\texttt{first} specifies that the first-step probit estimates of the selection equation be displayed before estimation.

\texttt{noskip} specifies that a full maximum-likelihood model with only a constant for the regression equation be fit. This model is not displayed but is used as the base model to compute a likelihood-ratio test for the model test statistic displayed in the estimation header. By default, the overall model test statistic is an asymptotically equivalent Wald test that all the parameters in the regression equation are zero (except the constant). For many models, this option can substantially increase estimation time.

\texttt{nshazard(newvar)} and \texttt{mills(newvar)} are synonyms; either will create a new variable containing the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills ratio—from the selection equation. The nonselection hazard is computed from the estimated parameters of the selection equation.

\texttt{nocnsreport}; see [R] estimation options.

\texttt{display_options}: \texttt{nci}, \texttt{nopvalues}, \texttt{noomitted}, \texttt{vsquish}, \texttt{noemptycells}, \texttt{baselevels}, \texttt{allbaselevels}, \texttt{nofvlabel}, \texttt{fvwrap(#)}, \texttt{fvwrapon(style)}, \texttt{cformat(\%fmt)}, \texttt{pformat(\%fmt)}, \texttt{sformat(\%fmt)}, and \texttt{nolstretch}; see [R] estimation options.

\texttt{Maximization} \texttt{maximize_options}: \texttt{difficult}, \texttt{technique(algorithm_spec)}, \texttt{iterate(#)}, \texttt{[no]log}, \texttt{trace}, \texttt{gradient}, \texttt{showstep}, \texttt{hessian}, \texttt{showtolerance}, \texttt{tolerance(#)}, \texttt{ltolerance(#)}, \texttt{ntolerance(#)}, \texttt{nonrtolerance}, and \texttt{from(init_specs)}; see [R] \texttt{maximize}. These options are seldom used.

Setting the optimization type to \texttt{technique(bhhh)} resets the default \texttt{vcetype} to \texttt{vce(opg)}.

The following option is available with \texttt{heckman} but is not shown in the dialog box:

\texttt{coeflegend}; see [R] estimation options.
Options for Heckman selection model (two-step)

Model

select([ depvar_s = ] varlist_s [, noconstant ]) specifies the variables and options for the selection equation. It is an integral part of specifying a Heckman model and is required. The selection equation should contain at least one variable that is not in the outcome equation.

If depvar_s is specified, it should be coded as 0 or 1, with 0 indicating an observation not selected and 1 indicating a selected observation. If depvar_s is not specified, observations for which depvar is not missing are assumed selected, and those for which depvar is missing are assumed not selected.

noconstant suppresses the selection constant term (intercept).

twostep specifies that Heckman’s (1979) two-step efficient estimates of the parameters, standard errors, and covariance matrix be produced.

noconstant; see [R] estimation options.

rhosigma, rhotrunc, rholimited, and rhoforce are rarely used options to specify how the two-step estimator (option twostep) handles unusual cases in which the two-step estimate of \( \rho \) is outside the admissible range for a correlation, \([-1, 1]\). When \( \text{abs}(\rho) > 1 \), the two-step estimate of the coefficient variance–covariance matrix may not be positive definite and thus may be unusable for testing. The default is rhosigma.

rhosigma specifies that \( \rho \) be truncated, as with the rhotrunc option, and that the estimate of \( \sigma \) be made consistent with \( \hat{\rho} \), the truncated estimate of \( \rho \). So, \( \hat{\sigma} = \beta_m \hat{\rho} \); see Methods and formulas for the definition of \( \beta_m \). Both the truncated \( \rho \) and the new estimate of \( \hat{\sigma} \) are used in all computations to estimate the two-step covariance matrix.

rhotrunc specifies that \( \rho \) be truncated to lie in the range \([-1, 1]\). If the two-step estimate is less than \(-1\), \( \rho \) is set to \(-1\); if the two-step estimate is greater than \(1\), \( \rho \) is set to \(1\). This truncated value of \( \rho \) is used in all computations to estimate the two-step covariance matrix.

rholimited specifies that \( \rho \) be truncated only in computing the diagonal matrix \( D \) as it enters \( V_{\text{twostep}} \) and \( Q \); see Methods and formulas. In all other computations, the untruncated estimate of \( \rho \) is used.

rhoforce specifies that the two-step estimate of \( \rho \) be retained, even if it is outside the admissible range for a correlation. This option may, in rare cases, lead to a non–positive-definite covariance matrix.

These options have no effect when estimation is by maximum likelihood, the default. They also have no effect when the two-step estimate of \( \rho \) is in the range \([-1, 1]\).

SE

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (conventional) and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

vce(conventional), the default, uses the two-step variance estimator derived by Heckman.

level(#) ; see [R] estimation options.

first specifies that the first-step probit estimates of the selection equation be displayed before estimation.
`nshazard(newvar)` and `mills(newvar)` are synonyms; either will create a new variable containing the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills ratio—from the selection equation. The nonselection hazard is computed from the estimated parameters of the selection equation.

The following option is available with `heckman` but is not shown in the dialog box: `coeflegend`; see [R] estimation options.

**Remarks and examples**

The Heckman selection model (Gronau 1974; Lewis 1974; Heckman 1976) assumes that there exists an underlying regression relationship,

\[ y_j = x_j \beta + u_{1j} \]

**regression equation**

The dependent variable, however, is not always observed. Rather, the dependent variable for observation \( j \) is observed if

\[ z_j \gamma + u_{2j} > 0 \]

**selection equation**

where

- \( u_1 \sim N(0, \sigma) \)
- \( u_2 \sim N(0, 1) \)
- \( \text{corr}(u_1, u_2) = \rho \)

When \( \rho \neq 0 \), standard regression techniques applied to the first equation yield biased results. `heckman` provides consistent, asymptotically efficient estimates for all the parameters in such models.

In one classic example, the first equation describes the wages of women. Women choose whether to work, and thus, from our point of view as researchers, whether we observe their wages in our data. If women made this decision randomly, we could ignore that not all wages are observed and use ordinary regression to fit a wage model. Such an assumption of random participation, however, is unlikely to be true; women who would have low wages may be unlikely to choose to work, and thus the sample of observed wages is biased upward. In the jargon of economics, women choose not to work when their personal reservation wage is greater than the wage offered by employers. Thus women who choose not to work might have even higher offer wages than those who do work—they may have high offer wages, but they have even higher reservation wages. We could tell a story that competency is related to wages, but competency is rewarded more at home than in the labor force.

In any case, in this problem—which is the paradigm for most such problems—a solution can be found if there are some variables that strongly affect the chances for observation (the reservation wage) but not the outcome under study (the offer wage). Such a variable might be the number of children in the home. (Theoretically, we do not need such identifying variables, but without them, we depend on functional form to identify the model. It would be difficult for anyone to take such results seriously because the functional form assumptions have no firm basis in theory.)
Example 1

In the syntax for `heckman`, `depvar` and `indepvars` are the dependent variable and regressors for the underlying regression model to be fit \((y = X\beta)\), and `varlist`s are the variables \((Z)\) thought to determine whether `depvar` is observed or unobserved (selected or not selected). In our female wage example, the number of children at home would be included in the second list. By default, `heckman` assumes that missing values (see \[U] 12.2.1 Missing values) of `depvar` imply that the dependent variable is unobserved (not selected). With some datasets, it is more convenient to specify a binary variable \((depvars)=0)\) that identifies the observations for which the dependent is observed/selected \((depvars \neq 0)\); `heckman` will accommodate either type of data. Here we have a (fictional) dataset on 2,000 women, 1,343 of whom work:

```
use http://www.stata-press.com/data/r14/womenwk
summarize age educ married children wage
```

</table>

We will assume that the hourly wage is a function of education and age, whereas the likelihood of working (the likelihood of the wage being observed) is a function of marital status, the number of children at home, and (implicitly) the wage (via the inclusion of age and education, which we think determine the wage):

```

heckman assumes that wage is the dependent variable and that the first variable list (educ and age) are the determinants of wage. The variables specified in the select() option (married, children, educ, and age) are assumed to determine whether the dependent variable is observed (the selection equation). Thus we fit the model

$$\text{wage} = \beta_0 + \beta_1\text{educ} + \beta_2\text{age} + \nu_1$$

and we assumed that wage is observed if

$$\gamma_0 + \gamma_1\text{married} + \gamma_2\text{children} + \gamma_3\text{educ} + \gamma_4\text{age} + \nu_2 > 0$$

where $\nu_1$ and $\nu_2$ have correlation $\rho$.

The reported results for the wage equation are interpreted exactly as though we observed wage data for all women in the sample; the coefficients on age and education level represent the estimated marginal effects of the regressors in the underlying regression equation. The results for the two ancillary parameters require some explanation. heckman does not directly estimate $\rho$; to constrain $\rho$ within its valid limits, and for numerical stability during optimization, it estimates the inverse hyperbolic tangent of $\rho$: 

$$\text{atanh} \, \rho = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right)$$

This estimate is reported as `/athrho`. In the bottom panel of the output, heckman undoes this transformation for you: the estimated value of $\rho$ is 0.7035061. The standard error for $\rho$ is computed using the delta method, and its confidence intervals are the transformed intervals of `/athrho`.

Similarly, $\sigma$, the standard error of the residual in the wage equation, is not directly estimated; for numerical stability, heckman instead estimates $\ln \sigma$. The untransformed sigma is reported at the end of the output: 6.004797.

Finally, some researchers—especially economists—are used to the selectivity effect summarized not by $\rho$ but by $\lambda = \rho \sigma$. heckman reports this, too, along with an estimate of the standard error and confidence interval.

Technical note

If each of the equations in the model had contained many regressors, the heckman command could have become long. An alternate way of specifying our wage model would be to use Stata’s global macros. The following lines are an equivalent way of specifying our model:

```
. global wageeq "wage educ age"
. global seleq "married children educ age"
. heckman $wageeq, select($seleq)
```

Technical note

The reported model $\chi^2$ test is a Wald test that all coefficients in the regression model (except the constant) are 0. heckman is an estimation command, so you can use test, testnl, or lrtest to perform tests against whatever nested alternate model you choose; see [R] test, [R] testnl, and [R] lrtest.
The estimation of $\rho$ and $\sigma$ in the forms $\text{atanh} \rho$ and $\ln \sigma$ extends the range of these parameters to infinity in both directions, thus avoiding boundary problems during the maximization. Tests of $\rho$ must be made in the transformed units. However, because $\text{atanh}(0) = 0$, the reported test for $\text{atanh} \rho = 0$ is equivalent to the test for $\rho = 0$.

The likelihood-ratio test reported at the bottom of the output is an equivalent test for $\rho = 0$ and is computationally the comparison of the joint likelihood of an independent probit model for the selection equation and a regression model on the observed wage data against the Heckman model likelihood. Because $\chi^2 = 61.20$, this clearly justifies the Heckman selection equation with these data.

Example 2

`heckman` supports the Huber/White/sandwich estimator of variance under the `vce(robust)` and `vce(cluster clustvar)` options or when `pweights` are used for population-weighted data; see [U] 20.21 Obtaining robust variance estimates. We can obtain robust standard errors for our wage model by specifying clustering on county of residence (the county variable).

```
. heckman wage educ age, select(married children educ age) vce(cluster county)
Iteration 0: log pseudolikelihood = -5178.7009
Iteration 1: log pseudolikelihood = -5178.3049
Iteration 2: log pseudolikelihood = -5178.3045
Heckman selection model Number of obs = 2,000
(regression model with sample selection) Censored obs = 657
Uncensored obs = 1,343
Wald chi2(1) = .
(Std. Err. adjusted for 10 clusters in county)

| _cons    | .7035061 | .0708796 | .53   | 0.594 | .6078199  .8092726 |
| sigma    | 6.004797 | .155199  | 6.31  | 0.000 | 5.708189  6.316818 |
| lambda   | 4.224412 | .5186709 | 8.17  | 0.000 | 3.207835  5.240988 |
```

The robust standard errors tend to be a bit larger, but we notice no systematic differences. This finding is not surprising because the data were not constructed to have any county-specific correlations or any other characteristics that would deviate from the assumptions of the Heckman model.
Example 3

Stata also produces Heckman’s (1979) two-step efficient estimator of the model with the `twostep` option. Maximum likelihood estimation of the parameters can be time consuming with large datasets, and the two-step estimates may provide a good alternative in such cases. Continuing with the women’s wage model, we can obtain the two-step estimates with Heckman’s consistent covariance estimates by typing

```
. heckman wage educ age, select(married children educ age) twostep
```

Technical note

The Heckman selection model depends strongly on the model being correct, much more so than ordinary regression. Running a separate probit or logit for sample inclusion followed by a regression, referred to in the literature as the two-part model (Manning, Duan, and Rogers 1987)—not to be confused with Heckman’s two-step procedure—is an especially attractive alternative if the regression part of the model arose because of taking a logarithm of zero values. When the goal is to analyze an underlying regression model or to predict the value of the dependent variable that would be observed in the absence of selection, however, the Heckman model is more appropriate. When the goal is to predict an actual response, the two-part model is usually the better choice.

The Heckman selection model can be unstable when the model is not properly specified or if a specific dataset simply does not support the model’s assumptions. For example, let’s examine the solution to another simulated problem.
. use http://www.stata-press.com/data/r14/twopart

LR test of indep. eqns. (rho = 0): chi2(1) = 25.67 Prob > chi2 = 0.0000

The model has converged to a value of \( \rho \) that is 1.0—within machine-rounding tolerances. Given the form of the likelihood for the Heckman selection model, this implies a division by zero, and it is surprising that the model solution turns out as well as it does. Reparameterizing \( \rho \) has allowed the estimation to converge, but we clearly have problems with the estimates. Moreover, if this had occurred in a large dataset, waiting for convergence might take considerable time.

This dataset was not intentionally developed to cause problems. It is actually generated by a “Heckman process” and when generated starting from different random values can be easily estimated. The luck of the draw here merely led to data that, despite the source, did not support the assumptions of the Heckman model.

The two-step model is generally more stable when the data are problematic. It even tolerates estimates of \( \rho \) less than \(-1\) and greater than 1. For these reasons, the two-step model may be preferred when exploring a large dataset. Still, if the maximum likelihood estimates cannot converge, or converge to a value of \( \rho \) that is at the boundary of acceptable values, there is scant support for fitting a Heckman selection model on the data. Heckman (1979) discusses the implications of \( \rho \) being exactly 1 or 0, together with the implications of other possible covariance relationships among the model’s determinants.
Stored results

heckman (maximum likelihood) stores the following in e():

Scalars

- **e(N)**: number of observations
- **e(N_cens)**: number of censored observations
- **e(k)**: number of parameters
- **e(k_eq)**: number of equations in e(b)
- **e(k_eq_model)**: number of equations in overall model test
- **e(k_aux)**: number of auxiliary parameters
- **e(k_dv)**: number of dependent variables
- **e(df_m)**: model degrees of freedom
- **e(ll)**: log likelihood
- **e(ll0)**: log likelihood, constant-only model
- **e(N_clust)**: number of clusters
- **e(lambda)**: \( \lambda \)
- **e(selambda)**: standard error of \( \lambda \)
- **e(sigma)**: \( \sigma \)
- **e(chi2)**: \( \chi^2 \)
- **e(chi2_c)**: \( \chi^2 \) for comparison test
- **e(p_c)**: \( p \) for comparison test
- **e(p)**: significance of comparison test
- **e(rho)**: \( \rho \)
- **e(rank)**: rank of e(V)
- **e(rank0)**: rank of e(V) for constant-only model
- **e(ic)**: number of iterations
- **e(rc)**: return code
- **e(converged)**: 1 if converged, 0 otherwise

Macros

- **e(cmd)**: heckman
- **e(cmdline)**: command as typed
- **e(depvar)**: names of dependent variables
- **e(wtype)**: weight type
- **e(wexp)**: weight expression
- **e(title)**: title in estimation output

- **e(vcetype)**: title used to label Std. Err.
- **e(opt)**: type of optimization
- **e(which)**: max or min; whether optimizer is to perform maximization or minimization
- **e(method)**: ml
- **e(ml_method)**: type of ml method
- **e(user)**: name of likelihood-evaluator program
- **e(technique)**: maximization technique
- **e(properties)**: b V
- **e(predict)**: program used to implement predict
- **e(marginsok)**: predictions allowed by margins
- **e(asbalanced)**: factor variables fvset as asbalanced
- **e(asobserved)**: factor variables fvset as asobserved

Matrices

- **e(b)**: coefficient vector
- **e(Cns)**: constraints matrix
- **e(11og)**: iteration log (up to 20 iterations)
- **e(gradient)**: gradient vector
- **e(V)**: variance–covariance matrix of the estimators
- **e(V_modelbased)**: model-based variance
Functions
e(sample) marks estimation sample

heckman (two-step) stores the following in e():

Scalars
e(N) number of observations
e(N_cens) number of censored observations
e(df_m) model degrees of freedom
e(lambda) \( \lambda \)
e(selambda) standard error of \( \lambda \)
e(sigma) \( \sigma \)
e(chi2) \( \chi^2 \)
e(p) significance of comparison test
e(rho) \( \rho \)
e(rank) rank of e(V)

Macros
e(cmd) heckman
 e(cmdline) command as typed
 e(depvar) names of dependent variables
 e(title) title in estimation output
 e(title2) secondary title in estimation output
 e(mills) variable containing nonselection hazard (inverse of Mills’s ratio)
e(chi2type) Wald or LR; type of model \( \chi^2 \) test
 e(vce) vcetype specified in vce()
e(vcetype) title used to label Std. Err.
e(rhometh) rhosigma, rotrunc, rholimited, or rhoforce
 e(method) twostep
 e(properties) b V
 e(predict) program used to implement predict
 e(marginsok) predictions allowed by margins
 e(marginsnotok) predictions disallowed by margins
 e(asbalanced) factor variables fvset as asbalanced
 e(asobserved) factor variables fvset as asobserved

Matrices
e(b) coefficient vector
e(Cns) constraints matrix
e(V) variance–covariance matrix of the estimators

Functions
e(sample) marks estimation sample

James Joseph Heckman was born in Chicago in 1944 and studied mathematics at Colorado College and economics at Princeton. He has taught economics at Columbia and (since 1973) at the University of Chicago. He has worked on developing a scientific basis for economic policy evaluation, with emphasis on models of individuals or disaggregated groups and the problems and possibilities created by heterogeneity, diversity, and unobserved counterfactual states. In 2000, he shared the Nobel Prize in Economics with Daniel L. McFadden.

Methods and formulas

 Regression estimates using the nonselection hazard (Heckman 1979) provide starting values for maximum likelihood estimation.

The regression equation is
\[ y_j = x_j \beta + u_{1j} \]

The selection equation is
\[ z_j \gamma + u_{2j} > 0 \]

where
\[ u_1 \sim N(0, \sigma) \]
\[ u_2 \sim N(0, 1) \]
\[ \text{corr}(u_1, u_2) = \rho \]

The log likelihood for observation \( j \), \( \ln L_j = l_j \), is
\[
l_j = \begin{cases} 
  w_j \ln \Phi \left\{ z_j \gamma + \frac{(y_j - x_j \beta) \rho / \sigma}{\sqrt{1 - \rho^2}} \right\} - \frac{w_j}{2} \left( \frac{y_j - x_j \beta}{\sigma} \right)^2 - w_j \ln(2 \pi \sigma) & \text{\( y_j \) observed} \\
  w_j \ln \Phi(-z_j \gamma) & \text{\( y_j \) not observed}
\end{cases}
\]

where \( \Phi(\cdot) \) is the standard cumulative normal and \( w_j \) is an optional weight for observation \( j \).

In the maximum likelihood estimation, \( \sigma \) and \( \rho \) are not directly estimated. Directly estimated are \( \ln(\sigma) \) and \( \text{atanh}(\rho) \):
\[ \text{atanh}(\rho) = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right) \]

The standard error of \( \lambda = \rho \sigma \) is approximated through the propagation of error (delta) method; that is,
\[ \text{Var}(\lambda) \approx D \text{Var}\{ \text{atanh}(\rho) \ln(\sigma) \} D' \]

where \( D \) is the Jacobian of \( \lambda \) with respect to \( \text{atanh}(\rho) \) and \( \ln(\sigma) \).

With maximum likelihood estimation, this command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See [P] \_robust, particularly \textit{Maximum likelihood estimators} and \textit{Methods and formulas}.

The maximum likelihood version of heckman also supports estimation with survey data. For details on VCEs with survey data, see [SVY] variance estimation.

The two-step estimates are computed using Heckman’s (1979) procedure.

Probit estimates of the selection equation
\[ \Pr(y_j \text{ observed} \mid z_j) = \Phi(z_j \gamma) \]

are obtained. From these estimates, the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills ratio, \( m_j \)—for each observation \( j \) is computed as
\[ m_j = \frac{\phi(z_j \tilde{\gamma})}{\Phi(z_j \tilde{\gamma})} \]
where $\phi$ is the normal density. We also define

$$\delta_j = m_j(m_j + \hat{\gamma} z_j)$$

Following Heckman, the two-step parameter estimates of $\beta$ are obtained by augmenting the regression equation with the nonselection hazard $m$. Thus the regressors become $[X \ m]$, and we obtain the additional parameter estimate $\beta_m$ on the variable containing the nonselection hazard.

A consistent estimate of the regression disturbance variance is obtained using the residuals from the augmented regression and the parameter estimate on the nonselection hazard,

$$\hat{\sigma}^2 = \mathbf{e}'\mathbf{e} + \beta_m^2 \sum_{j=1}^{N} \delta_j$$

The two-step estimate of $\rho$ is then

$$\hat{\rho} = \frac{\beta_m}{\hat{\sigma}}$$

Heckman derived consistent estimates of the coefficient covariance matrix on the basis of the augmented regression.

Let $W = [X \ m]$ and $R$ be a square, diagonal matrix of dimension $N$, with $(1 - \hat{\rho}^2 \delta_j)$ as the diagonal elements. The conventional VCE is

$$V_{\text{twostep}} = \hat{\sigma}^2 (W'W)^{-1}(W'RW + Q)(W'W)^{-1}$$

where

$$Q = \hat{\rho}^2 (W'DZ)V_p(Z'DW)$$

where $D$ is the square, diagonal matrix of dimension $N$ with $\delta_j$ as the diagonal elements; $Z$ is the data matrix of selection equation covariates; and $V_p$ is the variance–covariance estimate from the probit estimation of the selection equation.

</tbody>
</table>

These statistics are available both in and out of sample; type \text{predict ... if e(sample)} ... if wanted only for the estimation sample.

\( \text{stdf} \) is not allowed with \text{svy} estimation results.

where \( a \) and \( b \) may be numbers or variables; \( a \text{ missing (}a \geq .\text{) means } -\infty \), and \( b \text{ missing (}b \geq .\text{) means } +\infty \); see [U] 12.2.1 Missing values.
Options for predict

xb, the default, calculates the linear prediction $x_j b$.

stdp calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation’s covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

stdf calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value.

stdp calculates the standard error of the linear prediction for the selection equation.

stdpsel calculates the standard error of the linear prediction for the selection equation.

pr($a,b$) calculates $Pr(a < x_j b + u_1 < b)$, the probability that $y_j \mid x_j$ would be observed in the interval $(a,b)$.

$a$ and $b$ may be specified as numbers or variable names; $lb$ and $ub$ are variable names;

pr($20,30$) calculates $Pr(20 < x_j b + u_1 < 30)$; $pr(lb,ub)$ calculates $Pr(lb < x_j b + u_1 < ub)$; and $pr(20,ub)$ calculates $Pr(20 < x_j b + u_1 < ub)$.

$a$ missing ($a \geq$.) means $-\infty$; $pr(.,30)$ calculates $Pr(-\infty < x_j b + u_1 < 30)$;

$pr(lb,30)$ calculates $Pr(-\infty < x_j b + u_1 < 30)$ in observations for which $lb \geq$.

and calculates $Pr(lb < x_j b + u_1 < 30)$ elsewhere.

$b$ missing ($b \geq$.) means $+\infty$; $pr(20,.)$ calculates $Pr(+\infty > x_j b + u_1 > 20)$;

$pr(20,ub)$ calculates $Pr(+\infty > x_j b + u_1 > 20)$ in observations for which $ub \geq$.

and calculates $Pr(20 < x_j b + u_1 < ub)$ elsewhere.

e($a,b$) calculates $E(x_j b + u_1 \mid a < x_j b + u_1 < b)$, the expected value of $y_j \mid x_j$ conditional on $y_j \mid x_j$ being in the interval $(a,b)$, meaning that $y_j \mid x_j$ is truncated.

$a$ and $b$ are specified as they are for pr().

ystar($a,b$) calculates $E(y_j^* \mid a < x_j b + u_1 < b)$, where $y_j^* = a$ if $x_j b + u_1 \leq a$, $y_j^* = b$ if $x_j b + u_1 \geq b$, and $y_j^* = x_j b + u_1$ otherwise, meaning that $y_j^*$ is censored. $a$ and $b$ are specified as they are for pr().

ycond calculates the expected value of the dependent variable conditional on the dependent variable being observed, that is, selected; $E(y_j \mid y_j$ observed).

yexpected calculates the expected value of the dependent variable ($y_j^*$), where that value is taken to be 0 when it is expected to be unobserved; $y_j^* = Pr(y_j$ observed)$E(y_j \mid y_j$ observed).

The assumption of 0 is valid for many cases where nonselection implies nonparticipation (for example, unobserved wage levels, insurance claims from those who are uninsured) but may be inappropriate for some problems (for example, unobserved disease incidence).

nshazard and mills are synonyms; both calculate the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills ratio—from the selection equation.

psel calculates the probability of selection (or being observed): $Pr(y_j$ observed) = $Pr(z_j \gamma + u_{2j} > 0)$.

nooffset is relevant when you specify offset(varname) for heckman. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $x_j b$ rather than as $x_j b + offset_j$. 

Methods and formulas

Main

xb, the default, calculates the linear prediction $x_j b$.

stdp calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation’s covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

stdf calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value.

By construction, the standard errors produced by stdf are always larger than those produced by stdp; see Methods and formulas in [R] regress postestimation.

xbselect calculates the linear prediction for the selection equation.

stddp calculates the standard error of the linear prediction for the selection equation.

pr($a,b$) calculates $Pr(a < x_j b + u_1 < b)$, the probability that $y_j \mid x_j$ would be observed in the interval $(a,b)$.

$a$ and $b$ may be specified as numbers or variable names; $lb$ and $ub$ are variable names;

pr($20,30$) calculates $Pr(20 < x_j b + u_1 < 30)$; $pr(lb,ub)$ calculates $Pr(lb < x_j b + u_1 < ub)$; and $pr(20,ub)$ calculates $Pr(20 < x_j b + u_1 < ub)$.

$a$ missing ($a \geq$.) means $-\infty$; $pr(.,30)$ calculates $Pr(-\infty < x_j b + u_1 < 30)$;

$pr(lb,30)$ calculates $Pr(-\infty < x_j b + u_1 < 30)$ in observations for which $lb \geq$.

and calculates $Pr(lb < x_j b + u_1 < 30)$ elsewhere.

$b$ missing ($b \geq$.) means $+\infty$; $pr(20,.)$ calculates $Pr(+\infty > x_j b + u_1 > 20)$;

$pr(20,ub)$ calculates $Pr(+\infty > x_j b + u_1 > 20)$ in observations for which $ub \geq$.

and calculates $Pr(20 < x_j b + u_1 < ub)$ elsewhere.

e($a,b$) calculates $E(x_j b + u_1 \mid a < x_j b + u_1 < b)$, the expected value of $y_j \mid x_j$ conditional on $y_j \mid x_j$ being in the interval $(a,b)$, meaning that $y_j \mid x_j$ is truncated.

$a$ and $b$ are specified as they are for pr().

ystar($a,b$) calculates $E(y_j^* \mid a < x_j b + u_1 < b)$, where $y_j^* = a$ if $x_j b + u_1 \leq a$, $y_j^* = b$ if $x_j b + u_1 \geq b$, and $y_j^* = x_j b + u_1$ otherwise, meaning that $y_j^*$ is censored. $a$ and $b$ are specified as they are for pr().

ycond calculates the expected value of the dependent variable conditional on the dependent variable being observed, that is, selected; $E(y_j \mid y_j$ observed).

yexpected calculates the expected value of the dependent variable ($y_j^*$), where that value is taken to be 0 when it is expected to be unobserved; $y_j^* = Pr(y_j$ observed)$E(y_j \mid y_j$ observed).

The assumption of 0 is valid for many cases where nonselection implies nonparticipation (for example, unobserved wage levels, insurance claims from those who are uninsured) but may be inappropriate for some problems (for example, unobserved disease incidence).

nshazard and mills are synonyms; both calculate the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills ratio—from the selection equation.

psel calculates the probability of selection (or being observed): $Pr(y_j$ observed) = $Pr(z_j \gamma + u_{2j} > 0)$.

nooffset is relevant when you specify offset(varname) for heckman. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $x_j b$ rather than as $x_j b + offset_j$. 

Methods and formulas

Main
scores, not available with `twostep`, calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial (x_j \beta)$.

The second new variable will contain $\partial \ln L / \partial (z_j \gamma)$.

The third new variable will contain $\partial \ln L / \partial (\text{atanh } \rho)$.

The fourth new variable will contain $\partial \ln L / \partial (\ln \sigma)$.

**margins**

**Description for margins**

`margins` estimates margins of response for linear predictions, probabilities, expected values, and nonselection hazards.

**Menu for margins**

</table>

Statistics not allowed with `margins` are functions of stochastic quantities other than $e(b)$.

For the full syntax, see [R] `margins`. 
Remarks and examples

Example 1

The default statistic produced by `predict` after `heckman` is the expected value of the dependent variable from the underlying distribution of the regression model. In the wage model of [R] `heckman`, this is the expected wage rate among all women, regardless of whether they were observed to participate in the labor force:

