A panel variable must be specified. For xtivreg, fd a time variable must also be specified. Use xtset; see [XT] xtset.

*varlist*<sub>1</sub> and *varlist*<sub>iv</sub> may contain factor variables, except for the fd estimator; see [U] **11.4.3 Factor variables**. *depvar, varlist*<sub>1</sub>, *varlist*<sub>2</sub>, and *varlist*<sub>iv</sub> may contain time-series operators; see [U] **11.4.4 Time-series varlist**. by and statsby are allowed; see [U] **11.1.10 Prefix commands**.

coeflegend does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Statistics > Longitudinal/panel data > Endogenous covariates > Instrumental-variables regression (FE, RE, BE, FD)

## Description

xtivreg offers five different estimators for fitting panel-data models in which some of the righthand-side covariates are endogenous. These estimators are two-stage least-squares generalizations of simple panel-data estimators for exogenous variables. xtivreg with the be option uses the twostage least-squares between estimator. xtivreg with the fe option uses the two-stage least-squares within estimator. xtivreg with the re option uses a two-stage least-squares random-effects estimator. There are two implementations: G2SLS from Balestra and Varadharajan-Krishnakumar (1987) and EC2SLS from Baltagi. The Balestra and Varadharajan-Krishnakumar G2SLS is the default because it is computationally less expensive. Baltagi's EC2SLS can be obtained by specifying the ec2sls option. xtivreg with the fd option requests the two-stage least-squares first-differenced estimator.

See Baltagi (2013) for an introduction to panel-data models with endogenous covariates. For the derivation and application of the first-differenced estimator, see Anderson and Hsiao (1981).

## **Options for RE model**

Model

re requests the G2SLS random-effects estimator. re is the default.

- ec2s1s requests Baltagi's EC2SLS random-effects estimator instead of the default Balestra and Varadharajan-Krishnakumar estimator.
- nosa specifies that the Baltagi-Chang estimators of the variance components be used instead of the default adapted Swamy-Arora estimators.
- regress specifies that all the covariates be treated as exogenous and that the instrument list be ignored. Specifying regress causes xtivreg to fit the requested panel-data regression model of *depvar* on *varlist*<sub>1</sub> and *varlist*<sub>2</sub>, ignoring *varlist*<sub>iv</sub>.

SE ]

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (conventional) and that use bootstrap or jackknife methods (bootstrap, jackknife); see [XT] vce\_options.

vce(conventional), the default, uses the conventionally derived variance estimator for generalized least-squares regression.

Reporting

level(#); see [R] estimation options.

first specifies that the first-stage regressions be displayed.

- small specifies that t statistics be reported instead of Z statistics and that F statistics be reported instead of  $\chi^2$  statistics.
- theta specifies that the output include the estimated value of  $\theta$  used in combining the between and fixed estimators. For balanced data, this is a constant, and for unbalanced data, a summary of the values is presented in the header of the output.
- display\_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] estimation options.

The following option is available with xtivreg but is not shown in the dialog box:

coeflegend; see [R] estimation options.

## Options for BE model

\_ Model

be requests the between regression estimator.

regress specifies that all the covariates are to be treated as exogenous and that the instrument list is to be ignored. Specifying regress causes xtivreg to fit the requested panel-data regression model of *depvar* on *varlist*<sub>1</sub> and *varlist*<sub>2</sub>, ignoring *varlist*<sub>iv</sub>.

SE

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (conventional) and that use bootstrap or jackknife methods (bootstrap, jackknife); see [XT] vce\_options.

vce(conventional), the default, uses the conventionally derived variance estimator for generalized least-squares regression.

Reporting

level(#); see [R] estimation options.

first specifies that the first-stage regressions be displayed.

- small specifies that t statistics be reported instead of Z statistics and that F statistics be reported instead of  $\chi^2$  statistics.
- display\_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] estimation options.

The following option is available with xtivreg but is not shown in the dialog box:

coeflegend; see [R] estimation options.

## **Options for FE model**

Model

fe requests the fixed-effects (within) regression estimator.

regress specifies that all the covariates are to be treated as exogenous and that the instrument list is to be ignored. Specifying regress causes xtivreg to fit the requested panel-data regression model of *depvar* on *varlist*<sub>1</sub> and *varlist*<sub>2</sub>, ignoring *varlist*<sub>iv</sub>.

