> Description   Quick start   Menu   Syntax
> Options   Remarks and examples   Also see

Description

append appends Stata-format datasets stored on disk to the end of the dataset in memory. If any *filename* is specified without an extension, .dta is assumed.

Stata can also join observations from two datasets into one; see [D] **merge**. See [U] **22 Combining datasets** for a comparison of append, merge, and joinby.

Quick start

Append mydata2.dta to mydata1.dta with no data in memory
     append using mydata1 mydata2

As above, but with mydata1.dta in memory
     append using mydata2

As above, and generate newv to indicate source dataset
     append using mydata2, generate(newv)

As above, but do not copy value labels or notes from mydata2.dta
     append using mydata2, generate(newv) nolabel nonotes

Only keep v1, v2, and v3 from mydata2.dta
     append using mydata2, keep(v1 v2 v3)

Menu

Data > Combine datasets > Append datasets

Syntax

> append using *filename* [*filename* ...] [, *options*]

You may enclose *filename* in double quotes and must do so if *filename* contains blanks or other special characters.

options	Description
generate(*newvar*)	*newvar* marks source of resulting observations
keep(*varlist*)	keep specified variables from appending dataset(s)
nolabel	do not copy value-label definitions from dataset(s) on disk
nonotes	do not copy notes from dataset(s) on disk
force	append string to numeric or numeric to string without error

Options

generate(*newvar*) specifies the name of a variable to be created that will mark the source of observations. Observations from the master dataset (the data in memory before the append command) will contain 0 for this variable. Observations from the first using dataset will contain 1 for this variable; observations from the second using dataset will contain 2 for this variable; and so on.

keep(*varlist*) specifies the variables to be kept from the using dataset. If keep() is not specified, all variables are kept.

The *varlist* in keep(*varlist*) differs from standard Stata varlists in two ways: variable names in *varlist* may not be abbreviated, except by the use of wildcard characters, and you may not refer to a range of variables, such as price-weight.

nolabel prevents Stata from copying the value-label definitions from the disk dataset into the dataset in memory. Even if you do not specify this option, label definitions from the disk dataset never replace definitions already in memory.

nonotes prevents notes in the using dataset from being incorporated into the result. The default is to incorporate notes from the using dataset that do not already appear in the master data.

force allows string variables to be appended to numeric variables and vice versa, resulting in missing values from the using dataset. If omitted, append issues an error message; if specified, append issues a warning message.

Remarks and examples   stata.com

The disk dataset must be a Stata-format dataset; that is, it must have been created by save (see [D] **save**).

▷ Example 1

We have two datasets stored on disk that we want to combine. The first dataset, called even.dta, contains the sixth through eighth positive even numbers. The second dataset, called odd.dta, contains the first five positive odd numbers. The datasets are

```
. use even
(6th through 8th even numbers)

. list
```

	number	even
1.	6	12
2.	7	14
3.	8	16

```
. use odd
(First five odd numbers)

. list
```

	number	odd
1.	1	1
2.	2	3
3.	3	5
4.	4	7
5.	5	9

We will append the even data to the end of the odd data. Because the odd data are already in memory (we just used them above), we type `append using even`. The result is

```
. append using even

. list
```

	number	odd	even
1.	1	1	.
2.	2	3	.
3.	3	5	.
4.	4	7	.
5.	5	9	.
6.	6	.	12
7.	7	.	14
8.	8	.	16

Because the `number` variable is in both datasets, the variable was extended with the new data from the file `even.dta`. Because there is no variable called `odd` in the new data, the additional observations on `odd` were forward-filled with *missing* (.). Because there is no variable called `even` in the original data, the first observations on `even` were back-filled with missing.

◁

▷ Example 2

The order of variables in the two datasets is irrelevant. Stata always appends variables by name:

```
. use http://www.stata-press.com/data/r14/odd1
(First five odd numbers)
. describe
Contains data from http://www.stata-press.com/data/r14/odd1.dta
  obs:            5                          First five odd numbers
 vars:            2                          9 Jan 2014 08:41
 size:           40
```

	storage	display	value	
variable name	type	format	label	variable label
odd	float	%9.0g		Odd numbers
number	float	%9.0g		

```
Sorted by: number
. describe using http://www.stata-press.com/data/r14/even
Contains data from http://www.stata-press.com/data/r14/even
  obs:            3                          6th through 8th even numbers
 vars:            2                          9 Jan 2014 08:43
 size:           27
```

	storage	display	value	
variable name	type	format	label	variable label
number	byte	%9.0g		
even	float	%9.0g		Even numbers

```
Sorted by: number
. append using http://www.stata-press.com/data/r14/even
. list
```

	odd	number	even
1.	1	1	.
2.	3	2	.
3.	5	3	.
4.	7	4	.
5.	9	5	.
6.	.	6	12
7.	.	7	14
8.	.	8	16

The results are the same as those in the first example.

◁

When Stata appends two datasets, the definitions of the dataset in memory, called the *master* dataset, override the definitions of the dataset on disk, called the *using* dataset. This extends to value labels, variable labels, characteristics, and date–time stamps. If there are conflicts in numeric storage types, the more precise storage type will be used regardless of whether this storage type was in the *master* dataset or the *using* dataset. If a variable is stored as a string in one dataset that is longer than in the other, the longer str# storage type will prevail. If a variable is stored as a strL in one dataset and a str# in another dataset, the strL storage type will prevail.