```
use http://www.stata-press.com/data/r14/womenwk
. heckman wage educ age, select(married children educ age) vce(cluster county)  
(output omitted)
. predict heckwage (option `xb' assumed; fitted values)
```

It is instructive to compare these predicted wage values from the Heckman model with an ordinary regression model—a model without the selection adjustment:

```
. regress wage educ age

Source         SS       df       MS           Number of obs = 1,343
Model    13524.0337     2  6762.01687      F(2, 1340) = 227.49
           Residual   39830.8609   1,340  29.7245231     Prob > F = 0.0000
           Total     53354.8946   1,342  39.7577456     R-squared = 0.2535
Adj R-squared = 0.2524

         wage    Coef.  Std. Err.     t     P>|t|    [95% Conf. Interval]
------------- -------- -------- -------- -------- ------------------
education    .8965829  .0498061   18.00   0.000    .7988765 -.9942893
age         .1465739  .0187135    7.83   0.000    .109863  .1832848
_cons        6.084875  .8896182    6.84   0.000    4.339679  7.830071
```

```
. predict regwage (option `xb' assumed; fitted values)
. summarize heckwage regwage

Variable         Obs  Mean    Std. Dev.    Min     Max
------------- -------- -------- -------- -------- --------
heckwage       2,000  21.15532   3.83965  14.6479  32.85949
regwage         2,000  23.12291   3.241911 17.98218 32.66439
```

Since this dataset was concocted, we know the true coefficients of the wage regression equation to be 1, 0.2, and 1, respectively. We can compute the true mean wage for our sample.

```
. generate truewage = 1 + .2*age + 1*educ
. summarize truewage

Variable         Obs  Mean    Std. Dev.    Min     Max
------------- -------- -------- -------- -------- --------
truewage        2,000  21.3256   3.797904    15     32.8
```

Whereas the mean of the predictions from `heckman` is within 18 cents of the true mean wage, ordinary regression yields predictions that are on average about $1.80 per hour too high because of the selection effect. The regression predictions also show somewhat less variation than the true wages.

The coefficients from `heckman` are so close to the true values that they are not worth testing. Conversely, the regression equation is significantly off but seems to give the right sense. Would we be led far astray if we relied on the OLS coefficients? The effect of age is off by more than 5 cents per year of age, and the coefficient on education level is off by about 10%. We can test the OLS coefficient on education level against the true value by using `test`.
Not only is the OLS coefficient on education substantially lower than the true parameter, but the difference from the true parameter is also statistically significant beyond the 5% level. We can perform a similar test for the OLS age coefficient:

```
. test age = .2
   ( 1) age = .2
   F( 1, 1340) = 8.15
   Prob > F = 0.0044
```

We find even stronger evidence that the OLS regression results are biased away from the true parameters.

### Example 2

Several other interesting aspects of the Heckman model can be explored with `predict`. Continuing with our wage model, we can obtain the expected wages for women conditional on participating in the labor force with the `ycond` option. Let’s get these predictions and compare them with actual wages for women participating in the labor force.

```stata
. use http://www.stata-press.com/data/r14/womenwk, clear
. heckman wage educ age, select(married children educ age)  
   (output omitted)
. predict hcondwage, ycond
. summarize wage hcondwage if wage != .
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>wage</td>
<td>1,343</td>
<td>23.6922</td>
<td>6.305374</td>
<td>5.88497</td>
<td>45.80979</td>
</tr>
<tr>
<td>hcondwage</td>
<td>1,343</td>
<td>23.68239</td>
<td>3.335087</td>
<td>16.18337</td>
<td>33.7567</td>
</tr>
</tbody>
</table>

We see that the average predictions from `heckman` are close to the observed levels but do not have the same mean. These conditional wage predictions are available for all observations in the dataset but can be directly compared only with observed wages, where individuals are participating in the labor force.

What if we were interested in making predictions about mean wages for all women? Here the expected wage is 0 for those who are not expected to participate in the labor force, with expected participation determined by the selection equation. These values can be obtained with the `yexpected` option of `predict`. For comparison, a variable can be generated where the wage is set to 0 for nonparticipants.

```stata
. predict hexpwage, yexpected
. generate wage0 = wage
   (657 missing values generated)
. replace wage0 = 0 if wage == .
   (657 real changes made)
```
Again we note that the predictions from \texttt{heckman} are close to the observed mean hourly wage rate for all women. Why aren't the predictions using \texttt{ycond} and \texttt{yexpected} equal to their observed sample equivalents? For the Heckman model, unlike linear regression, the sample moments implied by the optimal solution to the model likelihood do not require that these predictions match observed data. Properly accounting for the additional variation from the selection equation requires that the model use more information than just the sample moments of the observed wages.

[R] \texttt{heckman} — Heckman selection model

[U] 20 Estimation and postestimation commands
heckoprobit — Ordered probit model with sample selection

Description

heckoprobit fits maximum-likelihood ordered probit models with sample selection.

Quick start

Ordered probit model of \( y \) on \( x \) with selection indicated by binary variable \( \text{selected} \) and predicted by \( v \)

\[ \text{heckoprobit} \ y \ x, \ select(\text{selected} = v \ x) \]

Add indicator variables for each level of categorical variable \( a \)

\[ \text{heckoprobit} \ y \ x \ i.a, \ select(\text{selected} = v \ x \ i.a) \]

Account for complex sampling design using \texttt{svyset} data

\[ \text{svy: heckoprobit} \ y \ x, \ select(\text{selected} = v \ x) \]

Menu

Statistics > Sample-selection models > Ordered probit model with selection
## Syntax

```plaintext
heckoprobit depvar indepvars [if] [in] [weight],
    select([depvar_s =] varlist_s [, noconstant offset(varname_o)]) [options]
```

### Model

- `select()`
  - Specifies the variables and options for the selection equation. It is an integral part of specifying a selection model and is required. The selection equation should contain at least one variable that is not in the outcome equation.

- `offset(varname)`
  - Include `varname` in model with coefficient constrained to 1

- `constraints(constants)`
  - Apply specified linear constraints

- `collinear`
  - Keep collinear variables

### SE/Robust

- `vce(vcetype)`
  - `vcetype` may be `oim`, `robust`, `cluster clustvar`, `opg`, `bootstrap`, or `jackknife`

### Reporting

- `level(#)`
  - Set confidence level; default is `level(95)`

- `first`
  - Report first-step probit estimates

- `noheader`
  - Do not display header above parameter table

- `nofootnote`
  - Do not display footnotes below parameter table

- `noconsreport`
  - Do not display constraints

- `display_options`
  - Control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

### Maximization

- `maximize_options`
  - Control the maximization process; seldom used

- `coeflegend`
  - Display legend instead of statistics

*`select()` is required.

The full specification is `select([depvar_s =] varlist_s [, noconstant offset(varname_o)])`.

### Options

- `indepvars` and `varlist_s` may contain factor variables; see [U] 11.4.3 Factor variables.
- `depvar`, `indepvars`, `depvar_s`, and `varlist_s` may contain time-series operators; see [U] 11.4.4 Time-series varlists.
- `bootstrap`, `by`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands.
- Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.
- `vce()`, `first`, and weights are not allowed with the `svy` prefix; see [SVY] svy.
- `pweight`, `fweight`, and `iweight` are allowed; see [U] 11.1.6 weight.
- `coeflegend` does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
If $\text{depvar}_s$ is specified, it should be coded as 0 or 1, 0 indicating an observation not selected and 1 indicating a selected observation. If $\text{depvar}_s$ is not specified, observations for which $\text{depvar}$ is not missing are assumed selected, and those for which $\text{depvar}$ is missing are assumed not selected.

`noconstant` suppresses the selection constant term (intercept).

`offset(varname_o)` specifies that selection offset $\text{varname}_o$ be included in the model with the coefficient constrained to be 1.

`offset(varname), constraints(constraints), collinear`; see [R] estimation options.

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] vce_option.

`level(#);` see [R] estimation options.

`first` specifies that the first-step probit estimates of the selection equation be displayed before estimation.

`noheader` suppresses the header above the parameter table, the display that reports the final log-likelihood value, number of observations, etc.

`nofootnote` suppresses the footnotes displayed below the parameter table.

`nocnsreport`; see [R] estimation options.

`display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels,nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch;` see [R] estimation options.

`maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs);` see [R] maximize. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg).

The following option is available with `heckoprobit` but is not shown in the dialog box:

`coeflegend;` see [R] estimation options.

Remarks and examples

`heckoprobit` estimates the parameters of a regression model for an ordered categorical outcome from a nonrandom sample known as a selected sample. Selected samples suffer from “selection on unobservables” because the errors that determine whether a case is missing are correlated with the errors that determine the outcome.

For ordered categorical regression from samples that do not suffer from selection on unobservables, see [R] `oprobit` or [R] `ologit`. For regression of a continuous outcome variable from a selected sample, see [R] `heckman`.
Even though we are interested in modeling a single ordinal outcome, there are two dependent variables in the ordered probit sample-selection model because we must also model the sample-selection process. First, there is the ordinal outcome \( y_j \). Second, there is a binary variable that indicates whether each case in the sample is observed or unobserved. To handle the sample-selection problem, we model both dependent variables jointly. Both variables are categorical. Their categorical values are determined by the values of linear combinations of covariates and normally distributed error terms relative to certain cutpoints that partition the real line. The error terms used in the determination of selection and the ordinal outcome value may be correlated.

The probability that the ordinal outcome \( y_j \) is equal to the value \( v_h \) is given by the probability that \( x_j \beta + u_{1j} \) falls within the cutpoints \( \kappa_{h-1} \) and \( \kappa_h \),

\[
\Pr(y_j = v_h) = \Pr(\kappa_{h-1} < x_j \beta + u_{1j} \leq \kappa_h)
\]

where \( x_j \) is the outcome covariates, \( \beta \) is the coefficients, and \( u_{1j} \) is a random-error term. The observed outcome values \( v_1, \ldots, v_H \) are integers such that \( v_i < v_m \) for \( i < m \). \( \kappa_0 \) is taken as \(-\infty\) and \( \kappa_H \) is taken as \(+\infty\).

We model the selection process for the outcome by

\[
s_j = 1(z_j \gamma + u_{2j} > 0)
\]

where \( s_j = 1 \) if we observed \( y_j \) and 0 otherwise, \( z_j \) is the covariates used to model the selection process, \( \gamma \) is the coefficients for the selection process, \( 1(\cdot) \) denotes the indicator function, and \( u_{2j} \) is a random-error term.

\( (u_{1j}, u_{2j}) \) have bivariate normal distribution with mean zero and variance matrix

\[
\begin{bmatrix}
1 & \rho \\
\rho & 1
\end{bmatrix}
\]

When \( \rho \neq 0 \), standard ordered probit techniques applied to the outcome equation yield inconsistent results. \texttt{heckoprobit} provides consistent, asymptotically efficient estimates for all the parameters in such models.

De Luca and Perotti (2011) describe the maximum likelihood estimator used in \texttt{heckoprobit}.

\textbf{Example 1}

We have a simulated dataset containing a sample of 5,000 women, 3,480 of whom work. The outcome of interest is a woman’s job satisfaction, and we suspect that unobservables that determine job satisfaction and the unobservables that increase the likelihood of employment are correlated. Women may make a decision to work based on how satisfying their job would be. We estimate the parameters of an ordered probit sample-selection model for the outcome of job satisfaction (\texttt{satisfaction}) with selection on employment (\texttt{work}). Age (\texttt{age}) and years of education (\texttt{education}) are used as outcome covariates, and we also expect that they affect selection. Additional covariates for selection are marital status (\texttt{married}) and the number of children at home (\texttt{children}).

Here we estimate the parameters of the model with \texttt{heckoprobit}. We use the factorial interaction of \texttt{married} and \texttt{children} in \texttt{select()}. This specifies that the number of children and marital status affect selection, and it allows the effect of the number of children to differ among married and nonmarried women. The factorial interaction is specified using factor-variable notation, which is described in [U] 11.4.3 Factor variables.

| /cut2      | 2.64357 | .116586   | 22.67  | 0.000 | 2.415066 2.872075    |
| /cut3      | 3.642911| .1178174  | 30.92  | 0.000 | 3.411993 3.873829    |
| /athrho    | .7430919| .0780998  | 9.51   | 0.000 | .5900191 .8961646    |
| rho        | .6310096| .0470026  | .529903| 0.7144252|

LR test of indep. eqns. (rho = 0): chi2(1) = 88.10 Prob > chi2 = 0.0000

The output shows several iteration logs. The first iteration log corresponds to running the ordered probit model for those observations in the sample where we have observed the outcome. The second iteration log corresponds to running the selection probit model, which models whether we observe
our outcome of interest. If $\rho = 0$, the sum of the log likelihoods from these two models will equal the log likelihood of the ordered probit sample-selection model; this sum is printed in the iteration log as the comparison log likelihood. The final iteration log is for fitting the full ordered probit sample-selection model.

The Wald test in the header is highly significant, indicating a good model fit. All the covariates are statistically significant. The likelihood-ratio test in the footer indicates that we can reject the null hypothesis that the errors for outcome and selection are uncorrelated. This means that we should use the ordered probit sample-selection model instead of the simple ordered probit model.

