------+------------------+
```

These values are left-aligned because `make` has a display format of `%-18s`. If we want to right-align the values, we could change the format:

```
. format %18s make
. list make in 63/67

+-------+------------------+
| make  |
|-------|------------------|
| 63.   | Mazda GLC        |
| 64.   | Peugeot 604      |
| 65.   | Renault Le Car   |
| 66.   | Subaru           |
| 67.   | Toyota Celica    |
+-------+------------------+
```

12.6 Dataset, variable, and value labels

Labels are strings used to label elements in Stata, such as labels for datasets, variables, and values.

12.6.1 Dataset labels

Associated with every dataset is an 80-character *dataset label*, which is initially set to blanks. You can use the `label data "text"` command to define the dataset label.

Example 5

We have just entered 1980 state data on marriage rates, divorce rates, and median ages. The `describe` command will describe the data in memory:
. describe
Contains data
    obs:     50
    vars:    4
    size:    1,200

<table>
<thead>
<tr>
<th>variable name</th>
<th>storage</th>
<th>display</th>
<th>value</th>
<th>label</th>
<th>variable label</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>str8</td>
<td>%9s</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>median_age</td>
<td>float</td>
<td>%9.0g</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>marriage_rate</td>
<td>long</td>
<td>%12.0g</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>divorce_rate</td>
<td>long</td>
<td>%12.0g</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Sorted by:
    Note: dataset has changed since last saved

describe shows that there are 50 observations on four variables named state, median_age, marriage_rate, and divorce_rate. state is stored as a str8; median_age is stored as a float; and marriage_rate and divorce_rate are both stored as longs. Each variable’s display format (see [U] 12.5 Formats: Controlling how data are displayed) is shown. Finally, the data are not in any particular sort order, and the dataset has changed since it was last saved on disk.

We can label the data by typing label data "1980 state data". We type this and then type describe again:

. label data "1980 state data"
. describe
Contains data
    obs:     50  1980 state data
    vars:    4
    size:    1,200

<table>

Sorted by:
    Note: dataset has changed since last saved

The dataset label is displayed by the describe and use commands.

### 12.6.2 Variable labels

In addition to the name, every variable has associated with it an 80-character variable label. The variable labels are initially set to blanks. You use the label variable varname "text" command to define a new variable label.
Example 6

We have entered data on four variables: state, median_age, marriage_rate, and divorce_rate. describe portrays the data we entered:

```
. describe
Contains data from states.dta
   obs:  50  1980 state data
   vars:  4
   size: 1,200

variable name type format label variable label
--- --- --- --------- --- -------
state str8 %9s
median_age float %9.0g
marriage_rate long %12.0g
divorce_rate long %12.0g
```

Sorted by:
Note: dataset has changed since last saved

We can associate labels with the variables by typing

```
. label variable median_age "Median Age"
. label variable marriage_rate "Marriages per 100,000"
. label variable divorce_rate "Divorces per 100,000"
```

From then on, the result of describe will be

```
. describe
Contains data
   obs:  50  1980 state data
   vars:  4
   size: 1,200

variable name type format label variable label
--- --- --- --------- --- -------
state str8 %9s
median_age float %9.0g Median Age
marriage_rate long %12.0g Marriages per 100,000
divorce_rate long %12.0g Divorces per 100,000
```

Sorted by:
Note: dataset has changed since last saved

Whenever Stata produces output, it will use the variable labels rather than the variable names to label the results if there is room.

12.6.3 Value labels

Value labels define a correspondence or mapping between numeric data and the words used to describe what those numeric values represent. Mappings are named and defined by the label define `lblname # "string" # "string"...` command. The maximum length for the `lblname` is 32 characters. # must be an integer or an extended missing value (.a, .b, ..., .z). The maximum length of string is 32,000 characters. Named mappings are associated with variables by the label values `varname lblname` command.
Example 7

The definition makes value labels sound more complicated than they are in practice. We create a dataset on individuals in which we record a person's sex, coding 0 for males and 1 for females. If our dataset also contained an employee number and salary, it might resemble the following:

```
. use http://www.stata-press.com/data/r13/gxmpl4
(2007 Employee data)
. describe
obs: 7 2007 Employee data
data: 3 11 Feb 2013 15:31
size: 84

storage display value
variable name type format label variable label

empno  float %9.0g Employee number
sex  float %9.0g Sex
salary  float %8.0fc Annual salary, exclusive of bonus

Sorted by:
```

```
. list
+-------+----------+----------+
| empno |   sex    |   salary |
+-------+----------+----------+
|  57213|        0 |   34.000 |
|  47229|        1 |   37.000 |
|  57323|        0 |   34.000 |
|  57401|        0 |   34.500 |
|  57802|        1 |   37.000 |
|  57805|        1 |   34.000 |
|  57824|        0 |   32.500 |
+-------+----------+----------+
```

We could create a mapping called `sexlabel` defining 0 as "Male" and 1 as "Female", and then associate that mapping with the variable `sex` by typing