SE

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (conventional) and that use bootstrap or jackknife methods (bootstrap, jackknife); see [XT] vce\_options.

vce(conventional), the default, uses the conventionally derived variance estimator for generalized least-squares regression.

Reporting

level(#); see [R] estimation options.

- first specifies that the first-stage regressions be displayed.
- small specifies that t statistics be reported instead of Z statistics and that F statistics be reported instead of  $\chi^2$  statistics.
- display\_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] estimation options.

The following option is available with xtivreg but is not shown in the dialog box: coeflegend; see [R] estimation options.

### Options for FD model

Model

noconstant; see [R] estimation options.

fd requests the first-differenced regression estimator.

regress specifies that all the covariates are to be treated as exogenous and that the instrument list is to be ignored. Specifying regress causes xtivreg to fit the requested panel-data regression model of *depvar* on *varlist*<sub>1</sub> and *varlist*<sub>2</sub>, ignoring *varlist*<sub>iv</sub>.

SE

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (conventional) and that use bootstrap or jackknife methods (bootstrap, jackknife); see [XT] vce\_options.

vce(conventional), the default, uses the conventionally derived variance estimator for generalized least-squares regression.

Reporting

level(#); see [R] estimation options.

first specifies that the first-stage regressions be displayed.

- small specifies that t statistics be reported instead of Z statistics and that F statistics be reported instead of  $\chi^2$  statistics.
- display\_options: noomitted, vsquish, cformat(% fmt), pformat(% fmt), sformat(% fmt), and nolstretch; see [R] estimation options.

The following option is available with xtivreg but is not shown in the dialog box:

coeflegend; see [R] estimation options.

### Remarks and examples

If you have not read [XT] **xt**, please do so.

Consider an equation of the form

$$y_{it} = \mathbf{Y}_{it}\boldsymbol{\gamma} + \mathbf{X}_{1it}\boldsymbol{\beta} + \mu_i + \nu_{it} = \mathbf{Z}_{it}\boldsymbol{\delta} + \mu_i + \nu_{it} \tag{1}$$

where

 $y_{it}$  is the dependent variable;

 $\mathbf{Y}_{it}$  is an  $1 \times g_2$  vector of observations on  $g_2$  endogenous variables included as covariates, and these variables are allowed to be correlated with the  $\nu_{it}$ ;

 $\mathbf{X}_{1it}$  is an  $1 \times k_1$  vector of observations on the exogenous variables included as covariates;

#### stata.com

 $\mathbf{Z}_{it} = [\mathbf{Y}_{it} \ \mathbf{X}_{it}];$ 

 $\gamma$  is a  $g_2 \times 1$  vector of coefficients;

 $\boldsymbol{\beta}$  is a  $k_1 \times 1$  vector of coefficients; and

 $\boldsymbol{\delta}$  is a  $K \times 1$  vector of coefficients, where  $K = g_2 + k_1$ .

Assume that there is a  $1 \times k_2$  vector of observations on the  $k_2$  instruments in  $\mathbf{X}_{2it}$ . The order condition is satisfied if  $k_2 \ge g_2$ . Let  $\mathbf{X}_{it} = [\mathbf{X}_{1it} \ \mathbf{X}_{2it}]$ . **xtivreg** handles exogenously unbalanced panel data. Thus define  $T_i$  to be the number of observations on panel *i*, *n* to be the number of panels and *N* to be the total number of observations; that is,  $N = \sum_{i=1}^{n} T_i$ .

**xtivreg** offers five different estimators, which may be applied to models having the form of (1). The first-differenced estimator (FD2SLS) removes the  $\mu_i$  by fitting the model in first differences. The within estimator (FE2SLS) fits the model after sweeping out the  $\mu_i$  by removing the panel-level means from each variable. The between estimator (BE2SLS) models the panel averages. The two random-effects estimators, G2SLS and EC2SLS, treat the  $\mu_i$  as random variables that are independent and identically distributed (i.i.d.) over the panels. Except for (FD2SLS), all of these estimators are generalizations of estimators in **xtreg**. See [XT] **xtreg** for a discussion of these estimators for exogenous covariates.