The positive estimate of 0.63 for $\rho$ indicates that unobservables that increase job satisfaction tend to occur with unobservables that increase the chance of having a job.

Stored results

`heckoprobit` stores the following in `e()`:

Scalars

- `e(N)` number of observations
- `e(N_cens)` number of censored observations
- `e(N_cd)` number of completely determined observations
- `e(k_cat)` number of categories
- `e(k)` number of parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_aux)` number of auxiliary parameters
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(ll)` log likelihood
- `e(ll_c)` log likelihood, comparison model
- `e(N_clust)` number of clusters
- `e(chi2)` $\chi^2$
- `e(chi2_c)` $\chi^2$ for comparison test
- `e(p_c)` $p$-value for comparison test
- `e(p)` significance of comparison test
- `e(rho)` $\rho$
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise
Methods and formulas

De Luca and Perotti (2011) provide an introduction to this model.

The ordinal outcome equation is

\[ y_j = \sum_{h=1}^{H} v_h \mathbb{1}(\kappa_{h-1} < x_j \beta + u_{1j} \leq \kappa_h) \]

where \( x_j \) is the outcome covariates, \( \beta \) is the coefficients, and \( u_{1j} \) is a random-error term. The observed outcome values \( v_1, \ldots, v_H \) are integers such that \( v_i < v_m \) for \( i < m \). \( \kappa_1, \ldots, \kappa_{H-1} \) are real numbers such that \( \kappa_i < \kappa_m \) for \( i < m \). \( \kappa_0 \) is taken as \(-\infty\) and \( \kappa_H \) is taken as \(+\infty\).

The selection equation is

\[ s_j = \mathbb{1}(z_j \gamma + u_{2j} > 0) \]

where \( s_j = 1 \) if we observed \( y_j \) and 0 otherwise, \( z_j \) is the covariates used to model the selection process, \( \gamma \) is the coefficients for the selection process, and \( u_{2j} \) is a random-error term.
\((u_{1j}, u_{2j})\) have bivariate normal distribution with mean zero and variance matrix

\[
\begin{bmatrix}
1 & \rho \\
\rho & 1
\end{bmatrix}
\]

Let \(a_j = z_j \gamma + \text{offset}_j^\gamma\) and \(b_j = x_j \beta + \text{offset}_j^\beta\). This yields the log likelihood

\[
\ln L = \sum_{j \notin S} w_j \ln \{\Phi(-a_j)\} + \sum_{h=1}^{H} \sum_{j \in S, y_j = v_h} w_j \ln \{\Phi_2(a_j, \kappa_h - b_j, -\rho) - \Phi_2(a_j, \kappa_{h-1} - b_j, -\rho)\}
\]

where \(S\) is the set of observations for which \(y_j\) is observed, \(\Phi_2(\cdot)\) is the cumulative bivariate normal distribution function (with mean \([0 0]\)'), \(\Phi(\cdot)\) is the standard cumulative normal, and \(w_j\) is an optional weight for observation \(j\).

In the maximum likelihood estimation, \(\rho\) is not directly estimated. Directly estimated is \(\text{atanh}\ \rho\):

\[
\text{atanh} \ \rho = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right)
\]

From the form of the likelihood, it is clear that if \(\rho = 0\), the log likelihood for the ordered probit sample-selection model is equal to the sum of the ordered probit model for the outcome \(y\) and the selection model. We can perform a likelihood-ratio test by comparing the log likelihood of the full model with the sum of the log likelihoods for the ordered probit and selection models.

If you do not specify outcome(), pmargin (with one new variable specified) assumes outcome(#1).

You specify one or k new variables with pmargin, where k is the number of outcomes.

You specify one new variable with psel, xb, stdp, xbsel, and stdpsel.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

- **pmargin**, the default, calculates the predicted marginal probabilities.

  You specify one or k new variables, where k is the number of categories of the outcome variable $y_j$. If you specify the outcome() option, you must specify one new variable. If you specify one new variable and do not specify outcome(), outcome(#1) is assumed.
When `outcome()` is specified, the marginal probability that $y_j$ is equal to the level specified is calculated. When `outcome()` is not specified, the marginal probabilities for each outcome level are calculated.

`p1` calculates the predicted bivariate probabilities of outcome levels with selection.

You specify one or $k$ new variables, where $k$ is the number of categories of the outcome variable $y_j$. If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the bivariate probability that $y_j$ is equal to the level specified and that $y_j$ is observed is calculated. When `outcome()` is not specified, the bivariate probabilities for each outcome level and selection are calculated.

`p0` calculates the predicted bivariate probabilities of outcome levels with no selection.

You specify one or $k$ new variables, where $k$ is the number of categories of the outcome variable $y_j$. If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the bivariate probability that $y_j$ is equal to the level specified and that $y_j$ is not observed is calculated. When `outcome()` is not specified, the bivariate probabilities for each outcome level and no selection are calculated.

`pcond1` calculates the predicted probabilities of outcome levels conditional on selection.

You specify one or $k$ new variables, where $k$ is the number of categories of the outcome variable $y_j$. If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the probability that $y_j$ is equal to the level specified given that $y_j$ is observed is calculated. When `outcome()` is not specified, the probabilities for each outcome level conditional on selection are calculated.

`pcond0` calculates the predicted probabilities of outcome levels conditional on no selection.

You specify one or $k$ new variables, where $k$ is the number of categories of the outcome variable $y_j$. If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the probability that $y_j$ is equal to the level specified given that $y_j$ is not observed is calculated. When `outcome()` is not specified, the probabilities for each outcome level conditional on no selection are calculated.

`psel` calculates the predicted univariate (marginal) probability of selection.

`xb` calculates the linear prediction for the outcome variable, which is $x_j \beta$ if `offset()` was not specified and $x_j \beta + \text{offset}_j \beta$ if `offset()` was specified.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation’s covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`xbsel` calculates the linear prediction for the selection equation, which is $z_j \gamma$ if `offset()` was not specified in `select()` and $z_j \gamma + \text{offset}_j \gamma$ if `offset()` was specified in `select()`.

`stdpsel` calculates the standard error of the linear prediction for the selection equation.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc.
nooffset is relevant only if you specified offset(varname) for heckoprobit. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $x_j b$ rather than as $x_j b + \text{offset}_j$.

scores calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial (x_j \beta)$.

The second new variable will contain $\partial \ln L / \partial (z_j \gamma)$.

When the dependent variable takes $k$ different values, new variables three through $k + 1$ will contain $\partial \ln L / \partial (\kappa_{j-2})$.

The last new variable will contain $\partial \ln L / \partial (\text{atanh } \rho)$.

margins

Description for margins

margins estimates margins of response for probabilities and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

\begin{verbatim}
margins [\textit{marginlist}] [, \textit{options}]  
margins [\textit{marginlist}] , \texttt{predict} (\textit{statistic} ...) [\texttt{predict} (\textit{statistic} ...) ...] [\textit{options}]

\textbf{statistic} & \textbf{Description} \\
\hline
\texttt{default} & marginal probabilities for each outcome \\
\texttt{pmargin} & marginal probabilities \\
p1 & bivariate probabilities of levels with selection \\
p0 & bivariate probabilities of levels with no selection \\
pcond1 & probabilities of levels conditional on selection \\
pcond0 & probabilities of levels conditional on no selection \\
psel & selection probability \\
xb & linear prediction \\
xbsel & linear prediction for selection equation \\
\tt{stdp} & not allowed with \tt{margins} \\
\tt{stdpsel} & not allowed with \tt{margins} \\
\end{tabular}

\texttt{pmargin}, \texttt{p1}, \texttt{p0}, \texttt{pcond1}, and \texttt{pcond0} default to the first outcome.

Statistics not allowed with \tt{margins} are functions of stochastic quantities other than $e(b)$.

For the full syntax, see [R] margins.
Remarks and examples

Example 1

In example 1 of \texttt{[R} heckoprobit\texttt{]}, we examined a simulated dataset of 5,000 women, 3,480 of whom work and can thus report job satisfaction. Using job satisfaction (\texttt{satisfaction}) as the outcome variable and employment (\texttt{work}) as the selection variable, we estimated the parameters of an ordered probit sample-selection model. Covariates age (\texttt{age}), years of education (\texttt{education}), number of children (\texttt{children}), and marital status (\texttt{married}) are expected to affect selection. The outcome, job satisfaction, is affected by age (\texttt{age}) and education (\texttt{education}).

We first reestimate the parameters of the regression, but this time we request a robust variance estimator:

\begin{verbatim}
   . use http://www.stata-press.com/data/r14/womensat
   (Job satisfaction, female)
   . heckoprobit satisfaction education age,
      > select(work=education age i.married##c.children) vce(robust)
\end{verbatim}

We then use \texttt{margins} (see \texttt{[R} margins\texttt{]) to estimate the average marginal effect of education on the probability of having low job satisfaction.

\begin{verbatim}
   . margins, dydx(education) vce(unconditional)
   Average marginal effects Number of obs = 5,000
   dy/dx w.r.t. : education
   1._predict : Pr(satisfaction=1), predict(pmargin outcome(1))
   2._predict : Pr(satisfaction=2), predict(pmargin outcome(2))
   3._predict : Pr(satisfaction=3), predict(pmargin outcome(3))
   4._predict : Pr(satisfaction=4), predict(pmargin outcome(4))

<table>
<thead>
<tr>
<th>Unconditional</th>
</tr>
</thead>
<tbody>
<tr>
<td>dy/dx   Std. Err.  z   P&gt;</td>
</tr>
<tr>
<td>---------------------</td>
</tr>
</tbody>
</table>
   education _predict   |
   1    -.0234776    .0019176 -12.24 0.000    -.027236   -.0197192 |
   2    -.0230858    .0015143 -15.24 0.000    -.0260538   -.0201178 |
   3    -.0020603    .001142  -1.80 0.071   -.0042987    .000178  |
   4     .0486238    .0018593  26.15 0.000   .0449795    .052268  |
\end{verbatim}

The estimated average marginal effect of education on the probability of having low job satisfaction is approximately $-0.023$.

Methods and formulas

The ordinal outcome equation is

$$y_j = \sum_{h=1}^{H} v_h \mathbb{1}(\kappa_{h-1} < x_j \beta + u_{1j} \leq \kappa_h)$$

where $x_j$ is the outcome covariates, $\beta$ is the coefficients, and $u_{1j}$ is a random-error term. The observed outcome values $v_1, \ldots, v_H$ are integers such that $v_i < v_m$ for $i < m$. $\kappa_1, \ldots, \kappa_{H-1}$ are real numbers such that $\kappa_i < \kappa_m$ for $i < m$. $\kappa_0$ is taken as $-\infty$ and $\kappa_H$ is taken as $+\infty$. 

\[\text{output omitted}\]
The selection equation is

\[ s_j = 1(z_j \gamma + u_{2j} > 0) \]

where \( s_j = 1 \) if we observed \( y_j \) and 0 otherwise, \( z_j \) is the covariates used to model the selection process, \( \gamma \) is the coefficients for the selection process, and \( u_{2j} \) is a random-error term.

\((u_{1j}, u_{2j})\) have bivariate normal distribution with mean zero and variance matrix

\[
\begin{bmatrix}
1 & \rho \\
\rho & 1
\end{bmatrix}
\]

The probability of selection is

\[ \Pr(s_j = 1) = \Phi(z_j \gamma + \text{offset}_j) \]

\( \Phi(\cdot) \) is the standard cumulative normal distribution function.

The probability of selection and the outcome \( y_j = v_h \) is

\[
\Pr(y_j = v_h, s_j = 1) = \Phi_2(z_j \gamma + \text{offset}_j, \kappa_h - x_j \beta - \text{offset}_j, -\rho) - \Phi_2(z_j \gamma + \text{offset}_j, \kappa_{h-1} - x_j \beta - \text{offset}_j, -\rho)
\]

\( \Phi_2(\cdot) \) is the cumulative bivariate normal distribution function (with mean \([0 0]'\)).

The probability of \( y_j \) not being selected and the outcome \( y_j = v_h \) is

\[
\Pr(y_j = v_h, s_j = 0) = \Phi_2(-z_j \gamma - \text{offset}_j, \kappa_h - x_j \beta - \text{offset}_j, \rho) - \Phi_2(-z_j \gamma - \text{offset}_j, \kappa_{h-1} - x_j \beta - \text{offset}_j, \rho)
\]

The probability of outcome \( y_j = v_h \) given selection is

\[
\Pr(y_j = v_h | s_j = 1) = \frac{\Pr(y_j = v_h, s_j = 1)}{\Pr(s_j = 1)}
\]

The probability of outcome \( y_j = v_h \) given \( y_j \) is not selected is

\[
\Pr(y_j = v_h | s_j = 0) = \frac{\Pr(y_j = v_h, s_j = 0)}{\Pr(s_j = 0)}
\]

The marginal probabilities of the outcome \( y_j \) are

\[
\begin{align*}
\Pr(y_j = v_1) &= \Phi(\kappa_1 - x_j \beta - \text{offset}_j) \\
\Pr(y_j = v_H) &= 1 - \Phi(\kappa_{H-1} - x_j \beta - \text{offset}_j) \\
\Pr(y_j = v_h) &= \Phi(\kappa_h - x_j \beta - \text{offset}_j) - \Phi(\kappa_{h-1} - x_j \beta - \text{offset}_j)
\end{align*}
\]

**Description**

`heckprobit` fits maximum-likelihood probit models with sample selection. `heckprob` is a synonym for `heckprobit`.

**Quick start**

Probit model of $y$ on $x$ with sample selection indicated by binary variable `selected` and predicted by $v$

```
heckprobit y x, select(selected = v x)
```

Suppress iteration log

```
heckprobit y x, select(selected = v x) nolog
```

With cluster–robust standard errors for clustering by levels of `cvar`

```
heckprobit y x, select(selected = v x) vce(cluster cvar)
```

**Menu**

Statistics > Sample-selection models > Probit model with sample selection
**Syntax**

```plaintext
heckprobit  depvar indepvars [ if ] [ in ] [ weight ] ,
    select( [ depvars = ] varlist [, noconstant offset(varname_o) ] ) [ options ]
```

**options**

**SE/Robust**

| vce(vcetype)                 | vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife |

**Reporting**

| level(#)                      | set confidence level; default is level(95) |
| first                        | report first-step probit estimates          |
| noskip                       | perform likelihood-ratio test              |
| nocnsreport                  | do not display constraints                  |
| display_options              | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |

**Maximization**

| maximize_options             | control the maximization process; seldom used |
| coeflegend                   | display legend instead of statistics         |

*select() is required.

The full specification is `select( [ depvars = ] varlist [, noconstant offset(varname_o) ] )`.

indepvars and varlist may contain factor variables; see [U] 11.4.3 Factor variables.
depvar, indepvars, depvar, and varlist may contain time-series operators; see [U] 11.4.4 Time-series varlists.
bootstrap, by, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
vce(), first, noskip, and weights are not allowed with the svy prefix; see [SVY] svy.
pweights, fweights, and iweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

**Options**

Model

`select([ depvars = ] varlist [, noconstant offset(varname_o) ] )` specifies the variables and options for the selection equation. It is an integral part of specifying a selection model and is required. The selection equation should contain at least one variable that is not in the outcome equation.
If \( \text{depvar} \) is specified, it should be coded as 0 or 1, 0 indicating an observation not selected and 1 indicating a selected observation. If \( \text{depvar} \) is not specified, observations for which \( \text{depvar} \) is not missing are assumed selected, and those for which \( \text{depvar} \) is missing are assumed not selected.

\noconstant\ suppresses the selection constant term (intercept).

\offset(varname)\ specifies that selection offset \( \text{varname} \) be included in the model with the coefficient constrained to be 1.

\noconstant, \offset(varname), \constraints(constraints), \collinear; \text{see } [R] \text{ estimation options}.

\vce(vcetype)\ specifies the type of standard error reported, which includes types that are derived from asymptotic theory (\text{opg}, \text{opg}), that are robust to some kinds of misspecification (\text{robust}), that allow for intragroup correlation (\text{cluster clustvar}), and that use bootstrap or jackknife methods (\text{bootstrap}, \text{jackknife}); \text{see } [R] \text{ vce_option}.

\level(#)\; \text{see } [R] \text{ estimation options}.

\first\ specifies that the first-step probit estimates of the selection equation be displayed before estimation.

\noskip\ specifies that a full maximum-likelihood model with only a constant for the regression equation be fit. This model is not displayed but is used as the base model to compute a likelihood-ratio test for the model test statistic displayed in the estimation header. By default, the overall model test statistic is an asymptotically equivalent Wald test that all the parameters in the regression equation are zero (except the constant). For many models, this option can substantially increase estimation time.

\nocnsreport; \text{see } [R] \text{ estimation options}.

\display_options: \text{noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabel, fvwrap(#), fvwrapon(style), cformat(\%fmt), pformat(\%fmt), sformat(\%fmt), and nolstretch}; \text{see } [R] \text{ estimation options}.

\maximize_options: \text{difficult, technique(algorithm_spec), iterate(#), no} \text{log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs)}; \text{see } [R] \text{ maximize}. \text{These options are seldom used.}

Setting the optimization type to \text{technique(bhhh)} resets the default \text{vcetype} to \text{vce(opg)}.

The following option is available with \text{heckprobit} but is not shown in the dialog box:
\coeflegend; \text{see } [R] \text{ estimation options}. 
Remarks and examples

The probit model with sample selection (Van de Ven and Van Pragg 1981) assumes that there exists an underlying relationship

\[ y_j^* = x_j \beta + u_{1j} \quad \text{latent equation} \]

such that we observe only the binary outcome

\[ y_j^{\text{probit}} = (y_j^* > 0) \quad \text{probit equation} \]

The dependent variable, however, is not always observed. Rather, the dependent variable for observation \( j \) is observed if

\[ y_j^{\text{select}} = (z_j \gamma + u_{2j} > 0) \quad \text{selection equation} \]

where

- \( u_1 \sim N(0, 1) \)
- \( u_2 \sim N(0, 1) \)
- \( \text{corr}(u_1, u_2) = \rho \)

When \( \rho \neq 0 \), standard probit techniques applied to the first equation yield biased results. \texttt{heckprobit} provides consistent, asymptotically efficient estimates for all the parameters in such models.

For the model to be well identified, the selection equation should have at least one variable that is not in the probit equation. Otherwise, the model is identified only by functional form, and the coefficients have no structural interpretation.

Example 1

We use the data from Pindyck and Rubinfeld (1998). In this dataset, the variables are whether children attend private school (\texttt{private}), number of years the family has been at the present residence (\texttt{years}), log of property tax (\texttt{logptax}), log of income (\texttt{loginc}), and whether one voted for an increase in property taxes (\texttt{vote}).

In this example, we alter the meaning of the data. Here we assume that we observe whether children attend private school only if the family votes for increasing the property taxes. This assumption is not true in the dataset, and we make it only to illustrate the use of this command.

We observe whether children attend private school only if the head of household voted for an increase in property taxes. We assume that the vote is affected by the number of years in residence, the current property taxes paid, and the household income. We wish to model whether children are sent to private school on the basis of the number of years spent in the current residence and the current property taxes paid.

| /athrho | -.8663164 | 1.450017  | -0.60 | 0.550 | -3.708298 1.975665 |
| rho     | -.6994978 | .7405281  | - .590 | -.9987983 .9622674 |

LR test of indep. eqns. (rho = 0): chi2(1) = 0.27 Prob > chi2 = 0.6020

The output shows several iteration logs. The first iteration log corresponds to running the probit model for those observations in the sample where we have observed the outcome. The second iteration log corresponds to running the selection probit model, which models whether we observe our outcome of interest. If $\rho = 0$, the sum of the log likelihoods from these two models will equal the log likelihood of the probit model with sample selection; this sum is printed in the iteration log as the comparison log likelihood. The third iteration log shows starting values for the iterations.
The final iteration log is for fitting the full probit model with sample selection. A likelihood-ratio test of the log likelihood for this model and the comparison log likelihood is presented at the end of the output. If we had specified the \texttt{vce(robust)} option, this test would be presented as a Wald test instead of as a likelihood-ratio test.

\section*{Example 2}

In example 1, we could have obtained robust standard errors by specifying the \texttt{vce(robust)} option. We do this here and also eliminate the iteration logs by using the \texttt{nolog} option:

\begin{verbatim}
. heckprobit private years logptax, sel(vote=years loginc logptax) vce(robust) > nolog
Probit model with sample selection
Number of obs = 95
Censored obs = 36
Uncensored obs = 59
Wald chi2(2) = 2.55
Log pseudolikelihood = -74.24497
Prob > chi2 = 0.2798

Robust
| Coef. Std. Err. z  P>|z|      [95% Conf. Interval] |
|----------------|-----------------|---------|----------|------------------|
| private | years | -.1142596 | .1113968 | -1.03 | 0.305 | -.3325934 | .1040741 |
|         | logptax | .3516101 | .7358211 | 0.48 | 0.633 | -1.090573 | 1.793793 |
|         | _cons  | -2.780667 | 4.786652 | -0.58 | 0.561 | -12.16233 | 6.600998 |
| vote   | years | -.0167511 | .0173344 | -0.97 | 0.334 | -.0507259 | .0172237 |
|         | loginc | .9923023 | .4228042 | 2.35 | 0.019 | .1636213 | 1.820983 |
|         | logptax | -1.278783 | .5095156 | -2.51 | 0.012 | -2.277415 | -.2801506 |
|         | _cons  | -.5458205 | 4.54389 | -0.12 | 0.904 | -9.451682 | 8.360041 |
| /athrho |       | -.8663164 | 1.63062 | -0.53 | 0.595 | -4.062272 | 2.329639 |
| rho    |       | -.6994978 | .8327621 | 0.28 | 0.784 | -.9994078 | .9812312 |

Wald test of indep. eqns. (rho = 0): chi2(1) = 0.28  Prob > chi2 = 0.60952
\end{verbatim}

Regardless of whether we specify the \texttt{vce(robust)} option, the outcome is not significantly different from the outcome obtained by fitting the probit and selection models separately. This result is not surprising because the selection mechanism estimated was invented for the example rather than borne from any economic theory.