```
. label define sexlabel 0 "Male" 1 "Female"
. label values sex sexlabel
```

From then on, our data would appear as

```
. describe
obs: 7 2007 Employee data
data: 3 11 Feb 2013 15:31
size: 84

storage display value
variable name type format label variable label

empno  float %9.0g Employee number
sex  float %9.0g sexlabel Sex
salary  float %8.0fc Annual salary, exclusive of bonus

Sorted by:
```
Notice not only that the value label is used to produce words when we list the data but also that the association of the variable `sex` with the value label `sexlabel` is shown by the `describe` command.

---

### Technical note

Value labels and variables may share the same name. For instance, rather than calling the value label `sexlabel` in the example above, we could just as well have named it `sex`. We would then type `label values sex sex` to associate the value label named `sex` with the variable named `sex`.

---

### Example 8

Stata's `encode` and `decode` commands provide a convenient way to go from string variables to numerically coded variables and back again. Let's pretend that, in the example above, rather than coding 0 for males and 1 for females, we created a string variable recording either "male" or "female".

```
. use http://www.stata-press.com/data/r13/gxmpl5
(2007 Employee data)
. describe
Contains data from http://www.stata-press.com/data/r13/gxmpl5.dta
    obs: 7  2007 Employee data
    vars: 3  11 Feb 2013 15:37
    size: 98

storage  display value
variable name type format label variable label
empno    float  %9.0g  Employee number
sex      str6   %9s   Sex
salary   float  %8.0fc Annual salary, exclusive of bonus
```

Sorted by:
We now want to create a numerically encoded variable—we will call it `gender`—from the string variable. We want to do this, say, because we typed `anova salary sex` to perform a one-way ANOVA of salary on sex, and we were told that there were “no observations”. We then remembered that all Stata’s statistical commands treat string variables as if they contain nothing but missing values. The statistical commands work only with numerically coded data.

```stata
. encode sex, generate(gender)
. describe
Contains data from http://www.stata-press.com/data/r13/gxmpl5.dta
    obs: 7 2007 Employee data
    vars: 4 11 Feb 2013 15:37
    size: 126

variable name   type     format     label      variable label
empno           float    %9.0g     Employee number
sex             str6     %9s       Sex
salary          float    %8.0fc   Annual salary, exclusive of bonus
gender          long     %8.0g     gender Sex
```

`encode` adds a new `long` variable called `gender` to the data and defines a new value label called `gender`. The value label `gender` maps 1 to the string `male` and 2 to `female`, so if we were to `list` the data, we could not tell the difference between the `gender` and `sex` variables. However, they are different. Stata’s statistical commands know how to deal with `gender` but do not understand the `sex` variable. See `[D] encode`.

---

**Technical note**

Perhaps rather than employee data, our data are on persons undergoing sex-change operations. There would therefore be two sex variables in our data, sex before the operation and sex after the operation. Assume that the variables are named `presex` and `postsex`. We can associate the same value label to each variable by typing

```stata
. label define sexlabel 0 "Male" 1 "Female"
. label values presex sexlabel
. label values postsex sexlabel
```
Technical note

Stata’s input commands (input and infile) can switch from the words in a value label back to the numeric codes. Remember that encode and decode can translate a string to a numeric mapping and vice versa, so we can map strings to numeric codes either at the time of input or later.

For example,

```
. label define sexlabel 0 "Male" 1 "Female"
. input empno sex:sexlabel salary, label
    empno   sex   salary
  1. 57213  Male  34000
  2. 47229 Female 37000
  3. 57323   0  34000
  4. 57401  Male  34500
  5. 57802 Female 37000
  6. 57805 Female 34000
  7. 57824  Male  32500
  8. end
```

The label define command defines the value label sexlabel. input empno sex:sexlabel salary, label tells Stata to input three variables from the keyboard (empno, sex, and salary), attach the value label sexlabel to the sex variable, and look up any words that are typed in the value label to try to convert them to numbers. To prove that it works, we list the data that we recently entered:

```
. list

    empno   sex   salary
  1. 57213  Male  34000
  2. 47229 Female 37000
  3. 57323  Male  34000
  4. 57401  Male  34500
  5. 57802 Female 37000
  6. 57805 Female 34000
  7. 57824  Male  32500
```

Compare the information we typed for observation 3 with the result listed by Stata. We typed 57323 0 34000. Thus the value of sex in the third observation is 0. When Stata listed the observation, it indicated the value is Male because we told Stata in our label define command that zero is equivalent to Male.

Let’s now add one more observation to our data:

```
. input, label
    empno   sex   salary
  8. 67223 FEmale 33000
'FEmale' cannot be read as a number
  8. 67223 Female 33000
  9. end
```

At first we typed 67223 FEmale 33000, and Stata responded with “'FEmale' cannot be read as a number”. Remember that Stata always respects case, so FEmale is not the same as Female. Stata prompted us to type the line again, and we did so, this time correctly.
Coupled with the automatic option, Stata not only can go from words to numbers but also can create the mapping. Let’s input the data again, but this time, rather than typing the data, let’s read the data from a file. Assume that we have a text file named employee.raw stored on our disk that contains:

57213 Male 34000
47229 Female 37000
57323 Male 34000
57401 Male 34500
57802 Female 37000
57805 Female 34000
57824 Male 32500

The `infile` command can read these data and create the mapping automatically:

```
. label list sexlabel
value label sexlabel not found
r(111);
. infile empno sex:sexlabel salary using employee, automatic
(7 observations read)
```

Our first command, `label list sexlabel`, is only to prove that we had not previously defined the value label `sexlabel`. Stata `infiles` the data without complaint. We now have:

```
. list

empno  sex  salary
      1. 57213  Male  34000
      2. 47229  Female  37000
      3. 57323  Male  34000
      4. 57401  Male  34500
      5. 57802  Female  37000
      6. 57805  Female  34000
      7. 57824  Male  32500
```

Of course, `sex` is just another numeric variable; it does not actually take on the values `Male` and `Female`—it takes on numeric codes that have been automatically mapped to `Male` and `Female`. We can find out what that mapping is by using the `label list` command:

```
. label list sexlabel
sexlabel:
  1  Male
  2  Female
```

We discover that Stata attached the codes 1 to `Male` and 2 to `Female`. Anytime we want to see what our data really look like, ignoring the value labels, we can use the `nolabel` option:
. list, nolabel

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>empno</td>
<td>sex</td>
<td>salary</td>

</tbody>
</table>

12.6.4 Labels in other languages

A dataset can contain labels—data, variable, and value—in up to 100 languages. To discover the languages available for the dataset in memory, type `label language`. You will see this

```
. label language

Language for variable and value labels
In this dataset, value and variable labels have been defined in only one language: default
To create new language: . label language <name>, new
To rename current language: . label language <name>, rename
```

or something like this:

```
. label language

Language for variable and value labels
Available languages:
de
en
sp
Currently set is: . label language sp
To select different language: . label language <name>
To create new language: . label language <name>, new
To rename current language: . label language <name>, rename
```
Right now, the example dataset is set with sp (Spanish) labels:

```
. describe
Contains data
obs: 74  Automóviles, 1978
vars: 12  3 Oct 2012 13:53
size: 3,478
```

<table>
<thead>
<tr>
<th>variable name</th>
<th>storage</th>
<th>display</th>
<th>value</th>
<th>variable label</th>
</tr>
</thead>
<tbody>
<tr>
<td>make</td>
<td>str18</td>

</tr>
<tr>
<td>foreign</td>
<td>byte</td>
<td>%8.0g</td>
<td></td>
<td>Extranjero</td>
</tr>
</tbody>
</table>

Sorted by: foreign

To create labels in more than one language, you set the new language and then define the labels in the standard way; see [D] label language.

### 12.7 Notes attached to data

A dataset may contain notes, which are nothing more than little bits of text that you define and review with the `notes` command. Typing `note`, a colon, and the text defines a note:

```
. note: Send copy to Bob once verified.
```

You can later display whatever notes you have previously defined by typing `notes`:

```
. notes
_dta:
1. Send copy to Bob once verified.
```

Notes are saved with the data, so once you save your dataset, you can replay this note in the future, too.
You can add more notes:

```
. note: Mary wants a copy, too.
. notes
  _dta:
  1. Send copy to Bob once verified.
  2. Mary wants a copy, too.
```

The notes you have added so far are attached to the data generically, which is why Stata prefixes them with `_dta` when it lists them. You can attach notes to variables:

```
. note state: verify values for Nevada.
. note state: what about the two missing values?
. notes
  _dta:
  1. Send copy to Bob once verified.
  2. Mary wants a copy, too.
  state:
  1. verify values for Nevada.
  2. what about the two missing values?
```

When you describe your data, you can see whether notes are attached to the dataset or to any of the variables:

```
. describe
Contains data from states.dta
  obs: 50 1980 state data
  vars: 4
  size: 1,200 (_dta has notes)