Although the estimators allow for different assumptions about the  $\mu_i$ , all the estimators assume that the idiosyncratic error term  $\nu_{it}$  has zero mean and is uncorrelated with the variables in  $\mathbf{X}_{it}$ . Just as when there are no endogenous covariates, as discussed in [XT] **xtreg**, there are various perspectives on what assumptions should be placed on the  $\mu_i$ . If they are assumed to be fixed, the  $\mu_i$  may be correlated with the variables in  $\mathbf{X}_{it}$ , and the within estimator is efficient within a class of limited information estimators. Alternatively, if the  $\mu_i$  are assumed to be random, they are also assumed to be i.i.d. over the panels. If the  $\mu_i$  are assumed to be uncorrelated with the variables in  $\mathbf{X}_{it}$ , the GLS random-effects estimators are more efficient than the within estimator. However, if the  $\mu_i$  are correlated with the variables in  $\mathbf{X}_{it}$ , the random-effects estimators are inconsistent but the within estimator is consistent. The price of using the within estimator is that it is not possible to estimate coefficients on time-invariant variables, and all inference is conditional on the  $\mu_i$  in the sample. See Mundlak (1978) and Hsiao (2003) for discussions of this interpretation of the within estimator.

#### Example 1: Fixed-effects model

For the within estimator, consider another version of the wage equation discussed in [XT] **xtreg**. The data for this example come from an extract of women from the National Longitudinal Survey of Youth that was described in detail in [XT] **xt**. Restricting ourselves to only time-varying covariates, we might suppose that the log of the real wage was a function of the individual's age, age<sup>2</sup>, her tenure in the observed place of employment, whether she belonged to union, whether she lives in metropolitan area, and whether she lives in the south. The variables for these are, respectively, age, c.age#c.age, tenure, union, not\_smsa, and south. If we treat all the variables as exogenous, we can use the one-stage within estimator from xtreg, yielding

. use http://w (National Long	www.stata-pre gitudinal Sur	ss.com/data/ vey. Young	r13/nlswo Women 14–	ork -26 years	of age in 1	968)
. xtreg ln_w a	age c.age#c.a	ge tenure no	t_smsa ur	nion sout	h, fe	
Fixed-effects Group variable	(within) reg e: idcode	ression		Number Number	of obs of groups	= 19007 = 4134
R-sq: within betweer overall	= 0.1333 n = 0.2375 L = 0.2031			Obs per	group: min avg max	= 1 = 4.6 = 12
corr(u_i, Xb)	= 0.2074			F(6,148 Prob >	67) F	= 381.19 = 0.0000
ln_wage	Coef.	Std. Err.	t	P> t	[95% Conf	. Interval]
age	.0311984	.0033902	9.20	0.000	.0245533	.0378436
c.age#c.age	0003457	.0000543	-6.37	0.000	0004522	0002393
tenure	.0176205	.0008099	21.76	0.000	.0160331	.0192079
not_smsa	0972535	.0125377	-7.76	0.000	1218289	072678
union	.0975672	.0069844	13.97	0.000	.0838769	.1112576
south	0620932	.013327	-4.66	0.000	0882158	0359706
_cons	1.091612	.0523126	20.87	0.000	.9890729	1.194151
sigma_u sigma_e rho	.3910683 .25545969 .70091004	(fraction	of variar	nce due t	o u_i)	
F test that al	ll u_i=0:	F(4133, 148	67) =	8.31	Prob >	F = 0.0000

All the coefficients are statistically significant and have the expected signs.

Now suppose that we wish to model tenure as a function of union and south and that we believe that the errors in the two equations are correlated. Because we are still interested in the within estimates, we now need a two-stage least-squares estimator. The following output shows the command and the results from fitting this model:

. xtivreg ln_v	w age c.age#c.	.age not_sms	a (tenur	e = unio	on south), fe	
Fixed-effects Group variable	(within) IV 1 e: idcode	regression	N N	umber of umber of	obs = groups =	19007 4134
R-sq: within between overal	= . n = 0.1304 l = 0.0897		0	bs per gr	coup: min = avg = max =	1 4.6 12

ln_wage	Coef.	Std. Err.	z	P> z	[95% Conf	. Interval]
tenure age c.age#c.age not_smsa	.2403531 .0118437 0012145 0167178	.0373419 .0090032 .0001968 .0339236	6.44 1.32 -6.17 -0.49	0.000 0.188 0.000 0.622	.1671643 0058023 0016003 0832069	.3135419 .0294897 0008286 .0497713
	.70661941 .63029359 .55690561	(fraction	of varia	nce due t	:0 u_i)	
F test that a	all u_i=0:	F(4133,148	69) =	1.44	Prob > F	= 0.0000
Instrumented: Instruments:	tenure age c.age#d	c.age not_sm	sa union	south		

Although all the coefficients still have the expected signs, the coefficients on age and not\_smsa are no longer statistically significant. Given that these variables have been found to be important in many other studies, we might want to rethink our specification.

If we are willing to assume that the  $\mu_i$  are uncorrelated with the other covariates, we can fit a random-effects model. The model is frequently known as the variance-components or error-components model. xtivreg has estimators for two-stage least-squares one-way error-components models. In the one-way framework, there are two variance components to estimate, the variance of the  $\mu_i$  and the variance of the  $\nu_{it}$ . Because the variance components are unknown, consistent estimates are required to implement feasible GLS. xtivreg offers two choices: a Swamy-Arora method and simple consistent estimators from Baltagi and Chang (2000).

Baltagi and Chang (1994) derived the Swamy-Arora estimators of the variance components for unbalanced panels. By default, xtivreg uses estimators that extend these unbalanced Swamy-Arora estimators to the case with instrumental variables. The default Swamy-Arora method contains a degree-of-freedom correction to improve its performance in small samples. Baltagi and Chang (2000) use variance-components estimators, which are based on the ideas of Amemiya (1971) and Swamy and Arora (1972), but they do not attempt to make small-sample adjustments. These consistent estimators of the variance components will be used if the nosa option is specified.

Using either estimator of the variance components, xtivreg offers two GLS estimators of the random-effects model. These two estimators differ only in how they construct the GLS instruments from the exogenous and instrumental variables contained in  $\mathbf{X}_{it} = [\mathbf{X}_{1it} \ \mathbf{X}_{2it}]$ . The default method, G2SLS, which is from Balestra and Varadharajan-Krishnakumar, uses the exogenous variables after they have been passed through the feasible GLS transform. In math, G2SLS uses  $\mathbf{X}_{it}^*$  for the GLS instruments, where  $\mathbf{X}_{it}^*$  is constructed by passing each variable in  $\mathbf{X}_{it}$  through the GLS transform in (3) given in *Methods and formulas*. If the ec2sls option is specified, xtivreg performs Baltagi's

EC2SLS. In EC2SLS, the instruments are  $\widetilde{\mathbf{X}}_{it}$  and  $\overline{\mathbf{X}}_{it}$ , where  $\widetilde{\mathbf{X}}_{it}$  is constructed by passing each of the variables in  $\mathbf{X}_{it}$  through the within transform, and  $\overline{\mathbf{X}}_{it}$  is constructed by passing each variable through the between transform. The within and between transforms are given in the *Methods and formulas* section. Baltagi and Li (1992) show that, although the G2SLS instruments are a subset of those contained in EC2SLS, the extra instruments in EC2SLS are redundant in the sense of White (2001). Given the extra computational cost, G2SLS is the default.

### Example 2: GLS random-effects model

Here is the output from applying the G2SLS estimator to this model:

. xtivreg ln_w	1 age c.age#c.	age not_sms	a 2.race	(tenure	= union	birth	south),	re
G2SLS random-e Group variable	effects IV reg e: idcode	gression		Number Number	of obs of group	= ps =	190 41	07 34
R-sq: within between overall	= 0.0664 n = 0.2098 L = 0.1463			Obs per	group:	min = avg = max =	4	1 .6 12
corr(u_i, X)	= 0 (ass	sumed)		Wald ch Prob >	i2(5) chi2	=	1446. 0.00	37 00
ln_wage	Coef.	Std. Err.	z	P> z	[95%	Conf.	Interva	1]
tenure age	.1391798 .0279649	.0078756 .0054182	17.67 5.16	0.000	.123 .0173	3744 3454	.15461 .03858	57 43
c.age#c.age	0008357	.0000871	-9.60	0.000	0010	0063	0006	65
not_smsa	2235103	.0111371	-20.07	0.000	2453	3386	20168	21
race black _cons	2078613 1.337684	.0125803 .0844988	-16.52 15.83	0.000	2329 1.172	5183 2069	18320 1.5032	44 99
sigma_u sigma_e rho	.36582493 .63031479 .25197078	(fraction	of varia	nce due t	o u_i)			
Instrumented: Instruments:	tenure age c.age#c	.age not_sm	sa 2.rac	e union b	irth_yr	south		-