Methods and formulas

Van de Ven and Van Pragg (1981) provide an introduction and an explanation of this model.

The probit equation is

\[ y_j = (x_j\beta + u_{1j} > 0) \]

The selection equation is

\[ z_j\gamma + u_{2j} > 0 \]

where

\[ u_1 \sim N(0, 1) \]
\[ u_2 \sim N(0, 1) \]
\[ \text{corr}(u_1, u_2) = \rho \]

The log likelihood is

\[
\ln L = \sum_{j \in S, y_j \neq 0} w_j \ln \left\{ \Phi_2 \left( x_j\beta + \text{offset}_j\beta, z_j\gamma + \text{offset}_j\gamma, \rho \right) \right\} \\
+ \sum_{j \in S, y_j = 0} w_j \ln \left\{ \Phi_2 \left( -x_j\beta + \text{offset}_j\beta, z_j\gamma + \text{offset}_j\gamma, -\rho \right) \right\} \\
+ \sum_{j \notin S} w_j \ln \left\{ 1 - \Phi \left( z_j\gamma + \text{offset}_j\gamma \right) \right\}
\]

where \( S \) is the set of observations for which \( y_j \) is observed, \( \Phi_2(\cdot) \) is the cumulative bivariate normal distribution function (with mean \( [0 \ 0]' \)), \( \Phi(\cdot) \) is the standard cumulative normal, and \( w_j \) is an optional weight for observation \( j \).

In the maximum likelihood estimation, \( \rho \) is not directly estimated. Directly estimated is \( \text{atanh} \rho \):

\[
\text{atanh} \rho = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right)
\]

From the form of the likelihood, it is clear that if \( \rho = 0 \), the log likelihood for the probit model with sample selection is equal to the sum of the probit model for the outcome \( y \) and the selection model. We can perform a likelihood-ratio test by comparing the likelihood of the full model with the sum of the log likelihoods for the probit and selection models.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using vce(robust) and vce(cluster clustvar), respectively. See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas.

heckprobit also supports estimation with survey data. For details on VCEs with survey data, see [SVY] variance estimation.

## Postestimation commands

The following postestimation commands are available after `heckprobit`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>contrast</code></td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td><code>estat ic</code></td>
<td>Akaike’s and Schwarz’s Bayesian information criteria (AIC and BIC)</td>
</tr>
<tr>
<td><code>estat summarize</code></td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td><code>estat vce</code></td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td><code>estat (svy)</code></td>

where Φ(·) is the standard normal distribution function and Φ_2(·) is the bivariate normal distribution function.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

- `pmargin`, the default, calculates the univariate (marginal) predicted probability of success Pr(y_j^probit = 1).
- `p11` calculates the bivariate predicted probability Pr(y_j^probit = 1, y_j^select = 1).
- `p10` calculates the bivariate predicted probability Pr(y_j^probit = 1, y_j^select = 0).
p01 calculates the bivariate predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 1)$.

p00 calculates the bivariate predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 0)$.

psel calculates the univariate (marginal) predicted probability of selection $\Pr(y_j^{\text{select}} = 1)$.

pcond calculates the conditional (on selection) predicted probability of success $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 1)/\Pr(y_j^{\text{select}} = 1)$.

xb calculates the probit linear prediction $x_j \beta$.

stdp calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation’s covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

xbsel calculates the linear prediction for the selection equation.

stdpsel calculates the standard error of the linear prediction for the selection equation.

nooffset is relevant only if you specified offset(varname) for heckprobit. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $x_j \beta$ rather than as $x_j \beta + \text{offset}_j$.

scores calculates equation-level score variables.

  The first new variable will contain $\partial \ln L/\partial (x_j \beta)$.
  The second new variable will contain $\partial \ln L/\partial (z_j \gamma)$.
  The third new variable will contain $\partial \ln L/\partial (\text{atanh } \rho)$.
margins

Description for margins

margins estimates margins of response for probabilities and linear predictions.

Menu for margins

</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than \( e(b) \).

For the full syntax, see [R] margins.
Remarks and examples

Example 1

It is instructive to compare the marginal predicted probabilities with the predicted probabilities that we would obtain by ignoring the selection mechanism. To compare the two approaches, we will synthesize data so that we know the “true” predicted probabilities.

First, we need to generate correlated error terms, which we can do using a standard Cholesky decomposition approach. For our example, we will clear any data from memory and then generate errors that have a correlation of 0.5 by using the following commands. We set the seed so that interested readers can type in these same commands and obtain the same results.

\[
\begin{align*}
\text{. set seed 12309} \\
\text{. set obs 5000} \\
\text{number of observations (} _{\text{N}}\text{) was 0, now 5,000} \\
\text{. generate } c1 = \text{rnormal()} \\
\text{. generate } c2 = \text{rnormal()} \\
\text{. matrix } P = (1,.5\,.5,1) \\
\text{. matrix } A = \text{cholesky}(P) \\
\text{. local } fac1 = A[2,1] \\
\text{. local } fac2 = A[2,2] \\
\text{. generate } u1 = c1 \\
\text{. generate } u2 = 'fac1'*c1 + 'fac2'*c2
\end{align*}
\]

We can check that the errors have the correct correlation by using the \texttt{correlate} command. We will also normalize the errors so that they have a standard deviation of one, so we can generate a bivariate probit model with known coefficients. We do that with the following commands:

\[
\begin{align*}
\text{. correlate } u1 \text{ u2} \\
\text{(obs=5,000)} \\
\text{u1 u2} \\
\text{u1} & 1.0000 \\
\text{u2} & 0.5012 1.0000 \\
\text{. summarize } u1 \\
\text{(output omitted)} \\
\text{. replace } u1 = u1/\text{r(sd)} \\
\text{(5,000 real changes made)} \\
\text{. summarize } u2 \\
\text{(output omitted)} \\
\text{. replace } u2 = u2/\text{r(sd)} \\
\text{(5,000 real changes made)} \\
\text{. drop } c1 \text{ c2} \\
\text{. generate } x1 = \text{runiform()-0.5} \\
\text{. generate } x2 = \text{runiform()}+1/3 \\
\text{. generate } y1s = 0.5 + 4*x1 + u1 \\
\text{. generate } y2s = 3 - 3*x2 + 0.5*x1 + u2 \\
\text{. generate } y1 = (y1s>0) \\
\text{. generate } y2 = (y2s>0)
\end{align*}
\]

We have now created two dependent variables, \(y1\) and \(y2\), which are defined by our specified coefficients. We also included error terms for each equation, and the error terms are correlated. We run \texttt{heckprobit} to verify that the data have been correctly generated according to the model.
\[ y_1 = .5 + 4x_1 + u_1 \]
\[ y_2 = 3 + .5x_1 - 3x_2 + u_2 \]

where we assume that \( y_1 \) is observed only if \( y_2 = 1 \).

```
. heckprobit y1 x1, sel(y2 = x1 x2) nolog
Probit model with sample selection
Number of obs = 5,000
Censored obs = 1,818
Uncensored obs = 3,182
Wald chi2(1) = 947.76
Log likelihood = -3612.401 Prob > chi2 = 0.0000
```

LR test of indep. eqns. (rho = 0): chi2(1) = 41.36 Prob > chi2 = 0.0000

Now that we have verified that we have generated data according to a known model, we can obtain and then compare predicted probabilities from the probit model with sample selection and a (usual) probit model.

```
. predict pmarg
(option pmargin assumed; Pr(y1=1))
. probit y1 x1 if y2==1
(output omitted)
. predict phat
(option pr assumed; Pr(y1))
```

Using the (marginal) predicted probabilities from the probit model with sample selection (pmarg) and the predicted probabilities from the (usual) probit model (phat), we can also generate the “true” predicted probabilities from the synthesized y1s variable and then compare the predicted probabilities:

```
. generate ptrue = normal(y1s)
. summarize pmarg ptrue phat
```

Here we see that ignoring the selection mechanism (comparing the phat variable with the true ptrue variable) results in predicted probabilities that are much higher than the true values. Looking at the marginal predicted probabilities from the model with sample selection, however, results in more accurate predictions.

[U] 20 Estimation and postestimation commands
The `help` command displays help information about the specified command or topic. `help` launches a new Viewer to display help for the specified command or topic or displays help on the console in Stata for Unix(console). If `help` is not followed by a command or a topic name, Stata displays advice for using the help system and documentation.

**Menu**

Help > Stata command...

**Syntax**

```
help [command_or_topic_name] [ , nonew name(viewername) marker(markername) ]
```

**Options**

`nonew` specifies that a new Viewer window not be opened for the help topic if a Viewer window is already open. The default is for a new Viewer window to be opened each time `help` is typed so that multiple help files may be viewed at once. `nonew` causes the help file to be displayed in the topmost open Viewer.

`name(viewername)` specifies that help be displayed in a Viewer window named `viewername`. If the named window already exists, its contents will be replaced. If the named window does not exist, it will be created.

`marker(markername)` specifies that the help file be opened to the position of `markername` within the help file.

**Remarks and examples**

To obtain help for any Stata command, type `help command` or select Help > Stata command... and fill in `command`. 
help is best explained by examples.

To obtain help for ...

<table>
<thead>
<tr>

</tr>
<tr>
<td>help regress post</td>
</tr>
<tr>
<td>help graph xlabel()</td>
</tr>
<tr>
<td>help strpos()</td>
</tr>
<tr>
<td>help mata optimize()</td>
</tr>
</tbody>
</table>

Tips:

- help displays advice for using the help system and documentation.
- help guide displays a table of contents for basic Stata concepts.
- help estimation commands displays an alphabetical listing of all Stata estimation commands.
- help functions displays help on Stata functions by category.
- help mata functions displays a subject table of contents for Mata’s functions.
- help ts glossary displays the glossary for the time-series manual, and similarly for the other Stata specialty manuals.

If you type help topic and help for topic is not found, Stata will automatically perform a search for topic.

For instance, try typing help forecasting. A forecasting help file is not found, so Stata executes search forecasting and displays the results in the Viewer.

See [U] 4 Stata’s help and search facilities for a complete description of how to use help.

🚨 Technical note

When you type help topic, Stata first looks along the adopath for topic.sthlp; see [U] 17.5 Where does Stata look for ado-files?.

hetprobit — Heteroskedastic probit model

Description
hetprobit fits a maximum-likelihood heteroskedastic probit model.
hetprob is a synonym for hetprobit.

Quick start
Heteroskedastic probit model of \( y \) on \( x_1 \), using \( x_2 \) to model the variance
hetprobit \( y \) \( x_1 \), het(\( x_2 \))

With robust standard errors
hetprobit \( y \) \( x_1 \), het(\( x_2 \)) vce(robust)

After fitting a model, reprint the table as a coefficient legend
hetprobit, coeflegend

Menu
Statistics > Binary outcomes > Heteroskedastic probit regression

maximize_options                       control the maximization process; seldom used
```

```
coeflegend                             display legend instead of statistics
```

*`het()` is required. The full specification is `het(varlist[, offset(varname)])`. `indepvars` and `varlist` may contain factor variables; see [U] 11.4.3 Factor variables. `depvar`, `indepvars`, and `varlist` may contain time-series operators; see [U] 11.4.4 Time-series varlists. `bootstrap`, `by`, `fp`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap. `vce()`, `noskip`, and weights are not allowed with the `svy` prefix; see [SVY] svy. `fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight. `coeflegend` does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

### Options

- `het(varlist[, offset(varname)])` specifies the independent variables and the offset variable, if there is one, in the variance function. `het()` is required.
offset(varname) specifies that selection offset varname be included in the model with the coefficient constrained to be 1.

noconstant, offset(varname); see [R] estimation options.

asis forces the retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] probit.

constraints(constraints), collinear; see [R] estimation options.

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

level(#); see [R] estimation options.

noskip requests fitting of the constant-only model and calculation of the corresponding likelihood-ratio \( \chi^2 \) statistic for testing significance of the full model. By default, a Wald \( \chi^2 \) statistic is computed for testing the significance of the full model.

nolrtest specifies that a Wald test of whether \( \lnsigma2 = 0 \) be performed instead of the LR test. nocnsreport; see [R] estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabel, fvwrap(#), fvwrapon(style), cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch; see [R] estimation options.

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] maximize. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following option is available with hetprobit but is not shown in the dialog box: coeflegend; see [R] estimation options.

Remarks and examples

Remarks are presented under the following headings:

Introduction
Robust standard errors
hetprobit — Heteroskedastic probit model

Introduction

hetprobit fits a maximum-likelihood heteroskedastic probit model, which is a generalization of the probit model. Let \( y_j, j = 1, \ldots, N \), be a binary outcome variable taking on the value 0 (failure) or 1 (success). In the probit model, the probability that \( y_j \) takes on the value 1 is modeled as a nonlinear function of a linear combination of the \( k \) independent variables \( x_j = (x_{1j}, x_{2j}, \ldots, x_{kj}) \),

\[
\Pr(y_j = 1) = \Phi(x_j b)
\]

in which \( \Phi() \) is the cumulative distribution function (CDF) of a standard normal random variable, that is, a normally distributed (Gaussian) random variable with mean 0 and variance 1. The linear combination of the independent variables, \( x_j b \), is commonly called the index function, or index. Heteroskedastic probit generalizes the probit model by generalizing \( \Phi() \) to a normal CDF with a variance that is no longer fixed at 1 but can vary as a function of the independent variables. hetprobit models the variance as a multiplicative function of these \( m \) variables \( z_j = (z_{1j}, z_{2j}, \ldots, z_{mj}) \), following Harvey (1976):

\[
\sigma_j^2 = \{ \exp(z_j \gamma) \}^2
\]

Thus the probability of success as a function of all the independent variables is

\[
\Pr(y_j = 1) = \Phi \left\{ x_j b / \exp(z_j \gamma) \right\}
\]

From this expression, it is clear that, unlike the index \( x_j b \), no constant term can be present in \( z_j \gamma \) if the model is to be identifiable.

Suppose that the binary outcomes \( y_j \) are generated by thresholding an unobserved random variable, \( w_j \), which is normally distributed with mean \( x_j b \) and variance 1 such that

\[
y_j = \begin{cases} 
1 & \text{if } w_j > 0 \\
0 & \text{if } w_j \leq 0
\end{cases}
\]

This process gives the probit model:

\[
\Pr(y_j = 1) = \Pr(w_j > 0) = \Phi(x_j b)
\]

Now suppose that the unobserved \( w_j \) are heteroskedastic with variance

\[
\sigma_j^2 = \{ \exp(z_j \gamma) \}^2
\]

Relaxing the homoskedastic assumption of the probit model in this manner yields our multiplicative heteroskedastic probit model:

\[
\Pr(y_j = 1) = \Phi \left\{ x_j b / \exp(z_j \gamma) \right\}
\]
Example 1

For this example, we generate simulated data for a simple heteroskedastic probit model and then estimate the coefficients with `hetprobit`:

```
. set obs 1000
    number of observations (_N) was 0, now 1,000
. set seed 1234567

LR test of lnsigma2=0:  chi2(1) = 20.69  Prob > chi2 = 0.0000

Above we created two variables, x and xhet, and then simulated the model

\[ \Pr(y = 1) = F\left\{\frac{(\beta_0 + \beta_1 x)}{\exp(\gamma_1 xhet)}\right\} \]

for \( \beta_0 = 0.3, \beta_1 = 2, \) and \( \gamma_1 = 1.5 \). According to `hetprobit`'s output, all coefficients are significant, and, as we would expect, the Wald test of the full model versus the constant-only model—for example, the index consisting of \( \beta_0 + \beta_1 x \) versus that of just \( \beta_0 \)—is significant with \( \chi^2(1) = 54 \). Likewise, the likelihood-ratio test of heteroskedasticity, which tests the full model with heteroskedasticity against the full model without, is significant with \( \chi^2(1) = 21 \). See \([R]\) `maximize` for more explanation of the output. For this simple model, `hetprobit` took five iterations to converge. As stated elsewhere (Greene 2012, 714), this is a difficult model to fit, and it is not uncommon for it to require many iterations or for the optimizer to print out warnings and informative messages during the optimization. Slow convergence is especially common for models in which one or more of the independent variables appear in both the index and variance functions.
Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if your dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

Robust standard errors

If you specify the `vce(robust)` option, `hetprobit` reports robust standard errors as described in [U] 20.21 Obtaining robust variance estimates. To illustrate the effect of this option, we will reestimate our coefficients by using the same model and data in our example, this time adding `vce(robust)` to our `hetprobit` command.

```
Example 2

. hetprobit y x, het(xhet) vce(robust) nolog
```

```
Heteroskedastic probit model
Number of obs = 1,000
Zero outcomes = 451
Nonzero outcomes = 549
Wald chi2(1) = 50.49
Log pseudolikelihood = -600.0152 Prob > chi2 = 0.0000

Robust
y Coef. Std. Err. z P>|z| [95% Conf. Interval]
x 1.782479 .2508447 7.11 0.000 1.290832 2.274126
_cons .3140616 .087195 3.60 0.000 .1431625 .4849607

lnsigma2 Coef. Std. Err. z P>|z| [95% Conf. Interval]
xhet 1.31152 .3059137 4.29 0.000 .7119406 1.91111

Wald test of lnsigma2=0: chi2(1) = 18.38 Prob > chi2 = 0.0000
```

The `vce(robust)` standard errors for two of the three parameters are larger than the previously reported conventional standard errors. This is to be expected, even though (by construction) we have perfect model specification because this option trades off efficient estimation of the coefficient variance–covariance matrix for robustness against misspecification.

Specifying the `vce(cluster clustvar)` option relaxes the usual assumption of independence between observations to the weaker assumption of independence just between clusters; that is, `hetprobit`, `vce(cluster clustvar)` is robust with respect to within-cluster correlation. This option is less efficient than the `xtgee` population-averaged models because `hetprobit` inefficiently sums within cluster for the standard-error calculation rather than attempting to exploit what might be assumed about the within-cluster correlation.
hetprobit stores the following in \( e() \):

**Scalars**
- \( e(N) \): number of observations
- \( e(N_0) \): number of zero outcomes
- \( e(N_0s) \): number of nonzero outcomes
- \( e(k) \): number of parameters
- \( e(k_eq) \): number of equations in \( e(b) \)
- \( e(k_eq_model) \): number of equations in overall model test
- \( e(k_dv) \): number of dependent variables
- \( e(df_m) \): model degrees of freedom
- \( e(ll) \): log likelihood
- \( e(ll_0) \): log likelihood, constant-only model
- \( e(ll_c) \): log likelihood, comparison model
- \( e(ll_c) \): number of clusters
- \( e(ll2) \): \( \chi^2 \) for heteroskedasticity LR test
- \( e(ll2_c) \): degrees of freedom for heteroskedasticity LR test
- \( e(ll2_c) \): significance
- \( e(rank) \): rank of \( e(V) \)
- \( e(rank_0) \): rank of \( e(V) \) for constant-only model
- \( e(ic) \): number of iterations
- \( e(rc) \): return code
- \( e(converged) \): 1 if converged, 0 otherwise

**Macros**
- \( e(cmd) \): \texttt{hetprobit}
- \( e(cmdline) \): command as typed
- \( e(depvar) \): name of dependent variable
- \( e(wtype) \): weight type
- \( e(wexp) \): weight expression
- \( e(title) \): title in estimation output
- \( e(clustvar) \): name of cluster variable
- \( e(offset1) \): offset for probit equation
- \( e(offset2) \): offset for variance equation
- \( e(chi2type) \): Wald or LR; type of model \( \chi^2 \) test
- \( e(chi2_ct) \): Wald or LR; type of model \( \chi^2 \) test corresponding to \( e(chi2_c) \)
- \( e(vce) \): \texttt{vce} specified in \texttt{vce()}
- \( e(vcetype) \): title used to label Std. Err.
- \( e(which) \): \texttt{max} or \texttt{min}; whether optimizer is to perform maximization or minimization
- \( e(method) \): requested estimation method
- \( e(ml_method) \): type of \texttt{ml} method
- \( e(user) \): name of likelihood-evaluator
- \( e(technique) \): maximization technique
- \( e(properties) \): \texttt{b \ V}
- \( e(predict) \): program used to implement \texttt{predict}
- \( e(asbalanced) \): factor variables \texttt{fvset} as \texttt{asbalanced}
- \( e(asobserved) \): factor variables \texttt{fvset} as \texttt{asobserved}

**Matrices**
- \( e(b) \): coefficient vector
- \( e(Cns) \): constraints matrix
- \( e(ilog) \): iteration log (up to 20 iterations)
- \( e(gradient) \): gradient vector
- \( e(V) \): variance–covariance matrix of the estimators
- \( e(V_modelbased) \): model-based variance

**Functions**
- \( e(sample) \): marks estimation sample
Methods and formulas

The heteroskedastic probit model is a generalization of the probit model because it allows the scale of the inverse link function to vary from observation to observation as a function of the independent variables.