❑ Technical note

If a variable is a string in one dataset and numeric in the other, Stata issues an error message unless the `force` option is specified. If `force` is specified, Stata issues a warning message before appending the data. If the using dataset contains the string variable, the combined dataset will have numeric missing values for the appended data on this variable; the contents of the string variable in the using dataset are ignored. If the using dataset contains the numeric variable, the combined dataset will have empty strings for the appended data on this variable; the contents of the numeric variable in the using dataset are ignored.

❑

▷ Example 3

Because Stata has five numeric variable types—`byte`, `int`, `long`, `float`, and `double`—you may attempt to append datasets containing variables with the same name but of different numeric types; see [U] **12.2.2 Numeric storage types**.

Let's `describe` the datasets in the example above:

```
. describe using http://www.stata-press.com/data/r14/odd

Contains data from http://www.stata-press.com/data/r14/odd
  obs:            5                          First five odd numbers
  vars:           2                          9 Jan 2014 08:50
  size:          60
```

| | storage | display | value | |
variable name	type	format	label	variable label
number	float	%9.0g		
odd	float	%9.0g		Odd numbers

```
Sorted by:
. describe using http://www.stata-press.com/data/r14/even

Contains data from http://www.stata-press.com/data/r14/even
  obs:            3                          6th through 8th even numbers
  vars:           2                          9 Jan 2014 08:43
  size:          27
```

| | storage | display | value | |
variable name	type	format	label	variable label
number	byte	%9.0g		
even	float	%9.0g		Even numbers

```
Sorted by: number
. describe using http://www.stata-press.com/data/r14/oddeven

Contains data from http://www.stata-press.com/data/r14/oddeven
  obs:            8                          First five odd numbers
  vars:           3                          9 Jan 2014 08:53
  size:         128
```

| | storage | display | value | |
variable name	type	format	label	variable label
number	float	%9.0g		
odd	float	%9.0g		Odd numbers
even	float	%9.0g		Even numbers

```
Sorted by:
```

The `number` variable was stored as a `float` in `odd.dta` but as a `byte` in `even.dta`. Because `float` is the more precise storage type, the resulting dataset, `oddeven.dta`, had `number` stored as a `float`. Had we instead appended `odd.dta` to `even.dta`, `number` would still have been stored as a `float`:

```
. use http://www.stata-press.com/data/r14/even, clear
(6th through 8th even numbers)

. append using http://www.stata-press.com/data/r14/odd
(note: variable number was byte, now float to accommodate using data's values)

. describe

Contains data from http://www.stata-press.com/data/r14/even.dta
  obs:            8                          6th through 8th even numbers
  vars:           3                          9 Jan 2014 08:43
  size:          96
```

variable name	storage type	display format	value label	variable label
number	float	%9.0g		
even	float	%9.0g		Even numbers
odd	float	%9.0g		Odd numbers

```
Sorted by:
     Note: Dataset has changed since last saved.
```

◁

▷ Example 4

Suppose that we have a dataset in memory containing the variable `educ`, and we have previously given a `label variable educ "Education Level"` command so that the variable label associated with `educ` is "Education Level". We now `append` a dataset called `newdata.dta`, which also contains a variable named `educ`, except that its variable label is "Ed. Lev". After appending the two datasets, the `educ` variable is still labeled "Education Level". See [U] **12.6.2 Variable labels**.

◁

▷ Example 5

Assume that the values of the `educ` variable are labeled with a value label named `educlbl`. Further assume that in `newdata.dta`, the values of `educ` are also labeled by a value label named `educlbl`. Thus there is one definition of `educlbl` in memory and another (although perhaps equivalent) definition in `newdata.dta`. When you `append` the new data, you will see the following:

```
. append using newdata
label educlbl already defined
```

If one label in memory and another on disk have the same name, `append` warns you of the problem and sticks with the definition currently in memory, ignoring the definition in the disk file.

◁

❑ Technical note

When you append two datasets that both contain definitions of the same value label, the codings may not be equivalent. That is why Stata warns you with a message like "label educlbl already defined". If you do not know that the two value labels are equivalent, you should convert the value-labeled variables into string variables, append the data, and then construct a new coding. decode and encode make this easy:

```
. use newdata, clear
. decode educ, gen(edstr)
. drop educ
. save newdata, replace
. use basedata
. decode educ, gen(edstr)
. drop educ
. append using newdata
. encode edstr, gen(educ)
. drop edstr
```

See [D] **encode**.

You can specify the nolabel option to force append to ignore all the value-label definitions in the incoming file, whether or not there is a conflict. In practice, you will probably never want to do this.

❑

▷ Example 6

Suppose that we have several datasets containing the populations of counties in various states. We can use append to combine these datasets all at once and use the generate() option to create a variable identifying from which dataset each observation originally came.

```
. use http://www.stata-press.com/data/r14/capop
. list
```

	county	pop
1.	Los Angeles	9878554
2.	Orange	2997033
3.	Ventura	798364

```
. append using http://www.stata-press.com/data/r14/ilpop
> http://www.stata-press.com/data/r14/txpop, generate(state)
. label define statelab 0 "CA" 1 "IL" 2 "TX"
. label values state statelab
```

```
. list
```

	county	pop	state
1.	Los Angeles	9878554	CA
2.	Orange	2997033	CA
3.	Ventura	798364	CA
4.	Cook	5285107	IL
5.	DeKalb	103729	IL
6.	Will	673586	IL
7.	Brazos	152415	TX
8.	Johnson	149797	TX
9.	Harris	4011475	TX