We have included two time-invariant covariates, birth\_yr and 2.race. All the coefficients are statistically significant and are of the expected sign.

Applying the EC2SLS estimator yields similar results:

<pre>. xtivreg ln_v &gt; ec2sls</pre>	age c.age#c.	.age not_sms	a 2.race	(tenure	= union	birth	south), re

#### Example 3: First-differenced estimator

The two-stage least-squares first-differenced estimator (FD2SLS) has been used to fit both fixed-effect and random-effect models. If the  $\mu_i$  are truly fixed-effects, the FD2SLS estimator is not as efficient as the two-stage least-squares within estimator for finite  $T_i$ . Similarly, if none of the endogenous variables are lagged dependent variables, the exogenous variables are all strictly exogenous, and the random effects are i.i.d. and independent of the  $X_{it}$ , the two-stage GLS estimators are more efficient than the FD2SLS estimator. However, the FD2SLS estimator has been used to obtain consistent estimates when one of these conditions fails. Anderson and Hsiao (1981) used a version of the FD2SLS estimator to fit a panel-data model with a lagged dependent variable.

Arellano and Bond (1991) develop new one-step and two-step GMM estimators for dynamic panel data. See [XT] **xtabond** for a discussion of these estimators and Stata's implementation of them. In their article, Arellano and Bond (1991) apply their new estimators to a model of dynamic labor demand that had previously been considered by Layard and Nickell (1986). They also compare the results of their estimators with those from the Anderson–Hsiao estimator using data from an unbalanced panel of firms from the United Kingdom. As is conventional, all variables are indexed over the firm *i* and time *t*. In this dataset,  $n_{it}$  is the log of employment in firm *i* inside the United Kingdom at time *t*,  $w_{it}$  is the natural log of the real product wage,  $k_{it}$  is the natural log of the gross capital stock, and  $ys_{it}$  is the natural log of industry output. The model also includes time dummies yr1980, yr1981, yr1982, yr1983, and yr1984. In Arellano and Bond (1991, table 5, column e), the authors present the results from applying one version of the Anderson–Hsiao estimator to these data. This example reproduces their results for the coefficients, though standard errors are different because Arellano and Bond are using robust standard errors.

### Methods and formulas

Consider an equation of the form

$$y_{it} = \mathbf{Y}_{it}\boldsymbol{\gamma} + \mathbf{X}_{1it}\boldsymbol{\beta} + \mu_i + \nu_{it} = \mathbf{Z}_{it}\boldsymbol{\delta} + \mu_i + \nu_{it}$$
(2)

where

 $y_{it}$  is the dependent variable;

 $\mathbf{Y}_{it}$  is an  $1 imes g_2$  vector of observations on  $g_2$  endogenous variables included as covariates,

and these variables are allowed to be correlated with the  $\nu_{it}$ ;

 $\mathbf{X}_{1it}$  is an  $1 \times k_1$  vector of observations on the exogenous variables included as covariates;  $\mathbf{Z}_{it} = [\mathbf{Y}_{it} \ \mathbf{X}_{it}];$ 

 $\gamma$  is a  $g_2 \times 1$  vector of coefficients;

 $\beta$  is a  $k_1 \times 1$  vector of coefficients; and

 $\boldsymbol{\delta}$  is a  $K \times 1$  vector of coefficients, where  $K = g_2 + k_1$ .