The log-likelihood function for the heteroskedastic probit model is

\[
\ln L = \sum_{j \in S} w_j \ln \Phi \left\{ \frac{x_j \beta}{\exp(z\gamma)} \right\} + \sum_{j \not\in S} w_j \ln \left[ 1 - \Phi \left\{ \frac{x_j \beta}{\exp(z\gamma)} \right\} \right]
\]

where \( S \) is the set of all observations \( j \) such that \( y_j \neq 0 \) and \( w_j \) denotes the optional weights. \( \ln L \) is maximized as described in [R] maximize.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using vce(robust) and vce(cluster clustvar), respectively. See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas.

hetprobit also supports estimation with survey data. For details on VCEs with survey data, see [SVY] variance estimation.

*forecast, hausman, and lrtest are not appropriate with svy estimation results.
predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, and standard deviations.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , statistic nooffset]
predict [type] { stub* | newvar_{reg newvar_{insigma2} } [if] [in] , scores
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>probability of a positive outcome; the default</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>sigma</td>
<td>standard deviation of the error term</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample: type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Options for predict

- `pr`, the default, calculates the probability of a positive outcome.
- `xb` calculates the linear prediction.
- `sigma` calculates the standard deviation of the error term.
- `nooffset` is relevant only if you specified `offset(varname)` for `hetprobit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $x_j \beta$ rather than as $x_j \beta + \text{offset}_j$.
- `scores` calculates equation-level score variables.
  - The first new variable will contain $\partial \ln L / \partial (x_j \beta)$.
  - The second new variable will contain $\partial \ln L / \partial (z_j \gamma)$.
margins

Description for margins

margins estimates margins of response for probabilities, linear predictions, and standard deviations.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [ predict(statistic ...) ... ] [ options ]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>probability of a positive outcome; the default</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>sigma</td>
<td>standard deviation of the error term</td>
</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.

Remarks and examples

Once you have fit a model, you can use the predict command to obtain the predicted probabilities for both the estimation sample and other samples; see [U] 20 Estimation and postestimation commands and [R] predict. predict without arguments calculates the predicted probability of a positive outcome. With the xb option, predict calculates the index function combination, \( x_j b \), where \( x_j \) are the independent variables in the \( j \)th observation and \( b \) is the estimated parameter vector. With the sigma option, predict calculates the predicted standard deviation, \( \sigma_j = \exp(z_j \gamma) \).
Example 1

We use `predict` to compute the predicted probabilities and standard deviations based on the model in example 2 in [R] `hetprobit` to compare these with the actual values:

```
.predict phat
(option pr assumed; Pr(y))
.generate diff_p = phat - p
.summarize diff_p
```

```
Variable |     Obs     |     Mean     |     Std. Dev.     |      Min     |       Max
---------|------------|--------------|-------------------|-------------|-------------
diff_p   |     1,000  |   .0082805   |   .0103027      |  -.0169849  |     .0396469
```

```
.predict sigmahat, sigma
.generate diff_s = sigmahat - sigma
.summarize diff_s
```

```
Variable |     Obs     |     Mean     |     Std. Dev.     |      Min     |       Max
---------|------------|--------------|-------------------|-------------|-------------
diff_s   |     1,000  |  -.2579493   |     .2126614    |  -.7661171  |     -.000025
```

[R] `hetprobit` — Heteroskedastic probit model

[U] 20 Estimation and postestimation commands
Describing histogram draws histograms of \textit{varname}, which is assumed to be the name of a continuous variable unless the \texttt{discrete} option is specified.

**Quick start**

Histogram of \texttt{v1}
\begin{verbatim}
    histogram v1
\end{verbatim}

Add a normal density curve to the graph
\begin{verbatim}
    histogram v1, normal
\end{verbatim}

Add a kernel density estimate to the graph
\begin{verbatim}
    histogram v1, normal kdensity
\end{verbatim}

Add “My Title” as the title of the graph
\begin{verbatim}
    histogram v1, normal kdensity title("My Title")
\end{verbatim}

Specify the number of bins as 10
\begin{verbatim}
    histogram v1, bin(10)
\end{verbatim}

Specify the width of the bins as 2
\begin{verbatim}
    histogram v1, width(2)
\end{verbatim}

Specify that \texttt{v2} should be treated as discrete
\begin{verbatim}
    histogram v2, discrete
\end{verbatim}

As above, but with narrower bars and space between the bars
\begin{verbatim}
    histogram v2, discrete barwidth(.8)
\end{verbatim}

Add labels to the bars on the \textit{x} axis
\begin{verbatim}
    histogram v2, discrete barwidth(.8) xlabel(1 "Category 1" ///
        2 "Category 2" 3 "Category 3" 4 "Category 4")
\end{verbatim}

Show frequencies on the \textit{y} axis
\begin{verbatim}
    histogram v1, frequency
\end{verbatim}

Show percentages on the \textit{y} axis
\begin{verbatim}
    histogram v1, percent
\end{verbatim}

Produce histograms for each value of categorical variable \texttt{catvar}
\begin{verbatim}
    histogram v1, by(catvar)
\end{verbatim}

As above, but with histograms arranged in a single column
\begin{verbatim}
    histogram v1, by(cvar, cols(1))
\end{verbatim}

Density plots

- `normal` | add a normal density to the graph
- `normopts(line_options)` | affect rendition of normal density
- `kdensity` | add a kernel density estimate to the graph
- `kdenopts(kdensity_options)` | affect rendition of kernel density

Add plots

- `addplot(plot)` | add other plots to the histogram

Y axis, X axis, Titles, Legend, Overall, By

- `twoway_options` | any options documented in [G-3] `twoway_options`

fweights are allowed; see [U] 11.1.6 weight.
Options for use in the continuous case

\textbf{Main}

\texttt{bin(\#)} and \texttt{width(\#)} are alternatives. They specify how the data are to be aggregated into bins: \texttt{bin()} by specifying the number of bins (from which the width can be derived) and \texttt{width()} by specifying the bin width (from which the number of bins can be derived).

If neither option is specified, results are the same as if \texttt{bin(k)} had been specified, where

$$k = \min\{\sqrt{N}, 10 \ln(N)/\ln(10)\}$$

and where \(N\) is the (weighted) number of observations.

\texttt{start(\#)} specifies the theoretical minimum of \texttt{varname}. The default is \texttt{start(m)}, where \(m\) is the observed minimum value of \texttt{varname}.

Specify \texttt{start()} when you are concerned about sparse data, for instance, if you know that \texttt{varname} can have a value of 0, but you are concerned that 0 may not be observed.

\texttt{start(\#)}, if specified, must be less than or equal to \(m\), or else an error will be issued.

Options for use in the discrete case

\textbf{Main}

\texttt{discrete} specifies that \texttt{varname} is discrete and that you want each unique value of \texttt{varname} to have its own bin (bar of histogram).

\texttt{width(\#)} is rarely specified in the discrete case; it specifies the width of the bins. The default is \texttt{width(d)}, where \(d\) is the observed minimum difference between the unique values of \texttt{varname}.

Specify \texttt{width()} if you are concerned that your data are sparse. For example, in theory \texttt{varname} could take on the values, say, 1, 2, 3, ..., 9, but because of the sparseness, perhaps only the values 2, 4, 7, and 8 are observed. Here the default width calculation would produce \texttt{width(2)}, and you would want to specify \texttt{width(1)}.

\texttt{start(\#)} is also rarely specified in the discrete case; it specifies the theoretical minimum value of \texttt{varname}. The default is \texttt{start(m)}, where \(m\) is the observed minimum value.

As with \texttt{width()}, specify \texttt{start(\#)} if you are concerned that your data are sparse. In the previous example, you might also want to specify \texttt{start(1)}. \texttt{start()} does nothing more than add white space to the left side of the graph.

The value of \# in \texttt{start()} must be less than or equal to \(m\), or an error will be issued.

Options for use in the continuous and discrete cases

\textbf{Main}

density, fraction, frequency, and percent specify whether you want the histogram scaled to density units, fractional units, frequencies, or percentages. density is the default.

density scales the height of the bars so that the sum of their areas equals 1.

fraction scales the height of the bars so that the sum of their heights equals 1.
frequency scales the height of the bars so that each bar’s height is equal to the number of
observations in the category. Thus the sum of the heights is equal to the total number of
observations.

percent scales the height of the bars so that the sum of their heights equals 100.

**bar_options** are any of the options allowed by `graph twoway bar`; see [G-2] *graph twoway bar*.

One of the most useful **bar_options** is `barwidth(#)`, which specifies the width of the bars in
`varname` units. By default, `histogram` draws the bars so that adjacent bars just touch. If you want
gaps between the bars, do not specify `histogram`’s `width()` option—which would change how
the histogram is calculated—but specify the **bar_option** `barwidth()` or the `histogram` option
gap, both of which affect only how the bar is rendered.

The **bar_option** `horizontal` cannot be used with the `addlabels` option.

`binrescale` specifies that bin size and plot range be recalculated for each group when `by()` is
specified. If `normal` is specified, the mean and standard deviation of each overlaid normal density
plot are recalculated in each group. Similarly, if `kdensity` is specified, the scaling of the overlaid
kernel density plot is recalculated in each group.

`addlabels` specifies that the top of each bar be labeled with the density, fraction, or frequency, as
determined by the `density`, `fraction`, and `frequency` options.

`addlabopts(marker_label_options)` specifies how to render the labels atop the bars. See
[G-3] *marker_label_options*. Do not specify the `marker_label_option` `mlabel(varname)`, which
specifies the variable to be used; this is specified for you by `histogram`.

`addlabopts()` will accept more options than those documented in [G-3] *marker_label_options*.
All options allowed by `twoway scatter` are also allowed by `addlabopts()`; see [G-2] *graph twoway scatter*. One particularly useful option is `yvarformat();` see [G-3] *advanced_options*.

**Density plots**

`normal` specifies that the histogram be overlaid with an appropriately scaled normal density. The
normal will have the same mean and standard deviation as the data.

`normopts(line_options)` specifies details about the rendition of the normal curve, such as the color
and style of line used. See [G-2] *graph twoway line*.

`kdensity` specifies that the histogram be overlaid with an appropriately scaled kernel density estimate
of the density. By default, the estimate will be produced using the Epanechnikov kernel with an
“optimal” half-width. This default corresponds to the default of `kdensity`; see [R] *kdensity*. How
the estimate is produced can be controlled using the `kdenopts()` option described below.

`kdenopts(kdensity_options)` specifies details about how the kernel density estimate is to be produced
along with details about the rendition of the resulting curve, such as the color and style of line used.
The kernel density estimate is described in [G-2] *graph twoway kdensity*. As an example,
if you wanted to produce kernel density estimates by using the Gaussian kernel with optimal
half-width, you would specify `kdenopts(gauss)` and if you also wanted a half-width of 5, you
would specify `kdenopts(gauss width(5))`.

**Add plots**

`addplot(plot)` allows adding more `graph twoway` plots to the graph; see [G-3] *addplot_option*. 
Y axis, X axis, Titles, Legend, Overall, By

twoway_options are any of the options documented in [G-3] twoway_options. This includes, most importantly, options for titling the graph (see [G-3] title_options), options for saving the graph to disk (see [G-3] saving_option), and the by() option, which will allow you to simultaneously graph histograms for different subsets of the data (see [G-3] by_option).

Remarks and examples

Remarks are presented under the following headings:

Histograms of continuous variables
Overlaying normal and kernel density estimates
Histograms of discrete variables
Use with by()
Video example

For an example of editing a histogram with the Graph Editor, see Pollock (2011, 29–31).

Histograms of continuous variables

histogram assumes that the variable is continuous, so you need type only histogram followed by the variable name:

. use http://www.stata-press.com/data/r14/sp500
(S&P 500)
. histogram volume
(bin=15, start=4103, width=1280.3533)

The small values reported for density on the y axis are correct; if you added up the area of the bars, you would get 1. Nevertheless, many people are used to seeing histograms scaled so that the bar heights sum to 1,
and others are used to seeing histograms so that the bar height reflects the number of observations,

```
. histogram volume, frequency
(bin=15, start=4103, width=1280.3533)
```

Regardless of the scale you prefer, you can specify other options to make the graph look more impressive:
. summarize volume
  Variable | Obs | Mean  | Std. Dev. | Min | Max
  volume   | 248 | 12320.68 | 2585.929 | 4103 | 23308.3

. histogram volume, freq
  > xaxis(1 2)
  > ylabel(0(10)60, grid)
  > xlabel(12321 "mean"
  > 9735 "-1 s.d."
  > 14907 "+1 s.d."
  > 7149 "-2 s.d."
  > 17493 "+2 s.d."
  > 20078 "+3 s.d."
  > 22664 "+4 s.d."
  > , axis(2) grid gmax)
  > xtitle("", axis(2))
  > subtitle("S&P 500, January 2001 - December 2001")
  > note("Source: Yahoo! Finance and Commodity Systems, Inc.")

For an explanation of the xaxis() option—it created the upper and lower $x$ axis—see [G-3] axis_choice_options. For an explanation of the ylabel() and xlabel() options, see [G-3] axis_label_options. For an explanation of the subtitle() and note() options, see [G-3] title_options.

**Overlaying normal and kernel density estimates**

Specifying normal will overlay a normal density over the histogram. It would be enough to type

```
. histogram volume, normal
```

but we will add the option to our more impressive rendition:

```
. summarize volume
  Variable | Obs | Mean  | Std. Dev. | Min | Max
  volume   | 248 | 12320.68 | 2585.929 | 4103 | 23308.3
```
If we instead wanted to overlay a kernel density estimate, we could specify `kdensity` in place of `normal`.

**Histograms of discrete variables**

Specify `histogram`'s discrete option when you wish to treat the data as discrete—when you wish each unique value of the variable to be assigned its own bin. For instance, in the automobile data, `mpg` is a continuous variable, but the mileage ratings have been measured to integer precision. If we were to type

```
  . use http://www.stata-press.com/data/r14/auto
  (1978 Automobile Data)
  . histogram mpg
```

`mpg` would be treated as continuous and categorized into eight bins by the default number-of-bins calculation, which is based on the number of observations, 74.
Adding the `discrete` option makes a histogram with a bin for each of the 21 unique values.

```
. histogram mpg, discrete
  (start=12, width=1)
```

Just as in the continuous case, the $y$ axis was reported in density, and we could specify the `fraction` or `frequency` options if we wanted it to be reported differently. Below we specify `frequency`, we specify `addlabels` to add a report of frequencies printed above the bars, we specify `ylabel(,grid)` to add horizontal grid lines, and we specify `xlabel(12(2)42)` to label the values 12, 14, ..., 42 on the $x$ axis:

```
. histogram mpg, discrete freq addlabels ylabel(,grid) xlabel(12(2)42)
  (start=12, width=1)
```
histogram — Histograms for continuous and categorical variables

Use with by()

histogram may be used with graph twoway’s by(); for example,

. use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
. histogram mpg, discrete by(foreign)

![Histograms for Domestic and Foreign Mileage](image)

Here results would be easier to compare if the graphs were presented in one column:

. histogram mpg, discrete by(foreign, col(1))

![Histograms in One Column](image)

col(1) is a by() suboption—see [G-3] by_option—and there are other useful suboptions, such as total, which will add an overall total histogram. total is a suboption of by(), not an option of histogram, so you would type

. histogram mpg, discrete by(foreign, total)

and not histogram mpg, discrete by(foreign) total.

```
. use http://www.stata-press.com/data/r14/voter
. histogram candi [freq=pop], discrete fraction by(inc, total)
  > gap(40) xlabel(2 3 4, valuelabel)
```

![Histogram of candidate votes by income](image)

We specified `gap(40)` to reduce the width of the bars by 40%. We also used `xlabel()`’s `valuelabel` suboption, which caused our bars to be labeled “Clinton”, “Bush”, and “Perot”, rather than 2, 3, and 4; see [G-3] `axis_label_options`.

**Description**

\texttt{icc} estimates intraclass correlations for one-way random-effects models, two-way random-effects models, or two-way mixed-effects models for both individual and average measurements. Intraclass correlations measuring consistency of agreement or absolute agreement of the measurements may be estimated.

**Quick start**

Individual and average absolute-agreement intraclass correlation coefficients (ICCs) for ratings $y$ of targets identified by $\text{tid}$ in a one-way random-effects model

\begin{verbatim}
icc y tid
\end{verbatim}

As above, but test that the individual and average ICCs are equal to 0.5

\begin{verbatim}
icc y tid, testvalue(.5)
\end{verbatim}

Absolute-agreement ICCs for targets identified by $\text{tid}$ and raters identified by $\text{rid}$ in a two-way random-effects model

\begin{verbatim}
icc y tid rid
\end{verbatim}

As above, but estimate consistency-of-agreement ICCs

\begin{verbatim}
icc y tid rid, consistency
\end{verbatim}

Consistency-of-agreement ICCs when estimating random effects for targets and fixed effects for raters in a mixed-effects model

\begin{verbatim}
icc y tid rid, mixed
\end{verbatim}

As above, but estimate absolute-agreement ICCs

\begin{verbatim}
icc y tid rid, mixed absolute
\end{verbatim}

As above, but report 90\% confidence intervals and test that ICCs are equal to 0.3

\begin{verbatim}
icc y tid rid, mixed absolute level(90) testvalue(.3)
\end{verbatim}

* mixed is required.

bootstrap, by, jackknife, and statsby are allowed; see [U] 11.1.10 Prefix commands.

**Options for one-way RE model**

- **Main**
  - absolute specifies that intraclass correlations measuring absolute agreement of the measurements be estimated. This is the default for random-effects models.
  - testvalue(#) tests whether intraclass correlations equal #. The default is testvalue(0).

- **Reporting**
  - level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [R] level.
  - format(%,fmt) specifies how the intraclass correlation estimates and confidence intervals are to be formatted. The default is format(%9.0g).