<table>
<thead>
<tr>
<th>variable name</th>
<th>type</th>
<th>format</th>
<th>label</th>
<th>variable label</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>str8</td>
<td>%9s</td>
<td>*</td>
<td></td>
</tr>
<tr>
<td>median_age</td>
<td>float</td>
<td>%9.0g</td>
<td>Median Age</td>
<td></td>
</tr>
<tr>
<td>marriage_rate</td>
<td>long</td>
<td>%12.0g</td>
<td>Marriages per 100,000</td>
<td></td>
</tr>
<tr>
<td>divorce_rate</td>
<td>long</td>
<td>%12.0g</td>
<td>Divorces per 100,000</td>
<td>* indicated variables have notes</td>
</tr>
</tbody>
</table>
```

Sorted by:

Note: dataset has changed since last saved

See [D] notes for a complete description of this feature.

### 12.8 Characteristics

Characteristics are an arcane feature of Stata but are of great use to Stata programmers. In fact, the `notes` command described above was implemented using characteristics.

The dataset itself and each variable within the dataset have associated with them a set of characteristics. Characteristics are named and referred to as `varname[charname]`, where `varname` is the name of a variable or `_dta`. The characteristics contain text and are stored with the data in the Stata-format `.dta` dataset, so they are recalled whenever the data are loaded.

How are characteristics used? The [XT] `xt` commands need to know the name of the panel variable, and some of these commands also need to know the name of the time variable. `xtset` is used to specify the panel variable and optionally the time variable. Users need `xtset` their data only once. Stata then remembers this information, even from a different Stata session. Stata does this with
characteristics: \_dta\[iis\] contains the name of the panel variable and \_dta\[tis\] contains the name of the time variable. When an \texttt{xt} command is issued, the command checks these characteristics to obtain the panel and time variables’ names. If this information is not found, then the data have not previously been \texttt{xtset} and an error message is issued. This use of characteristics is hidden from the user—no mention is made of how the commands remember the identity of the panel variable and the time variable.

As a Stata user, you need understand only how to set and clear a characteristic for the few commands that explicitly reveal their use of characteristics. You set a variable \texttt{varname}’s characteristic \texttt{charname} to \texttt{x} by typing
\begin{verbatim}
   . char varname[\texttt{charname}] \texttt{x}
\end{verbatim}
You set the data’s characteristic \texttt{charname} to be \texttt{x} by typing
\begin{verbatim}
   . char \_dta[\texttt{charname}] \texttt{x}
\end{verbatim}
You clear a characteristic by typing
\begin{verbatim}
   . char varname[\texttt{charname}]
\end{verbatim}
where \texttt{varname} is either a variable name or \_dta. You can clear a characteristic, even if it has never been set.

The most important feature of characteristics is that Stata remembers them from one session to the next; they are saved with the data.

### Technical note

Programmers will want to know more. A technical description is found in \texttt{[P] char}, but for an overview, you may refer to \texttt{varname}’s \texttt{charname} characteristic by embedding its name in single quotes and typing ‘\texttt{varname[\texttt{charname}]}; see \texttt{[U] 18.3.13 Referring to characteristics}.

You can fetch the names of all characteristics associated with \texttt{varname} by typing
\begin{verbatim}
   . local macname : char varname[]
\end{verbatim}
The maximum length of the contents of a characteristic is 13,400 characters for Small Stata and 67,784 characters for Stata/IC, Stata/SE, and Stata/MP. The association of names with characteristics is by convention. If you, as a programmer, wish to create new characteristics for use in your ado-files, do so, but include at least one capital letter in the characteristic name. The current convention reserves all lowercase names for “official” Stata.

### 12.9 Data Editor and Variables Manager

We have spent most of this chapter writing about data management performed from Stata’s command line. However, Stata provides two powerful features in its interface to help you examine and manage your data: the Data Editor and the Variables Manager.

The Data Editor is a spreadsheet-style data editor that allows you to enter new data, edit existing data, safely browse your data in a read-only mode, and perform almost any data management task you desire in a reproducible manner using a graphical interface. To open the Data Editor, select \texttt{Data} \textgreater{} \texttt{Data Editor} \textgreater{} \texttt{Data Editor (Edit)} or \texttt{Data} \textgreater{} \texttt{Data Editor} \textgreater{} \texttt{Data Editor (Browse)}. See \texttt{GS} 6 \texttt{Using the Data Editor} (GSM, GSU, or GSW) for a tutorial discussion of the Data Editor. See \texttt{D edit} for technical details.
The Variables Manager is a tool that lists and allows you to manage all the properties of the variables in your data. Variable properties include the name, label, storage type, format, value label, and notes. The Variables Manager allows you to sort and filter your variables, something that you will find to be very useful if you work with datasets having many variables. The Variables Manager also can be used to create varlists for the Command window. To open the Variables Manager, select Data > Variables Manager. See [GS] 7 Using the Variables Manager (GSM, GSU, or GSW) for a tutorial discussion of the Variables Manager.

Both the Data Editor and Variables Manager submit commands to Stata to perform any changes that you request. This lets you see a log of what changes were made, and it also allows you to work interactively while still building a list of commands you can execute later to reproduce your analysis.