Assume that there is a  $1 \times k_2$  vector of observations on the  $k_2$  instruments in  $\mathbf{X}_{2it}$ . The order condition is satisfied if  $k_2 \ge g_2$ . Let  $\mathbf{X}_{it} = [\mathbf{X}_{1it} \ \mathbf{X}_{2it}]$ . **xtivreg** handles exogenously unbalanced panel data. Thus define  $T_i$  to be the number of observations on panel *i*, *n* to be the number of panels, and *N* to be the total number of observations; that is,  $N = \sum_{i=1}^{n} T_i$ .

Methods and formulas are presented under the following headings:

xtivreg, fd xtivreg, fe xtivreg, be xtivreg, re

### xtivreg, fd

As the name implies, this estimator obtains its estimates and conventional VCE from an instrumentalvariables regression on the first-differenced data. Specifically, first differencing the data yields

$$y_{it} - y_{it-1} = (\mathbf{Z}_{it} - \mathbf{Z}_{i,t-1}) \,\delta + \nu_{it} - \nu_{i,t-1}$$

With the  $\mu_i$  removed by differencing, we can obtain the estimated coefficients and their estimated variance–covariance matrix from a standard two-stage least-squares regression of  $\Delta y_{it}$  on  $\Delta \mathbf{Z}_{it}$  with instruments  $\Delta \mathbf{X}_{it}$ .

$$R^{2} \text{ within is reported as } \left[\operatorname{corr}\left\{\left(\mathbf{Z}_{it}-\overline{\mathbf{Z}}_{i}\right)\widehat{\boldsymbol{\delta}},y_{it}-\overline{y}_{i}\right\}\right]^{2}$$
$$R^{2} \text{ between is reported as } \left\{\operatorname{corr}\left(\overline{\mathbf{Z}}_{i}\widehat{\boldsymbol{\delta}},\overline{y}_{i}\right)\right\}^{2}.$$
$$R^{2} \text{ overall is reported as } \left\{\operatorname{corr}\left(\mathbf{Z}_{it}\widehat{\boldsymbol{\delta}},y_{it}\right)\right\}^{2}.$$

#### xtivreg, fe

At the heart of this model is the within transformation. The within transform of a variable w is

$$\widetilde{w}_{it} = w_{it} - \overline{w}_{i.} + \overline{w}$$

where

$$\overline{w}_{i.} = \frac{1}{n} \sum_{t=1}^{T_i} w_{it}$$
$$\overline{w} = \frac{1}{N} \sum_{i=1}^{n} \sum_{t=1}^{T_i} w_{it}$$

and n is the number of groups and N is the total number of observations on the variable.

The within transform of (2) is

$$\widetilde{y}_{it} = \widetilde{\mathbf{Z}}_{it} + \widetilde{\nu}_{it}$$

The within transform has removed the  $\mu_i$ . With the  $\mu_i$  gone, the within 2SLS estimator can be obtained from a two-stage least-squares regression of  $\tilde{y}_{it}$  on  $\tilde{\mathbf{Z}}_{it}$  with instruments  $\tilde{\mathbf{X}}_{it}$ .

Suppose that there are K variables in  $\mathbf{Z}_{it}$ , including the mandatory constant. There are K + n - 1 parameters estimated in the model, and the conventional VCE for the within estimator is

$$\frac{N-K}{N-n-K+1}V_{IV}$$

where  $V_{IV}$  is the VCE from the above two-stage least-squares regression.

From the estimate of  $\hat{\delta}$ , estimates  $\hat{\mu}_i$  of  $\mu_i$  are obtained as  $\hat{\mu}_i = \overline{y}_i - \overline{\mathbf{Z}}_i \hat{\delta}$ . Reported from the calculated  $\hat{\mu}_i$  is its standard deviation and its correlation with  $\overline{\mathbf{Z}}_i \hat{\delta}$ . Reported as the standard deviation of  $\nu_{it}$  is the regression's estimated root mean squared error,  $s^2$ , which is adjusted (as previously stated) for the n-1 estimated means.

 $\mathbb{R}^2$  within is reported as the  $\mathbb{R}^2$  from the mean-deviated regression.

$$R^2$$
 between is reported as  $\left\{ \operatorname{corr}(\overline{\mathbf{Z}}_i \widehat{\boldsymbol{\delta}}, \overline{y}_i) \right\}^2$ .  
 $R^2$  overall is reported as  $\left\{ \operatorname{corr}(\mathbf{Z}_{it} \widehat{\boldsymbol{\delta}}, y_{it}) \right\}^2$ .