**Options for two-way RE and ME models**

- **Main**
  - mixed is required to calculate two-way mixed-effects models. mixed specifies that intraclass correlations for a mixed-effects model be estimated.
  - absolute specifies that intraclass correlations measuring absolute agreement of the measurements be estimated. This is the default for random-effects models. Only one of absolute or consistency may be specified.
  - consistency specifies that intraclass correlations measuring consistency of agreement of the measurements be estimated. This is the default for mixed-effects models. Only one of absolute or consistency may be specified.
  - testvalue(#) tests whether intraclass correlations equal #. The default is testvalue(0).
icc — Intraclass correlation coefficients

```plaintext
level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is
level(95) or as set by set level; see [R] level.

format(%,fmt) specifies how the intraclass correlation estimates and confidence intervals are to be
formatted. The default is format(%,9.0g).

- Two-way random effects
- Two-way mixed effects
- Adoption study
- Relationship between ICCs
- Tests against nonzero values

Introduction

In some disciplines, such as psychology and sociology, data are often measured with error that
can seriously affect statistical interpretation of the results. Thus it is important to assess the amount
of measurement error by evaluating the consistency or reliability of measurements. The intraclass
correlation coefficient (ICC) is often used to measure the consistency or homogeneity of measurements.

Several versions of ICCs are introduced in the literature depending on the experimental design and
goals of the study (see, for example, Shrout and Fleiss [1979] and McGraw and Wong [1996a]).
Following Shrout and Fleiss (1979), we describe various forms of ICCs in the context of a reliability
study of ratings of different targets (or objects of measurements) by several raters.

Consider \( n \) targets (for example, students, patients, athletes) that are randomly sampled from a
population of interest. Each target is rated independently by a set of \( k \) raters (for example, teachers,
doctors, judges). One rating per target and rater is obtained. It is of interest to determine the extent
of the agreement of the ratings.

As noted by Shrout and Fleiss (1979) and McGraw and Wong (1996a), you need to answer several
questions to decide what version of ICC is appropriate to measure the agreement in your study:

1. Is a one-way or two-way analysis-of-variance model appropriate for your study?
2. Are differences between raters’ mean ratings relevant to the reliability of interest?
3. Is the unit of analysis an individual rating or the mean rating over several raters?
4. Is the consistency of agreement or the absolute agreement of ratings of interest?

Three types of analysis-of-variance models are considered for the reliability study: one-way random
effects, two-way random effects, and two-way mixed effects. Mixed models contain both fixed effects
and random effects. In the one-way random-effects model, each target is rated by a different set of \( k \)
independent raters, who are randomly drawn from the population of raters. The target is the only
random effect in this model; the effects due to raters and possibly due to rater-and-target interaction
cannot be separated from random error. In the two-way random-effects model, each target is rated
by the same set of \( k \) independent raters, who are randomly drawn from the population of raters.
The random effects in this model are target and rater and possibly their interaction, although in the
absence of repeated measurements for each rater on each target, the effect of an interaction cannot
be separated from random error. In the two-way mixed-effects model, each target is rated by the
same set of \( k \) independent raters. Because they are the only raters of interest, rater is a fixed effect. The random effects are target and possibly target-and-rater interaction, but again the interaction effect cannot be separated from random error without repeated measurements for each rater and target. The definition of ICC depends on the chosen random-effects model; see Methods and formulas for details.

In summary, use a one-way model if there are no systematic differences in measurements due to raters and use a two-way model otherwise. If you want to generalize your results to a population of raters from which the observed raters are sampled, use a two-way random-effects model, treating raters as random. If you are only interested in the effects of the observed \( k \) raters, use a two-way mixed-effects model, treating raters as fixed. For example, suppose you compare judges’ ratings of targets from different groups. If you use the combined data from \( k \) judges to compare the groups, the random-effects model is appropriate. If you compare groups separately for each judge and then pool the differences, the mixed-effects model is appropriate.

The definition of ICC also depends on the unit of analysis in a study—whether the agreement is measured between individual ratings (individual ICC) or between the averages of ratings over several raters (average ICC). The data on individual ratings are more common. The data on average ratings are typically used when individual ratings are deemed unreliable. The average ICC can also be used when teams of raters are used to rate a target. For example, the ratings of teams of physicians may be evaluated in this manner. When the unit of analysis is an average rating, you should remember that the interpretation of ICC pertains to average ratings and not individual ratings.

Finally, depending on whether consistency of agreement or absolute agreement is of interest, two types of ICC are used: consistency-of-agreement ICC (CA-ICC) and absolute-agreement ICC (AA-ICC). Under consistency of agreement, the scores are considered consistent if the scores from any two raters differ by the same constant value for all targets. This implies that raters give the same ranking to all targets. Under absolute agreement, the scores are considered in absolute agreement if the scores from all raters match exactly.

For example, suppose we observe three targets and two raters. The ratings are (2,4), (4,6), and (6,8), with rater 1 giving the scores (2,4,6) and rater 2 giving the scores (4,6,8), two points higher than rater 1. The CA-ICC between individual ratings is 1 because the scores from rater 1 and rater 2 differ by a constant value (two points) for all targets. That rater 1 gives lower scores than rater 2 is deemed irrelevant under the consistency measure of agreement. The raters have the same difference of opinion on every target, and the variation between raters that is caused by this difference is not relevant. On the other hand, the AA-ICC between individual ratings is \( \frac{8}{12} = 0.67 \), where 8 is the estimated between-target variance and 12 is the estimated total variance of ratings.

Either CA-ICC or AA-ICC can serve as a useful measure of agreement depending on whether rater variability is relevant for determining the degree of agreement. As McGraw and Wong (1996a) point out, CA-ICC is useful when comparative judgments are made about objects of measurement. The CA-ICC represents correlation when the rater is fixed; the AA-ICC represents correlation when the rater is random.

See Shrout and Fleiss (1979) and McGraw and Wong (1996a) for more detailed guidelines about the choice of appropriate ICC.

Shrout and Fleiss (1979) and McGraw and Wong (1996a) describe 10 versions of ICCs based on the concepts above: individual and average AA-ICCs for a one-way model (consistency of agreement is not defined for this model); individual and average AA-ICCs and CA-ICCs for a two-way random-effects model; and individual and average AA-ICCs and CA-ICCs for a two-way mixed-effects model. Although each of these ICCs has its own definition and interpretation, the estimators for some are identical, leading to the same estimates of those ICCs; see Relationship between ICCs and Methods and formulas for details.
The `icc` command calculates ICCs for each of the three analysis-of-variance models. You can use option `absolute` to compute AA-ICCs or option `consistency` to compute CA-ICCs. By default, `icc` computes ICCs corresponding to the correlation between ratings and between average ratings made on the same target: AA-ICC for a random-effects model and CA-ICC for a mixed-effects model. As pointed out by Shrout and Fleiss (1979), although the data on average ratings might be needed for reliability, the generalization of interest might be individuals. For this reason, `icc` reports ICCs for both units, individual and average, for each model.

In addition to estimates of ICCs, `icc` provides confidence intervals and one-sided $F$ tests. The $F$ test of $H_0: \rho = 0$ versus $H_a: \rho > 0$ is the same for the individual and average ICCs, so `icc` reports one test. This is not true, however, for nonzero null hypotheses (see Tests against nonzero values for details), so `icc` reports a separate test in this case.

The `icc` command requires data in long form; see `[D] reshape` for how to convert data in wide form to long form. The data must also be balanced and contain one observation per target and rater. For unbalanced data, `icc` omits all targets with fewer than $k$ ratings from computation. Under one-way models, $k$ is determined as the largest number of observed ratings for a target. Under two-way models, $k$ is the number of unique raters. If multiple observations per target and rater are detected, `icc` issues an error.

We demonstrate the use of `icc` using datasets from Shrout and Fleiss (1979) and McGraw and Wong (1996a). In the next three sections, we use an example from table 2 of Shrout and Fleiss (1979) with six targets and four judges. For instructional purposes, we analyze these data under each of the three different models: one-way random effects, two-way random effects, and two-way mixed effects.

### One-way random effects

In the one-way random-effects model, we assume that the $n$ targets being rated are randomly selected from the population of potential targets. Each is rated by a different set of $k$ raters randomly drawn from the population of potential raters. McGraw and Wong (1996a) describe an example of this setting, where behavioral genetics data are used to assess familial resemblance. Family units can be viewed as “targets”, and children can be viewed as “raters”. By taking a measurement on a child of the family unit, we obtain the “rating” of the family unit by the “child-rater”. In this case, we can use ICC to assess similarity between children within a family or, in other words, assess if there is a family effect in these data.

As we mentioned in the introduction, only AA-ICC is defined for a one-way model. The consistency of agreement is not defined in this case, as each target is evaluated by a different set of raters. Thus there is no between-rater variability in this model.

In a one-way model, the AA-ICC corresponds to the correlation coefficient between ratings within a target. It is also a ratio of the between-target variance of ratings to the total variance of ratings, the sum of the between-target and error variances.

#### Example 1: One-way random-effects ICCs

Consider data from table 2 of Shrout and Fleiss (1979) stored in `judges.dta`. The data contain 24 ratings of $n = 6$ targets by $k = 4$ judges. We list the first eight observations:
For a moment, let’s ignore that targets are rated by the same set of judges. Instead, we assume that a different set of four judges is used to rate each target. In this case, the only systematic variation in the data is due to targets, so the one-way random-effects model is appropriate.

We use `icc` to estimate the intraclass correlations for these data. To compute ICCs for a one-way model, we specify the dependent variable `rating` followed by the target variable `target`:

```
. icc rating target
```

### Intraclass correlations

#### One-way random-effects model

<table>
<thead>
<tr>
<th>Target</th>
<th>Rating</th>
<th>Judge</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>9</td>
<td>1</td>
</tr>
<tr>
<td>2.</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3.</td>

<tr>
<td>8.</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>

The estimated correlation between individual ratings is 0.17, indicating little similarity between ratings within a target, low reliability of individual target ratings, or no target effect. The estimated intraclass correlation between ratings averaged over \( k = 4 \) judges is higher, 0.44. (The average ICC will typically be higher than the individual ICC.) The estimated intraclass correlation measures the similarity or reliability of mean ratings from groups of four judges. We do not have statistical evidence that either ICC is different from zero based on reported confidence intervals and the one-sided \( F \) test.

Note that although the estimates of ICCs cannot be negative in this setting, the lower bound of the computed confidence interval may be negative. A common ad-hoc way of handling this is to truncate the lower bound at zero.

The estimates of both the individual and the average AA-ICC are also computed by the `loneway` command (see [R] `loneway`), which performs a one-way analysis of variance.
Technical note

Mean rating is commonly used when individual rating is unreliable because the reliability of a mean rating is always higher than the reliability of the individual rating when the individual reliability is positive.

In the previous example, we estimated low reliability of the individual ratings of a target, 0.17. The reliability increased to 0.44 for the ratings averaged over four judges. What if we had more judges?

We can use the Spearman–Brown formula (Spearman 1910; Brown 1910) to compute the \( m \)-average ICC based on the individual ICC:

\[
\text{ICC}(m) = \frac{m \text{ICC}(1)}{1 + (m - 1) \text{ICC}(1)}
\]

Using this formula for the previous example, we find that the mean reliability over, say, 10 judges is \( 10 \times 0.17 / (1 + 9 \times 0.17) = 0.67 \).

Alternatively, we can invert the Spearman–Brown formula to determine the number of judges (or the number of ratings of a target) we need to achieve the desired reliability. Suppose we would like an average reliability of 0.9, then

\[
m = \frac{\text{ICC}(m) \{(1 - \text{ICC}(1))\}}{\text{ICC}(1) \{(1 - \text{ICC}(m))\}} = \frac{0.9(1 - 0.17)}{0.17(1 - 0.9)} = 44
\]

See, for example, Bliese (2000) for other examples.

Two-way random effects

As before, we assume that the targets being rated are randomly selected from the population of potential targets. We now also assume that each target is evaluated by the same set of \( k \) raters, who have been randomly sampled from the population of raters. In this scenario, we want to generalize our findings to the population of raters from which the observed \( k \) raters were sampled. For example, suppose we want to estimate the reliability of doctors’ evaluations of patients with a certain condition. Unless the reliability at a specific hospital is of interest, the doctors may be interchanged with others in the relevant population of doctors.

As for a one-way model, the AA-ICC corresponds to the correlation between measurements on the same target and is also a ratio of the between-target variance to the total variance of measurements in a two-way random-effects model. The total variance is now the sum of the between-target, between-rater, and error variances. Unlike a one-way model, the CA-ICC can be computed for a two-way random-effects model when the consistency of agreement is of interest rather than the absolute agreement. The CA-ICC is also the ratio of the between-target variance to the total variance, but the total variance does not include the between-rater variance because the between-rater variability is irrelevant for the consistency of agreement.

Again, the two versions, individual and average, are available for each ICC.
Example 2: Two-way random-effects ICCs

Continuing with example 1, recall that we previously ignored that each target is rated by the same set of four judges and instead assumed different sets of judges. We return to the original data setting. We want to evaluate the agreement between judges’ ratings of targets in a population represented by the observed set of four judges.

In a two-way model, we must specify both the target and the rater variables. In icc, we now additionally specify the rater variable judge following the target variable target; the random-effects model is assumed by default.

```
.icc rating target judge
```

F test that ICC=0.00: F(5.0, 15.0) = 11.03  Prob > F = 0.000

Note: ICCs estimate correlations between individual measurements and between average measurements made on the same target.

As for a one-way random-effects model, icc by default reports AA-ICCs that correspond to the correlation between ratings on a target. Notice that both individual and average ICCs are larger in the two-way random-effects model than in the previous one-way model—0.29 versus 0.17 and 0.62 versus 0.44, respectively. We also have statistical evidence to reject the null hypothesis that neither ICC is zero based on confidence intervals and the F test. If a one-way model is used when a two-way model is appropriate, the true ICC will generally be underestimated.

Instead of the absolute agreement, we can also assess the consistency of agreement. The individual and average CA-ICCs are considered in McGraw and Wong (1996a) and denoted as ICC(C,1) and ICC(C,k), respectively. These ICCs are not considered in Shrout and Fleiss (1979) because they are not correlations in the strict sense. Although CA-ICCs do not estimate correlation, they can provide useful information about the reliability of the raters. McGraw and Wong (1996a) note that the practical value of the individual and average CA-ICCs in the two-way random-effects model setting is well documented in measurement theory, citing Hartmann (1982) and Suen (1988).
To estimate the individual and average CA-ICCs, we specify the consistency option:

```
.icc rating target judge, consistency
```

Intraclass correlations

</tr>
</tbody>
</table>

F test that ICC=0.00: F(5.0, 15.0) = 11.03 Prob > F = 0.000

We estimate that the consistency of agreement of ratings in the considered population of raters is high, 0.71, based on the individual CA-ICC. On the other hand, the absolute agreement of ratings is low, 0.29, based on the individual AA-ICC from the previous output.

The measure of consistency of agreement among means, the average CA-ICC, is equivalent to Cronbach’s alpha (Cronbach 1951); see [MV] alpha. The individual CA-ICC can also be equivalent to the Pearson’s correlation coefficient between raters when \( k = 2 \); see McGraw and Wong (1996a) for details.

In the next example, we will see that the actual estimates of the individual and average AA-ICCs and CA-ICCs are the same whether we examine a random-effects model or a mixed-effects model. The differences between these ICCs are in their definitions and interpretations.

**Two-way mixed effects**

As in a two-way random-effects model, we assume that the targets are randomly selected from the population of potential targets and that each is evaluated by the same set of \( k \) raters. In a mixed-effects model, however, we assume that these raters are the only raters of interest. So as before, the targets are random, but now the raters are fixed.

In the two-way mixed-effects model, the fixed effect of the rater does not contribute to the between-rater random variance component to the total variance. As such, the definitions and interpretations of ICCs are different in a mixed-effects model than in a random-effects model. However, the estimates of ICCs as well as test statistics and confidence intervals are the same. The only exceptions are average AA-ICCs and CA-ICCs. These are not estimable in a two-way mixed-effects model including an interaction term between target and rater; see Relationship between ICCs and Methods and formulas for details.

In a two-way mixed-effects model, the CA-ICC corresponds to the correlation between measurements on the same target. As pointed out by Shrout and Fleiss (1979), when the rater variance is ignored, the correlation coefficient is interpreted in terms of rater consistency rather than rater absolute agreement. Formally, the CA-ICC is the ratio of the covariance between measurements on the target to the total variance of the measurements. The AA-ICC corresponds to the same ratio, but includes a variance of the fixed factor, rater, in its denominator.
Example 3: Two-way mixed-effects ICCs

Continuing with example 2, suppose that we are now interested in assessing the agreement of ratings from only the observed four judges. The judges are now fixed effects, and the appropriate model is a two-way mixed-effects model.

To estimate ICCs for a two-way mixed-effects model, we specify the mixed option with icc:

```
. icc rating target judge, mixed
```

Intraclass correlations
Two-way mixed-effects model
Consistency of agreement

| Random effects: target | Number of targets = 6 |
| Fixed effects: judge  | Number of raters = 4  |

<table>

<td>.6756747 .9858917</td>
</tr>
</tbody>
</table>

F test that
ICC=0.00: F(5.0, 15.0) = 11.03 Prob > F = 0.000

Note: ICCs estimate correlations between individual measurements and between average measurements made on the same target.

As we described in the introduction, icc by default reports ICCs corresponding to the correlations. So, for a mixed-effects model, icc reports CA-ICC$s by default. The individual and average CA-ICC$s are denoted as ICC(3,1) and ICC(3,\( \bar{k} \)) in Shrout and Fleiss (1979) and ICC(\( C,1 \)) and ICC(\( C,\bar{k} \)) in McGraw and Wong (1996a).

Our estimates of the individual and average CA-ICC$s are identical to the CA-ICC estimates obtained under the two-way random-effects model in example 2, but our interpretation of the results is different. Under a mixed-effects model, 0.71 and 0.91 are the estimates, respectively, of the correlation between individual measurements and the correlation between average measurements made on the same target.

We can also estimate the AA-ICC$s in this setting by specifying the absolute option:

```
. icc rating target judge, mixed absolute
```

Intraclass correlations
Two-way mixed-effects model
Absolute agreement

| Random effects: target | Number of targets = 6 |
| Fixed effects: judge  | Number of raters = 4  |

<table>
<thead>
<tr>

<td>.2897638</td>
<td>.0187865 .7610844</td>
</tr>
<tr>
<td>Average</td>
<td>.6200505</td>
<td>.0711368 .927232</td>
</tr>
</tbody>
</table>

F test that
ICC=0.00: F(5.0, 15.0) = 11.03 Prob > F = 0.000

The intraclass correlation estimates match the individual and average AA-ICC$s obtained under the two-way random-effects model in example 2; but in a mixed-effects model, they do not represent correlations. We demonstrate the use of an individual AA-ICC in a mixed-effects setting in the next example.

The AA-ICC$s under a mixed-effects model are not considered by Shrout and Fleiss (1979). They are denoted as ICC(\( A,1 \)) and ICC(\( A,\bar{k} \)) in McGraw and Wong (1996a).
Adoption study

In this section, we consider the adoption study described in McGraw and Wong (1996a). Adoption studies commonly include two effects of interest. One is the mean difference between the adopted child and its biological parents. It is used to determine if characteristics of adopted children differ on average from those of their biological parents. Another effect of interest is the correlation between genetically paired individuals and genetically unrelated individuals who live together. This effect is used to evaluate the impact of genetic differences on individual differences.

As discussed in McGraw and Wong (1996a), a consistent finding from adoption research using IQ as a trait characteristic is that while adopted children typically have higher IQs than their biological parents, their IQs correlate better with those of their biological parents than with those of their adoptive parents. Both effects are important, and there is additional need to reconcile the two findings. McGraw and Wong (1996a) propose to use the individual AA-ICC for this purpose.

Example 4: Absolute-agreement ICC in a mixed-effects model

The adoption.dta dataset contains the data from table 6 of McGraw and Wong (1996a) on IQ scores:

```
. use http://www.stata-press.com/data/r14/adoption
(Biological mother and adopted child IQ scores)
. describe
Contains data from http://www.stata-press.com/data/r14/adoption.dta
obs: 20 Biological mother and adopted child IQ scores
vars: 5 15 May 2014 13:50
size: 160 (_dta has notes)

variable name storage display value variable label
      type format label
family  byte %9.0g Adoptive family ID
mc      byte %9.0g mcvalues 1=Mother, 2=Child
iq3     int %9.0g IQ scores, mother-child difference of 3 pts
iq9     int %9.0g IQ scores, mother-child difference of 9 pts
iq15    int %9.0g IQ scores, mother-child difference of 15 pts

Sorted by:
```

The `family` variable contains adoptive family identifiers, the `mc` variable records a mother or a child, and the `iq3`, `iq9`, and `iq15` variables record IQ scores with differences between mother and child mean IQ scores of 3, 9, and 15 points, respectively.
The variances of the mother and child IQ scores are the same.

Children are fixed effects, so the mixed-effects model is appropriate for these data. We want to compare individual CA-ICC with individual AA-ICC for each of the three IQ variables. We could issue a separate icc command for each of the three IQ variables to obtain the intraclass correlations. Instead, we use reshape to convert our data to long form with one iq variable and the new diff variable recording mean differences:

```
. reshape long iq, i(family mc) j(diff)
   (note: j = 3 9 15)
```

We can now use the by prefix with icc to estimate intraclass correlations for the three groups of interest:
. by diff, sort: icc iq family mc, mixed

-> diff = 3
Intraclass correlations
Two-way mixed-effects model
Consistency of agreement
Random effects: family Number of targets = 10
Fixed effects: mc Number of raters = 2

Note: ICCs estimate correlations between individual measurements and between average measurements made on the same target.

-> diff = 15
(output omitted)

The estimated CA-ICCs are the same in all three groups and are equal to the corresponding estimates of the Pearson’s correlation coefficients because mothers’ and childrens’ IQ scores have the same variability. The scores differ only in means, and mean differences are irrelevant when measuring the consistency of agreement.
The AA-ICCs, however, differ across the three groups:

```
. by diff, sort: icc iq family mc, mixed absolute
```

-> diff = 3

As the mean differences increase, the AA-ICCs decrease. Their attenuation reflects the difference in means between biological mother and child IQs while still measuring their agreement. Notice that for small mean differences, the estimates of AA-ICCs and CA-ICCs are very similar.

Note that our estimates match those given in McGraw and Wong (1996b), who correct the original table 6 of McGraw and Wong (1996a).
Relationship between ICCs

In examples 2 and 3, we saw that the estimates of AA-ICCs and CA-ICCs are the same for two-way random-effects and two-way mixed-effects models. In this section, we consider the relationship between various forms of ICCs in more detail; also see Methods and formulas.

There are 10 different versions of ICCs, but only six different estimators are needed to compute them. These estimators include the two estimators for the individual and average AA-ICCs in a one-way model, the two estimators for the individual and average AA-ICCs in two-way models, and the two estimators for the individual and average CA-ICCs in two-way models.

Only individual and average AA-ICCs are defined for the one-way model. The estimates of AA-ICCs based on the one-way model will typically be smaller than individual and average estimates of AA-ICCs and CA-ICCs based on two-way models. The estimates of individual and average CA-ICCs will typically be larger than the estimates of individual and average AA-ICCs.

Although AA-ICCs and CA-ICCs have the same respective estimators in two-way random-effects and mixed-effects models, their definitions and interpretations are different. The AA-ICCs based on a random-effects model contain the between-rater variance component in the denominator of the variance ratio. The AA-ICCs based on a mixed-effects model contain the variance of the fixed-factor rater instead of the random between-rater variability. The AA-ICCs in a random-effects model represent correlations between any two measurements made on a target. The AA-ICCs in a mixed-effects model measure absolute agreement of measurements treating raters as fixed. The CA-ICCs for random-effects and mixed-effects models have the same definition but different interpretations. The CA-ICCs represent correlations between any two measurements made on a target in a mixed-effects model but estimate the degree of consistency among measurements treating raters as random in a random-effects model. The difference in the definitions of AA-ICCs and CA-ICCs is that CA-ICCs do not contain the between-rater variance in the denominator of the variance ratio.

For two-way models, the definitions and interpretations (but not the estimators) of ICCs also depend on whether the model contains an interaction between target and rater. For two-way models with interaction, ICCs include an additional variance component for the target-rater interaction in the denominator of the variance ratio. This component cannot be separated from random error because there is only one observation per target and rater.

Also, under a two-way mixed-effects model including interaction, the interaction components are not mutually independent, as they are in a two-way random-effects model. The considered version of the mixed-effects model places a constraint on the interaction effects—the sum of the interaction effects over levels of the fixed factor is zero; see, for example, chapter 7 in Kuehl (2000) for an introductory discussion of mixed models. In this version of the model, there is a correlation between the interaction effects. Specifically, the two interaction effects for the same target and two different raters are negatively correlated. As a result, the estimated intraclass correlation can be negative under a two-way mixed-effects model with interaction. Also, average AA-ICC and average CA-ICC cannot be estimated in a two-way mixed-effects model including interaction; see Methods and formulas and McGraw and Wong (1996a) for details.

Tests against nonzero values

It may be of interest to test whether the intraclass correlation is equal to a value other than zero. icc supports testing against positive values through the use of the testvalue() option. Specifying testvalue(#) provides a one-sided hypothesis test of $H_0: \rho = #$ versus $H_a: \rho > #$. The test is provided separately for both individual and average ICCs.
Example 5: Testing ICC against a nonzero value

We return to the two-way random-effects model for the judge and target data from Shrout and Fleiss (1979). Suppose we want to test whether the individual and average AA-ICCs are each equal to 0.2. We specify the `testvalue(0.2)` option with `icc`:

```
. use http://www.stata-press.com/data/r14/judges, clear
(Ratings of targets by judges)
. icc rating target judge, testvalue(0.2)
```

Intraclass correlations
Two-way random-effects model
Absolute agreement

<table>
<thead>
<tr>
<th>rating</th>
<th>ICC</th>
<th>[95% Conf. Interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Individual</td>
<td>.2897638</td>
<td>.0187865 .7610844</td>

</table>

F test that
ICC(1)=0.20: F(5.0, 5.3) = 1.54  Prob > F = 0.317
ICC(k)=0.20: F(5.0, 9.4) = 4.35  Prob > F = 0.026

Note: ICCs estimate correlations between individual measurements and between average measurements made on the same target.

We reject the null hypothesis that the average AA-ICC, labeled as ICC($k$) in the output, is equal to 0.2, but we do not have statistical evidence to reject the null hypothesis that the individual AA-ICC, labeled as ICC(1), is equal to 0.2.

Stored results

`icc` stores the following in `r()`:

Scalars
- `r(N_target)` number of targets
- `r(N_rater)` number of raters
- `r(icc_i)` intraclass correlation for individual measurements
- `r(icc_i_F)` F test statistic for individual ICC
- `r(icc_i_df1)` numerator degrees of freedom for `r(icc_i_F)`
- `r(icc_i_df2)` denominator degrees of freedom for `r(icc_i_F)`
- `r(icc_i_p)` p-value for F test of individual ICC
- `r(icc_i_lb)` lower endpoint for confidence intervals of individual ICC
- `r(icc_i_ub)` upper endpoint for confidence intervals of individual ICC
- `r(icc_avg)` intraclass correlation for average measurements
- `r(icc_avg_F)` F test statistic for average ICC
- `r(icc_avg_df1)` numerator degrees of freedom for `r(icc_avg_F)`
- `r(icc_avg_df2)` denominator degrees of freedom for `r(icc_avg_F)`
- `r(icc_avg_p)` p-value for F test of average ICC
- `r(icc_avg_lb)` lower endpoint for confidence intervals of average ICC
- `r(icc_avg_ub)` upper endpoint for confidence intervals of average ICC
- `r(testvalue)` null hypothesis value
- `r(level)` confidence level

Macros
- `r(model)` analysis-of-variance model
- `r(depvar)` name of dependent variable
- `r(target)` target variable
- `r(rater)` rater variable
- `r(type)` type of ICC estimated (absolute or consistency)
Methods and formulas

We observe $y_{ij}$, where $i = 1, \ldots, n$ and $j = 1, \ldots, k$. $y_{ij}$ is the $j$th rating on the $i$th target. Let $\alpha = 1 - l/100$, where $l$ is the significance level specified by the user.

Methods and formulas are presented under the following headings:

- Mean squares
- One-way random effects
- Two-way random effects
- Two-way mixed effects

Mean squares

The mean squares within targets are

$$WMS = \sum_i \sum_j \frac{(y_{ij} - \bar{y}_i)^2}{n(k - 1)}$$

where $\bar{y}_i = \sum_j y_{ij}/k$.

The mean squares between targets are

$$BMS = \sum_i \frac{(\bar{y}_i - \bar{y}_{..})^2}{n - 1}$$

where $\bar{y}_{..} = \sum_i \bar{y}_i/n$.

These are the only mean squares needed to estimate ICC in the one-way random-effects model. For the two-way models, we need two additional mean squares.

The mean squares between raters are

$$JMS = \sum_j \frac{(\bar{y}_{..j} - \bar{y}_{..})^2}{k - 1}$$

where $\bar{y}_{..j} = \sum_i y_{ij}/n$ and $\bar{y}_{..} = \sum_j \bar{y}_{..j}/k$.

The residual or error mean square is

$$EMS = \frac{\sum_i \sum_j (y_{ij} - \bar{y})^2 - (k - 1)JMS - (n - 1)BMS}{(n - 1)(k - 1)}$$
One-way random effects

Under the one-way random-effects model, we observe

$$y_{ij} = \mu + r_i + \epsilon_{ij} \quad \text{(M1)}$$

where $\mu$ is the mean rating, $r_i$ is the target random effect, and $\epsilon_{ij}$ is random error. The $r_i$s are i.i.d. $N(0, \sigma_r^2)$; $\epsilon_{ij}$s are i.i.d. $N(0, \sigma_\epsilon^2)$ and are independent of $r_i$s. There is no rater effect separate from the residual error because each target is evaluated by a different set of raters.

The individual AA-ICC is the correlation between individual measurements on the same target:

$$\rho_1 = \text{ICC}(1) = \text{Corr}(y_{ij}, y_{ij}') = \frac{\sigma_r^2}{\sigma_r^2 + \sigma_\epsilon^2}$$

The average AA-ICC is the correlation between average measurements of size $k$ made on the same target:

$$\rho_k = \text{ICC}(k) = \text{Corr}(\bar{y}_i, \bar{y}_i') = \frac{\sigma_r^2}{\sigma_r^2 + \sigma_\epsilon^2/k}$$

They are estimated by

$$\hat{\rho}_1 = \widehat{\text{ICC}}(1) = \frac{\text{BMS} - \text{WMS}}{\text{BMS} + (k - 1)\text{WMS}}$$

$$\hat{\rho}_k = \widehat{\text{ICC}}(k) = \frac{\text{BMS} - \text{WMS}}{\text{BMS}}$$

Confidence intervals. Let $F_{\text{obs}} = \text{BMS}/\text{WMS}$, let $F_l$ be the $(1 - \alpha/2) \times 100$th percentile of the $F_{n-1,n(k-1)}$ distribution, and let $F_u$ be the $(1 - \alpha/2) \times 100$th percentile of the $F_{n(k-1),n-1}$ distribution. Let $F_L = F_{\text{obs}}/F_l$ and $F_U = F_{\text{obs}}F_u$.

A $(1 - \alpha) \times 100\%$ confidence interval for $\rho_1$ is

$$\left( \frac{F_L - 1}{F_l + k - 1}, \frac{F_U - 1}{F_U + k - 1} \right) \quad (1)$$

A $(1 - \alpha) \times 100\%$ confidence interval for $\rho_k$ is

$$\left( 1 - \frac{1}{F_L}, 1 - \frac{1}{F_U} \right) \quad (2)$$

Hypothesis tests. Consider a one-sided hypothesis test of $H_0$: ICC = $\rho_0$ versus $H_a$: ICC > $\rho_0$.

The test statistic for $\rho_1$ is

$$F_{\rho_1} = \frac{\text{BMS}}{\text{WMS}} \frac{1 - \rho_0}{1 + (k - 1)\rho_0} \quad (3)$$

The test statistic for $\rho_k$ is

$$F_{\rho_k} = \frac{\text{BMS}}{\text{WMS}}(1 - \rho_0) \quad (4)$$

Under the null hypothesis, both $F_{\rho_1}$ and $F_{\rho_k}$ have the $F_{n-1,n(k-1)}$ distribution. When $\rho_0 = 0$, the two test statistics coincide.
### Two-way random effects

In this setting, the target is evaluated by the same set of raters, who are randomly drawn from the population of raters. The underlying models with and without interaction are

\[ y_{ij} = \mu + r_i + c_j + (rc)_{ij} + \epsilon_{ij} \quad (M2) \]

\[ y_{ij} = \mu + r_i + c_j + \epsilon_{ij} \quad (M2A) \]

where \( y_{ij} \) is the rating of the \( i \)th target by the \( j \)th rater, \( \mu \) is the mean rating, \( r_i \) is the target random effect, \( c_j \) is the rater random effect, \( (rc)_{ij} \) is the target-rater random effect, and \( \epsilon_{ij} \) is random error. The \( r_i \)s are i.i.d. \( N(0, \sigma^2_r) \), \( c_j \)s are i.i.d. \( N(0, \sigma^2_c) \), \( (rc)_{ij} \)s are i.i.d. \( N(0, \sigma^2_{rc}) \), and \( \epsilon_{ij} \)s are i.i.d. \( N(0, \sigma^2_\epsilon) \). Each effect is mutually independent of the others.

Below we provide formulas for ICCs for model (M2). The corresponding ICCs for model (M2A) can be obtained by setting \( \sigma^2_{rc} = 0 \).

The individual AA-ICC is the correlation between individual measurements on the same target:

\[ \rho_{A,1} = ICC(A,1) = \text{Corr}(y_{ij}, y_{ij'}) = \frac{\sigma^2_r}{\sigma^2_r + \sigma^2_c + (\sigma^2_{rc} + \sigma^2_\epsilon)} \]

The average AA-ICC is the correlation between average measurements of size \( k \) made on the same target:

\[ \rho_{A,k} = ICC(A,k) = \text{Corr}(\bar{y}_{i.}, \bar{y}_{i.'}) = \frac{\sigma^2_r}{\sigma^2_r + (\sigma^2_c + \sigma^2_{rc} + \sigma^2_\epsilon)/k} \]

The consistency-of-agreement intraclass correlation for individual measurements, individual CA-ICC, is

\[ \rho_{C,1} = ICC(C,1) = \frac{\sigma^2_r}{\sigma^2_r + (\sigma^2_{rc} + \sigma^2_\epsilon)} \]

The consistency-of-agreement intraclass correlation for average measurements of size \( k \), average CA-ICC, is

\[ \rho_{C,k} = ICC(C,k) = \frac{\sigma^2_r}{\sigma^2_r + (\sigma^2_{rc} + \sigma^2_\epsilon)/k} \]

With one observation per target and rater, \( \sigma^2_{rc} \) and \( \sigma^2_\epsilon \) cannot be estimated separately.
The estimators of intraclass correlations, confidence intervals, and test statistics are the same for models (M2) and (M2A). The estimators of ICCs are

\[
\hat{\rho}_{A,1} = \hat{\text{ICC}}(A,1) = \frac{\text{BMS} - \text{EMS}}{\text{BMS} + (k-1)\text{EMS} + \frac{k}{n} (\text{JMS} - \text{EMS})}
\]

\[
\hat{\rho}_{A,k} = \hat{\text{ICC}}(A,k) = \frac{\text{BMS} - \text{EMS}}{\text{BMS} + \frac{1}{n} (\text{JMS} - \text{EMS})}
\]

\[
\hat{\rho}_{C,1} = \hat{\text{ICC}}(C,1) = \frac{\text{BMS} - \text{EMS}}{\text{BMS} + (k-1)\text{EMS}}
\]

\[
\hat{\rho}_{C,k} = \hat{\text{ICC}}(C,k) = \frac{\text{BMS} - \text{EMS}}{\text{BMS}}
\]

**Confidence intervals.** Let \( a = k \hat{\rho}_{A,1} / \{n(1 - \hat{\rho}_{A,1})\} \), \( b = 1 + k \hat{\rho}_{A,1}(n-1) / \{n(1 - \hat{\rho}_{A,1})\} \), and

\[
v = \frac{(a \text{JMS} + b \text{EMS})^2}{\frac{a^2 \text{JMS}^2}{k-1} + \frac{b^2 \text{EMS}^2}{(n-1)(k-1)}}
\]

(5)

Let \( F_l \) be the \((1-\alpha/2)\) × 100th percentile of the \( F_{n-1,v} \) distribution and \( F_u \) be the \((1-\alpha/2)\) × 100th percentile of the \( F_{v,n-1} \) distribution.

A \((1-\alpha)\) × 100% confidence interval for \( \rho_{A,1} \) is given by \((L, U)\), where

\[
L = \frac{n(\text{BMS} - F_l \text{EMS})}{F_l \{k \text{JMS} + (kn - k - n) \text{EMS}\} + n \text{BMS}}
\]

\[
U = \frac{n(F_u \text{BMS} - \text{EMS})}{k \text{JMS} + (kn - k - n) \text{EMS} + n F_u \text{BMS}}
\]

(6)

A \((1-\alpha)\) × 100% confidence intervals for \( \rho_{A,k} \) is a special case of (6) with \( k = 1 \), where \( a = \hat{\rho}_{A,k} / \{n(1 - \hat{\rho}_{A,k})\} \), \( b = 1 + \hat{\rho}_{A,k}(n-1) / \{n(1 - \hat{\rho}_{A,k})\} \), and \( v \) is defined in (5).

To define confidence intervals for \( \rho_{C,1} \) and \( \rho_{C,k} \), let \( F_{\text{obs}} = \text{BMS}/\text{EMS} \), \( F_l \) be the \((1-\alpha/2)\) × 100th percentile of the \( F_{n-1,(n-1)(k-1)} \) distribution, and \( F_u \) be the \((1-\alpha/2)\) × 100th percentile of the \( F_{(n-1)(k-1),n-1} \) distribution. Let \( F_L = F_{\text{obs}}/F_l \) and \( F_L = F_{\text{obs}}F_u \).

A \((1-\alpha)\) × 100% confidence intervals for \( \rho_{C,1} \) and \( \rho_{C,k} \) are then as given by (1) and (2) for model (M1).

**Hypothesis tests.** Consider a one-sided hypothesis test of \( H_0: \text{ICC} = \rho_0 \) versus \( H_a: \text{ICC} > \rho_0 \). Let \( a = k \rho_0 / \{n(1 - \rho_0)\} \) and \( b = 1 + k \rho_0(n-1) / \{n(1 - \rho_0)\} \).

The test statistic for \( \rho_{A,1} \) is

\[
F_{\rho_{A,1}} = \frac{\text{BMS}}{a \text{JMS} + b \text{EMS}}
\]

Under the null hypothesis, \( F_{\rho_{A,1}} \) has the \( F_{n-1,v} \) distribution, where \( v \) is defined in (5).

The test statistic for \( \rho_{A,k} \) is defined similarly, except \( a = \rho_0 / \{n(1 - \rho_0)\} \) and \( b = 1 + \rho_0(n-1) / \{n(1 - \rho_0)\} \). Under the null hypothesis, \( F_{\rho_{A,k}} \) has the \( F_{n-1,v} \) distribution, where \( v \) is defined in (5). When \( \rho_0 = 0 \), then \( a = 0 \), \( b = 1 \), and the two test statistics coincide.

The test statistics for \( \rho_{C,1} \) and \( \rho_{C,k} \) are defined by (3) and (4), respectively, with WMS replaced by EMS. Under the null hypothesis, both \( F_{\rho_{C,1}} \) and \( F_{\rho_{C,k}} \) have the \( F_{n-1,(n-1)(k-1)} \) distribution. They also both have the same value when \( \rho_0 = 0 \).
Two-way mixed effects

In this setting, every target is evaluated by the same set of judges, who are the only judges of interest. The underlying models with and without interaction are

\[ y_{ij} = \mu + r_i + c_j + (rc)_{ij} + \epsilon_{ij} \]  

(M3)

\[ y_{ij} = \mu + r_i + c_j + \epsilon_{ij} \]  

(M3A)

where \( y_{ij} \) is the rating of the \( i \)th target by the \( j \)th rater, \( \mu \) is the mean rating, \( r_i \) is the target random effect, \( c_j \) is the rater random effect, \((rc)_{ij}\) is an interaction effect between target and rater, and \( \epsilon_{ij} \) is random error. The \( r_i \)s are i.i.d. \( \mathcal{N}(0, \sigma^2_r) \), \((rc)_{ij}\)s are \( \mathcal{N}(0, \sigma^2_{rc}) \), and \( \epsilon_{ij} \)s are i.i.d. \( \mathcal{N}(0, \sigma^2_\epsilon) \). Each random effect is mutually independent of the others. The \( c_j \)s are fixed such that \( \sum_j c_j = 0 \). The variance of \( c_j \)s is \( \theta^2_c = \sum_j c_j^2 / (k - 1) \).

In the presence of an interaction, two versions of a mixed-effects model may be considered. One assumes that \((rc)_{ij}\)s are i.i.d. \( \mathcal{N}(0, \sigma^2_{rc}) \). Another assumes that \((rc)_{ij}\)s are \( \mathcal{N}(0, \sigma^2_{rc}) \) with an additional constraint that \( \sum_j (rc)_{ij} = 0 \) (for example, Kuehl [2000]), so only interaction terms involving different targets are independent. The latter model is considered here.

We now define the intraclass correlations for individual measurements for model (M3).

The individual CA-ICC, the correlation between individual measurements on the same target, is

\[ \rho_{C,1} = \text{ICC}(C,1) = \text{Corr}(y_{ij}, y_{ij'}) = \frac{\sigma^2_r - \sigma^2_{rc}/(k - 1)}{\sigma^2_r + (\sigma^2_{rc} + \sigma^2_\epsilon)} \]

The absolute-agreement intraclass correlation for individual measurements, individual AA-ICC, is

\[ \rho_{A,1} = \text{ICC}(A,1) = \frac{\sigma^2_r - \sigma^2_{rc}/(k - 1)}{\sigma^2_r + \theta^2_c + (\sigma^2_{rc} + \sigma^2_\epsilon)} \]

Shrout and Fleiss (1979) show that the individual ICC could be negative in this case—a phenomenon first pointed out by Sitgreaves (1960). This can happen when the interaction term has a high variance relative to the targets and there are not many raters.

The individual intraclass correlations for model (M3A) have similar definitions with \( \sigma^2_{rc} = 0 \). The individual CA-ICC is the correlation between individual measurements on the same target, \( \text{Corr}(y_{ij}, y_{ij'}) \).

We now discuss the intraclass correlations that correspond to average measurements. Neither average AA-ICC, \( \rho_{A,k} \), nor average CA-ICC, \( \rho_{C,k} \), can be estimated under model (M3) (Shrout and Fleiss 1979; McGraw and Wong 1996a). The problem is that in this model, \( \sigma^2_r \), which is the covariance between two means based on \( k \) raters, cannot be estimated.

Specifically, the parameter \( \sigma^2_r \) appears only in the expectation of the between-target mean squares BMS. Under the restriction \( \sum_j (rc)_{ij} = 0 \),

\[ E(\text{BMS}) = k\sigma^2_r + \sigma^2_\epsilon \]

Note that \( \sigma^2_{rc} \) does not appear in the expectation of between-target mean squares. With one observation per target and rater, \( \sigma^2_{rc} \) and \( \sigma^2_\epsilon \) cannot be estimated separately (only their sum \( \sigma^2_{rc} + \sigma^2_\epsilon \) can be estimated), so BMS alone cannot be used to estimate \( \sigma^2_r \).
Under model (M3A), however, there is no interaction (and thus no interaction variance component $\sigma^2_{rc}$), so $\rho_{A,k}$ or $\rho_{C,k}$ can be estimated.

The average AA-ICC, the absolute-agreement intraclass correlation for average measurements of size $k$, is

$$\rho_{A,k} = \text{ICC}(A,k) = \frac{\sigma^2_{r}}{\sigma^2_{r} + (\theta^2_{c} + \sigma^2_{e})/k}$$

The average CA-ICC, the correlation between average measurements of size $k$ made on the same target, is

$$\rho_{C,k} = \text{ICC}(C,k) = \text{Corr}(\bar{y}_{i.}, \bar{y}'_{i.}) = \frac{\sigma^2_{r}}{\sigma^2_{r} + \sigma^2_{e}/k}$$

The estimators of ICCs, their confidence intervals, and hypothesis tests are as described for two-way random-effects models, except $\rho_{A,k}$ and $\rho_{C,k}$ are not defined under model (M3).

Remarks and examples

Stata does not have commands for inequality measures, except \texttt{roctab} has an option to report Gini and Pietra indices; see \cite{R_roctab}. Stata users, however, have developed an excellent suite of commands, many of which have been published in the \textit{Stata Journal} (SJ) and in the \textit{Stata Technical Bulletin} (STB).

Max Otto Lorenz (1876–1959) was born in Burlington, Iowa. He did his undergraduate studies at the University of Iowa and received his PhD from the University of Wisconsin-Madison in 1906. In 1905, he published his only article, “Methods of measuring the concentration of wealth”, in a scientific journal. In the article, he introduces what we now call the Lorenz curve, a term first introduced in a statistics textbook in 1912.

Lorenz worked all of his life in governmental statistical institutions. He was the Deputy Commissioner of Labor and Industrial Statistics for Wisconsin, worked for the U.S. Bureau of the Census and the Bureau of Railway Economics, and was the Director of the Bureau of Statistics and the Bureau of Transport and Economic Statistics.

His hobbies included calendar reform and Interlingua, a proposed international language.

References

intreg fits a model in which the dependent variable may be measured as point data, interval data, left-censored data, or right-censored data. As such, it is a generalization of the models fit by `tobit`. The dependent variable must be specified using two `depvars` that indicate how it was measured.

**Quick start**

Regression on x1 and x2 of an interval-measured dependent variable with lower endpoint `y_lower` and upper endpoint `y_upper`

```
intreg y_lower y_upper x1 x2
```

With robust standard errors

```
intreg y_lower y_upper x1 x2, vce(robust)
```

Model heteroskedasticity in the conditional variance as a function of x3

```
intreg y_lower y_upper x1 x2, het(x3)
```

Adjust for complex survey design using `svyset` data