At the bottom of the output, an F statistics against the null hypothesis that all the  $\mu_i$  are zero is reported. This F statistic is an application of the results in Wooldridge (1990).

#### xtivreg, be

After passing (2) through the between transform, we are left with

$$\overline{y}_i = \alpha + \overline{\mathbf{Z}}_i \boldsymbol{\delta} + \mu_i + \overline{\nu}_i \tag{3}$$

where

$$\overline{w}_i = rac{1}{T_i} \sum_{t=1}^{T_i} w_{it} \quad ext{ for } w \in \{y, \mathbf{Z}, 
u\}$$

Similarly, define  $\overline{\mathbf{X}}_i$  as the matrix of instruments  $\mathbf{X}_{it}$  after they have been passed through the between transform.

The BE2SLS estimator of (3) obtains its coefficient estimates and its conventional VCE, a two-stage least-squares regression of  $\overline{y}_i$  on  $\overline{Z}_i$  with instruments  $\overline{\mathbf{X}}_i$  in which each average appears  $T_i$  times.

 $\mathbb{R}^2$  between is reported as the  $\mathbb{R}^2$  from the fitted regression.

$$R^2$$
 within is reported as  $\left[\operatorname{corr}\left\{(\mathbf{Z}_{it} - \overline{\mathbf{Z}}_i)\widehat{\delta}, y_{it} - \overline{y}_i\right\}\right]^2$ .  
 $R^2$  overall is reported as  $\left\{\operatorname{corr}(\mathbf{Z}_{it}\widehat{\delta}, y_{it})\right\}^2$ .

#### xtivreg, re

Per Baltagi and Chang (2000), let

$$u = \mu_i + \nu_{it}$$

be the  $N \times 1$  vector of combined errors. Then under the assumptions of the random-effects model,

$$E(uu') = \sigma_{\nu}^{2} \operatorname{diag}\left[I_{T_{i}} - \frac{1}{T_{i}} \boldsymbol{\iota}_{T_{i}} \boldsymbol{\iota}_{T_{i}}'\right] + \operatorname{diag}\left[w_{i} \frac{1}{T_{i}} \boldsymbol{\iota}_{T_{i}} \boldsymbol{\iota}_{T_{i}}'\right]$$

where

$$\omega_i = T_i \sigma_\mu^2 + \sigma_\nu^2$$

and  $\iota_{T_i}$  is a vector of ones of dimension  $T_i$ .

Because the variance components are unknown, consistent estimates are required to implement feasible GLS. xtivreg offers two choices. The default is a simple extension of the Swamy-Arora method for unbalanced panels.

Let

$$u_{it}^w = \widetilde{y}_{it} - \widetilde{\mathbf{Z}}_{it}\widehat{\boldsymbol{\delta}}_w$$

be the combined residuals from the within estimator. Let  $\tilde{u}_{it}$  be the within-transformed  $u_{it}$ . Then

$$\widehat{\sigma}_{\nu} = \frac{\sum_{i=1}^{n} \sum_{t=1}^{T_i} \widetilde{u}_{it}^2}{N - n - K + 1}$$

Let

$$u_{it}^b = y_{it} - \mathbf{Z}_{it} \boldsymbol{\delta}_b$$

be the combined residual from the between estimator. Let  $\overline{u}_{i.}^{b}$  be the between residuals after they have been passed through the between transform. Then

$$\widehat{\sigma}_{\mu}^{2} = \frac{\sum_{i=1}^{n} \sum_{t=1}^{T_{i}} \overline{u}_{it}^{2} - (n-K)\widehat{\sigma}_{\nu}^{2}}{N-r}$$

where

$$r = \operatorname{trace}\left\{ \left( \overline{\mathbf{Z}}_{i}^{'} \overline{\mathbf{Z}}_{i} \right)^{-1} \overline{\mathbf{Z}}_{i}^{'} \mathbf{Z}_{\mu} \mathbf{Z}_{\mu}^{'} \overline{\mathbf{Z}}_{i} \right\}$$

where

$$\mathbf{Z}_{\mu}= ext{diag}\left(oldsymbol{\iota}_{T_{i}}oldsymbol{\iota}_{T_{i}}^{'}
ight)$$

If the nosa option is specified, the consistent estimators described in Baltagi and Chang (2000) are used. These are given by

$$\widehat{\sigma}_{\nu} = \frac{\sum_{i=1}^{n} \sum_{t=1}^{T_i} \widetilde{u}_{it}^2}{N - n}$$

and

$$\widehat{\sigma}_{\mu}^{2} = \frac{\sum_{i=1}^{n} \sum_{t=1}^{T_{i}} \overline{u}_{it}^{2} - n \widehat{\sigma}_{\nu}^{2}}{N}$$

The default Swamy–Arora method contains a degree-of-freedom correction to improve its performance in small samples.

Given estimates of the variance components,  $\hat{\sigma}_{\nu}^2$  and  $\hat{\sigma}_{\mu}^2$ , the feasible GLS transform of a variable w is

$$w^* = w_{it} - \widehat{\theta}_{it} \overline{w}_{i.} \tag{4}$$

where

$$\overline{w}_{i.} = \frac{1}{T_i} \sum_{t=1}^{T_i} w_{it}$$

$$\widehat{\theta}_{it} = 1 - \left(\frac{\widehat{\sigma}_{\nu}^2}{\widehat{\omega}_i}\right)^{-\frac{1}{2}}$$

and

$$\widehat{\omega}_i = T_i \widehat{\sigma}_{\mu}^2 + \widehat{\sigma}_{\nu}^2$$

Using either estimator of the variance components, xtivreg contains two GLS estimators of the random-effects model. These two estimators differ only in how they construct the GLS instruments from the exogenous and instrumental variables contained in  $X_{it} = [X_{1it}X_{2it}]$ . The default method, G2SLS, which is from Balestra and Varadharajan-Krishnakumar, uses the exogenous variables after they have been passed through the feasible GLS transform. Mathematically, G2SLS uses  $X^*$  for the GLS instruments, where  $X^*$  is constructed by passing each variable in X though the GLS transform in (4). The G2SLS estimator obtains its coefficient estimates and conventional VCE from an instrumental variable regression of  $y_{it}^*$  on  $Z_{it}^*$  with instruments  $X_{it}^*$ .

If the ec2s1s option is specified, xtivreg performs Baltagi's EC2SLS. In EC2SLS, the instruments are  $\widetilde{\mathbf{X}}_{it}$  and  $\overline{\mathbf{X}}_{it}$ , where  $\widetilde{X}_{it}$  is constructed by each of the variables in  $\mathbf{X}_{it}$  throughout the GLS transform in (4), and  $\overline{\mathbf{X}}_{it}$  is made of the group means of each variable in  $\mathbf{X}_{it}$ . The EC2SLS estimator obtains its coefficient estimates and its VCE from an instrumental variables regression of  $y_{it}^*$  on  $\mathbf{Z}_{it}^*$  with instruments  $\widetilde{\mathbf{X}}_{it}$  and  $\overline{\mathbf{X}}_{it}$ .

Baltagi and Li (1992) show that although the G2SLS instruments are a subset of those in EC2SLS, the extra instruments in EC2SLS are redundant in the sense of White (2001). Given the extra computational cost, G2SLS is the default.

The standard deviation of  $\mu_i + \nu_{it}$  is calculated as  $\sqrt{\hat{\sigma}_{\mu}^2 + \hat{\sigma}_{\nu}^2}$ .

 $R^{2} \text{ between is reported as } \left\{ \operatorname{corr}(\overline{\mathbf{Z}}_{i}\widehat{\boldsymbol{\delta}}, \overline{y}_{i}) \right\}^{2}.$   $R^{2} \text{ within is reported as } \left[ \operatorname{corr}\left\{ (\mathbf{Z}_{it} - \overline{\mathbf{Z}}_{i})\widehat{\boldsymbol{\delta}}, y_{it} - \overline{y}_{i} \right\} \right]^{2}.$   $R^{2} \text{ overall is reported as } \left\{ \operatorname{corr}(\mathbf{Z}_{it}\widehat{\boldsymbol{\delta}}, y_{it}) \right\}^{2}.$