```
svy: intreg y_lower y_upper x1 x2
```
Syntax

```plaintext
intreg depvar1 depvar2 [ indepvars ] [ if ] [ in ] [ weight ] [ , options ]
```

depvar1 and depvar2 should have the following form:

<table>
<thead>
<tr>
<th>Type of data</th>
<th>depvar1</th>
<th>depvar2</th>
</tr>
</thead>
<tbody>
<tr>
<td>point data</td>
<td>a = [a,a]</td>
<td>a</td>
</tr>
<tr>
<td>interval data</td>
<td>[a,b]</td>
<td>a</td>
</tr>
<tr>
<td>left-censored data</td>
<td>(−∞,b]</td>
<td>.</td>
</tr>
<tr>
<td>right-censored data</td>
<td>[a,+∞)</td>
<td>.</td>
</tr>
</tbody>
</table>

**options**

</table>

`indepvars` and `varlist` may contain factor variables; see [U] 11.4.3 Factor variables.
depvar1, depvar2, indepvars, and varlist may contain time-series operators; see [U] 11.4.4 Time-series varlists.
bootstrap, by, fp, jackknife, mfp, nestreg, rolling, statsby, stepwise, and svy are allowed; see [U] 11.1.10 Prefix commands.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
aweights are not allowed with the jackknife prefix; see [R] jackknife.
vce() and weights are not allowed with the svy prefix; see [SVY] svy.
aweights, fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
Options

*Model*

noconstant; see [R] estimation options.

het(varlist [, noconstant]) specifies that varlist be included in the specification of the conditional variance. This varlist enters the variance specification collectively as multiplicative heteroskedasticity.

offset(varname), constraints(constraints), collinear; see [R] estimation options.

*SE/Robust*

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

*Reporting*

level(#); see [R] estimation options.

nocnsreport; see [R] estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels,
allbaselevels,noflabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt),
sformat(%fmt), and nolstretch; see [R] estimation options.

*Maximization*

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace,
gradien, showstep, hessian, showtolerance, tolerance(#), ltolerance(#),
ntolerance(#), nonntolerance, and from(init_specs); see [R] maximize. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following option is available with intreg but is not shown in the dialog box:

coefflegend; see [R] estimation options.

Remarks and examples

intreg is a generalization of the models fit by tobit. Cameron and Trivedi (2010, 548–550) discuss the differences among censored, truncated, and interval data. If you know that the value for the \(j\)th individual is somewhere in the interval \([y_{1j}, y_{2j}]\), then the likelihood contribution from this individual is simply \(\Pr(y_{1j} \leq Y_j \leq y_{2j})\). For censored data, their likelihoods contain terms of the form \(\Pr(Y_j \leq y_j)\) for left-censored data and \(\Pr(Y_j \geq y_j)\) for right-censored data, where \(y_j\) is the observed censoring value and \(Y_j\) denotes the random variable representing the dependent variable in the model.

Hence, intreg can fit models for data where each observation represents interval data, left-censored data, right-censored data, or point data. Regardless of the type of observation, the data should be stored in the dataset as interval data; that is, two dependent variables, \(\text{depvar}_1\) and \(\text{depvar}_2\), are used to hold the endpoints of the interval. If the data are left-censored, the lower endpoint is \(-\infty\) and is represented by a missing value, ., or an extended missing value, .a, .b, ..., .z, in \(\text{depvar}_1\).
If the data are right-censored, the upper endpoint is $+\infty$ and is represented by a missing value, . (or an extended missing value), in `depvar2`. Point data are represented by the two endpoints being equal. Truly missing values of the dependent variable must be represented by missing values in both `depvar1` and `depvar2`.

Interval data arise naturally in many contexts, such as wage data. Often you know only that, for example, a person’s salary is between $30,000 and $40,000. Below we give an example for wage data and show how to set up `depvar1` and `depvar2`.

### Example 1

We have a dataset that contains the yearly wages of working women. Women were asked via a questionnaire to indicate a category for their yearly income from employment. The categories were less than 5,000, 5,001–10,000, ..., 25,001–30,000, 30,001–40,000, 40,001–50,000, and more than 50,000. The wage categories are stored in the `wagecat` variable.

```stata
use http://www.stata-press.com/data/r14/womenwage
(Wages of women)
tabulate wagecat
```

<table>
<thead>
<tr>
<th>Wage category ($1000s)</th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>14</td>
<td>2.87</td>
<td>2.87</td>
</tr>
<tr>
<td>10</td>
<td>83</td>
<td>17.01</td>
<td>19.88</td>
</tr>
<tr>
<td>15</td>
<td>158</td>
<td>32.38</td>
<td>52.25</td>
</tr>
<tr>
<td>20</td>
<td>107</td>
<td>21.93</td>
<td>74.18</td>
</tr>
<tr>
<td>25</td>
<td>57</td>
<td>11.68</td>
<td>85.86</td>
</tr>
<tr>
<td>30</td>
<td>30</td>
<td>6.15</td>
<td>92.01</td>
</tr>
<tr>
<td>40</td>
<td>19</td>
<td>3.89</td>
<td>95.90</td>
</tr>
<tr>
<td>50</td>
<td>14</td>
<td>2.87</td>
<td>98.77</td>
</tr>
<tr>
<td>51</td>
<td>6</td>
<td>1.23</td>
<td>100.00</td>
</tr>
<tr>
<td>Total</td>
<td>488</td>
<td>100.00</td>
<td></td>
</tr>
</tbody>
</table>

A value of 5 for `wagecat` represents the category less than 5,000, a value of 10 represents 5,001–10,000, ..., and a value of 51 represents greater than 50,000.

To use `intreg`, we must create two variables, `wage1` and `wage2`, containing the lower and upper endpoints of the wage categories. Here is one way to do it. We first create a dataset containing the nine wage categories, lag the wage categories into `wage1`, and match-merge this dataset with nine observations back into the main one.

```stata
by wagecat: keep if _n==1
(479 observations deleted)
generate wage1 = wagecat[_n-1]
(1 missing value generated)
keep wagecat wage1
save lagwage
file lagwage.dta saved
use http://www.stata-press.com/data/r14/womenwage
(Wages of women)
merge m:1 wagecat using lagwage
```

<table>
<thead>
<tr>
<th>Result</th>
<th># of obs.</th>
</tr>
</thead>
<tbody>
<tr>
<td>not matched</td>
<td>0</td>
</tr>
<tr>
<td>matched</td>
<td>488 (merge==3)</td>
</tr>
</tbody>
</table>
Now we create the upper endpoint and list the new variables:

```
. generate wage2 = wagecat
. replace wage2 = . if wagecat == 51
    (6 real changes made, 6 to missing)
. sort age, stable
. list wage1 wage2 in 1/10
```

```
<table>
<thead>
<tr>
<th>wage1</th>
<th>wage2</th>
</tr>
</thead>
<tbody>
<tr>
<td>. 5</td>
<td>10</td>
</tr>
<tr>
<td>5 10</td>
<td></td>
</tr>
<tr>
<td>5 10</td>
<td></td>
</tr>
<tr>
<td>10 15</td>
<td></td>
</tr>
<tr>
<td>. 5</td>
<td></td>
</tr>
<tr>
<td>. 5</td>
<td></td>
</tr>
<tr>
<td>5 10</td>
<td></td>
</tr>
<tr>
<td>5 10</td>
<td></td>
</tr>
<tr>
<td>5 10</td>
<td></td>
</tr>
</tbody>
</table>
```

We can now run `intreg`:

```
. intreg wage1 wage2 age c.age#c.age nev_mar rural school tenure
```

```
Fitting constant-only model:
Iteration 0:  log likelihood = -967.24956
Iteration 1:  log likelihood = -967.1368
Iteration 2:  log likelihood = -967.1368
Fitting full model:
Iteration 0:  log likelihood = -856.65324
Iteration 1:  log likelihood = -856.33294
Iteration 2:  log likelihood = -856.33293

Interval regression  Number of obs      =      488
                      LR chi2(6)    =    221.61
Log likelihood = -856.33293  Prob > chi2 =      0.000

```

```
| Coef. | Std. Err. | z     | P>|z| | [95% Conf. Interval] |
|-------|-----------|-------|------|----------------------|

Log likelihood = -763.31049

We can directly compare the log likelihoods for the `intreg` and `oprobit` models because both likelihoods are discrete. If we had point data in our `intreg` estimation, the likelihood would be a mixture of discrete and continuous terms, and we could not compare it directly with the `oprobit` likelihood.

Here the `oprobit` log likelihood is significantly larger (that is, less negative), so it fits better than the `intreg` model. The `intreg` model assumes normality, but the distribution of wages is skewed and definitely nonnormal. Normality is more closely approximated if we model the log of wages.
. generate logwage1 = log(wage1)
(14 missing values generated)
. generate logwage2 = log(wage2)
(6 missing values generated)
. intreg logwage1 logwage2 age c.age#c.age nev_mar rural school tenure

Fitting constant-only model:
Iteration 0:  log likelihood = -889.23647
Iteration 1:  log likelihood = -889.06346
Iteration 2:  log likelihood = -889.06346

Fitting full model:
Iteration 0:  log likelihood = -773.81968
Iteration 1:  log likelihood = -773.36566
Iteration 2:  log likelihood = -773.36563

Interval regression Number of obs = 488
LR chi2(6) = 231.40
Log likelihood = -773.36563 Prob > chi2 = 0.0000

The log likelihood of this intreg model is close to the oprobit log likelihood, and the z statistics for both models are similar.

---

Technical note

intreg has two parameterizations for the log-likelihood function: the transformed parameterization ($\beta/\sigma, 1/\sigma$) and the untransformed parameterization ($\beta, \ln(\sigma)$). By default, the log likelihood for intreg is parameterized in the transformed parameter space. This parameterization tends to be more convergent, but it requires that any starting values and constraints have the same parameterization, and it prevents the estimation with multiplicative heteroskedasticity. Therefore, when the het() option is specified, intreg switches to the untransformed log likelihood for the fit of the conditional-variance model. Similarly, specifying from() or constraints() causes the optimization in the untransformed parameter space to allow constraints on (and starting values for) the coefficients on the covariates without reference to $\sigma$.

The estimation results are all stored in the ($\beta, \ln(\sigma)$) metric.
Stored results

intreg stores the following in e():

Scalars

- `e(N)` number of observations
- `e(N_unc)` number of uncensored observations
- `e(N_lc)` number of left-censored observations
- `e(N_rc)` number of right-censored observations
- `e(N_int)` number of interval observations
- `e(k)` number of parameters
- `e(k_aux)` number of auxiliary parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_dv)` number of dependent variables
- `e(ll)` log likelihood
- `e(ll_0)` log likelihood, constant-only model
- `e(ll_c)` log likelihood, comparison model
- `e(N_clust)` number of clusters
- `e(chi2)` $\chi^2$
- `e(p)` $p$-value for model $\chi^2$ test
- `e(sigma)` sigma
- `e(se_sigma)` standard error of sigma
- `e(rank)` rank of `e(V)`
- `e(rank0)` rank of `e(V)` for constant-only model
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise

Macros

- `e(cmd)` `intreg`
- `e(cmdline)` command as typed
- `e(depvar)` names of dependent variables
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(offset)` linear offset variable
- `e(chi2type)` Wald or LR; type of model $\chi^2$ test
- `e(vce)` vcetype specified in vce()
- `e(vcetype)` title used to label Std. Err.
- `e(het)` heteroskedasticity, if `het()` specified
- `e(ml_score)` program used to implement scores
- `e(opt)` type of optimization
- `e(which)` max or min: whether optimizer is to perform maximization or minimization
- `e(ml_method)` type of ml method
- `e(user)` name of likelihood-evaluator program
- `e(technique)` maximization technique
- `e(properties)` `b V`
- `e(predict)` program used to implement predict
- `e(footnote)` program and arguments to display footnote
- `e(marginsok)` predictions allowed by margins
- `e(asbalanced)` factor variables fvset as asbalanced
- `e(asobserved)` factor variables fvset as asobserved

Matrices

- `e(b)` coefficient vector
- `e(Cns)` constraints matrix
- `e(ilog)` iteration log (up to 20 iterations)
- `e(gradient)` gradient vector
- `e(V)` variance–covariance matrix of the estimators
- `e(V_modelbased)` model-based variance

Functions

- `e(sample)` marks estimation sample
Methods and formulas

See Wooldridge (2016, sec. 17.4) for an introduction to censored and truncated regression models.

The likelihood for `intreg` subsumes that of the `tobit` models.

Let $y = X\beta + \epsilon$ be the model. $y$ represents continuous outcomes—either observed or not observed. Our model assumes $\epsilon \sim N(0, \sigma^2 \mathbf{I})$.

For observations $j \in C$, we observe $y_j$, that is, point data. Observations $j \in L$ are left-censored; we know only that the unobserved $y_j$ is less than or equal to $y_{Lj}$, a censoring value that we do know. Similarly, observations $j \in R$ are right-censored; we know only that the unobserved $y_j$ is greater than or equal to $y_{Rj}$. Observations $j \in I$ are intervals; we know only that the unobserved $y_j$ is in the interval $[y_{1j}, y_{2j}]$.

The log likelihood is

$$
\ln L = -\frac{1}{2} \sum_{j \in C} w_j \left\{ \left( \frac{y_j - x_j \beta}{\sigma} \right)^2 + \log 2\pi \sigma^2 \right\} + \sum_{j \in L} w_j \log \Phi\left( \frac{y_{Lj} - x_j \beta}{\sigma} \right) + \sum_{j \in R} w_j \log \left\{ 1 - \Phi\left( \frac{y_{Rj} - x_j \beta}{\sigma} \right) \right\} + \sum_{j \in I} w_j \log \left\{ \Phi\left( \frac{y_{2j} - x_j \beta}{\sigma} \right) - \Phi\left( \frac{y_{1j} - x_j \beta}{\sigma} \right) \right\}
$$

where $\Phi()$ is the standard cumulative normal and $w_j$ is the weight for the $j$th observation. If no weights are specified, $w_j = 1$. If `aweights` are specified, $w_j = 1$, and $\sigma$ is replaced by $\sigma/\sqrt{a_j}$ in the above, where $a_j$ are the `aweights` normalized to sum to $N$.

Maximization is as described in `[R] maximize`; the estimate reported as `sigma` is $\hat{\sigma}$.

See Amemiya (1973) for a generalization of the tobit model to variable, but known, cutoffs.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See `[P] _robust`, particularly Maximum likelihood estimators and Methods and formulas.

`intreg` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] variance estimation.

<td>E(y_j</td>
</tr>
<tr>
<td>ystar(a,b)</td>
<td>E(y_j^<em>, y_j^</em> = max{a, min(y_j, b)})</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

stdf is not allowed with svy postestimation results.

where a and b may be numbers or variables; a missing (a ≥ .) means −∞, and b missing (b ≥ .) means +∞; see [U] 12.2.1 Missing values.

Options for predict

xb, the default, calculates the linear prediction.

stdp calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation’s covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

stdf calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by stdf are always larger than those produced by stdp; see Methods and formulas in [R] regress postestimation.

pr(a,b) calculates Pr(a < x_j b + u_j < b), the probability that y_j | x_j would be observed in the interval (a, b).
a and b may be specified as numbers or variable names; lb and ub are variable names; 
pr(20,30) calculates Pr(20 < x_j b + u_j < 30);
pr(lb,ub) calculates Pr(lb < x_j b + u_j < ub); and
pr(20,ub) calculates Pr(20 < x_j b + u_j < ub). 

a missing (a ≥ .) means −∞; pr(.,30) calculates Pr(−∞ < x_j b + u_j < 30);
pr(lb,30) calculates Pr(−∞ < x_j b + u_j < 30) in observations for which lb ≥ .
and calculates Pr(lb < x_j b + u_j < 30) elsewhere.

b missing (b ≥ .) means +∞; pr(20,.) calculates Pr(+∞ > x_j b + u_j > 20);
pr(20,ub) calculates Pr(+∞ > x_j b + u_j > 20) in observations for which ub ≥ .
and calculates Pr(20 < x_j b + u_j < ub) elsewhere.

e(a,b) calculates E(x_j b + u_j | a < x_j b + u_j < b), the expected value of y_j|x_j conditional on 
y_j|x_j being in the interval (a,b), meaning that y_j|x_j is truncated.
a and b are specified as they are for pr().

ystar(a,b) calculates E(y_j^*), where y_j^* = a if x_j b + u_j ≤ a, y_j^* = b if x_j b + u_j ≥ b, and 
y_j^* = x_j b + u_j otherwise, meaning that y_j^* is censored. a and b are specified as they are for pr().

nooffset is relevant only if you specified offset(varname). It modifies the calculations made by 
predict so that they ignore the offset variable; the linear prediction is treated as x_j b rather than 
as x_j b + offset_j.

scores calculates equation-level score variables.
The first new variable will contain ∂ln L/∂(x_j β).
The second new variable will contain ∂ln L/∂lnσ.
margins

Description for margins

margins estimates margins of response for linear predictions, probabilities, and expected values.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [ marginlist ] [, options ]
margins [ marginlist ] , predict(statistic ...) [ predict(statistic ...) ... ] [ options ]

<table>
<thead>
<tr>

<td>not allowed with margins</td>
</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see [R] margins.
Remarks and examples

Example 1

We continue with example 1 of [R] intreg.

. use http://www.stata-press.com/data/r14/intregxmpl
. intreg wage1 wage2 age c.age#c.age nev_mar rural school tenure
  (output omitted)

By default, the predict command produces the linear prediction, which in this case is the expected wage for each individual.

. predict w1
  (option xb assumed; fitted values)

We can use the e(a,b) option to compute the expected wage, conditional on it being larger than $5,000:

. predict w2, e(5,.)

The probability of earning more than $5,000 might vary with age. We can use margins to compute the marginal means for those probabilities for different ages.

. margins, predict(pr(5,.)) at(age=(20(5)50))

Predictive margins Number of obs = 488
Model VCE : OIM
Expression : Pr(y>5), predict(pr(5,.))
1._at : age = 20
2._at : age = 25
3._at : age = 30
4._at : age = 35
5._at : age = 40
6._at : age = 45
7._at : age = 50

<table>
<thead>
<tr>
<th>_at</th>
<th>Delta-method</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Margin</td>
</tr>
<tr>
<td>1</td>
<td>.8912598</td>
</tr>
<tr>
<td>2</td>
<td>.9104568</td>
</tr>
<tr>
<td>3</td>
<td>.9160005</td>
</tr>
<tr>
<td>4</td>
<td>.9096667</td>
</tr>
<tr>
<td>5</td>
<td>.8894289</td>
</tr>
<tr>
<td>6</td>
<td>.8491103</td>
</tr>
<tr>
<td>7</td>
<td>.7781644</td>
</tr>
</tbody>
</table>
We can visualize these results by using `marginsplot`:

```
. quietly margins, predict(pr(5,.)) at(age=(20(5)50))
. marginsplot
```

Variables that uniquely identify margins: age

The probability increases until age 30, and it decreases after that age.

[R] `intreg` — Interval regression
[U] 20 Estimation and postestimation commands
ivpoisson estimates the parameters of a Poisson regression model in which some of the covariates are endogenous. The model is also known as an exponential conditional mean model in which some of the covariates are endogenous. The model may be specified using either additive or multiplicative error terms. The model is frequently used to model count outcomes and is also used to model nonnegative outcome variables.

Quick start

Two-step GMM estimation of the Poisson regression of \( y_1 \) on \( x \) and endogenous regressor \( y_2 \) that is instrumented using \( z \)

\[
iivpoisson \text{ gmm } y_1 \ x \ (y_2 = z)
\]

As above, but specify multiplicative errors rather than additive

\[
iivpoisson \text{ gmm } y_1 \ x \ (y_2 = z), \text{ multiplicative}
\]

Use iterative GMM estimation

\[
iivpoisson \text{ gmm } y_1 \ x \ (y_2 = z), \text{ igmm}
\]

Specify a weight matrix that allows for correlation within clusters identified by \( cvar \)

\[
iivpoisson \text{ gmm } y_1 \ x \ (y_2 = z), \text{ wmatrix(cluster cvar)}
\]

Use the control-function estimator

\[
iivpoisson \text{ cfunction } y_1 \ x \ (y_2 = z)
\]
Syntax

**Generalized method of moments estimator**

```
ivpoisson gmm depvar [varlist1] [ (varlist2 = varlistIV) ] [ if ] [ in ] [ weight ]

[, reg_err_opt options ]
```

**Control-function estimator**

```
ivpoisson cfunction depvar [varlist1] (varlist2 = varlistIV) [ if ] [ in ] [ weight ]

[, options ]
```

---

## Description

### Model

- **noconstant**
  - suppress constant term
- **exposure(varname_e)**
  - include \( \ln(varname_e) \) in model with coefficient constrained to 1
- **offset(varname_o)**
  - include \( varname_o \) in model with coefficient constrained to 1
- **twostep**
  - use two-step GMM estimator; the default for `ivpoisson gmm`
- **onestep**
  - use one-step GMM estimator; the default for `ivpoisson cfunction`
- **igmm**
  - use iterative GMM estimator

### Weight matrix

- **wmatrix(wmtype)**
  - specify weight matrix; \( wmtype \) may be \( \text{robust, cluster clustvar, or unadjusted} \)
- **center**
  - center moments in weight-matrix computation
- **winitial(iwtype[, independent])**
  - specify initial weight matrix; \( iwtype \) may be \( \text{unadjusted, identity, or the name of a Stata matrix} \)
  - \( \text{(independent may not be specified with ivpoisson gmm)} \)

### SE/Robust

- **vce(vcetype)**
  - \( vcetype \) may be \( \text{robust, cluster clustvar, bootstrap, jackknife, or unadjusted} \)

### Reporting

- **level(#)**
  - set confidence level; default is \( \text{level(95)} \)
- **irr**
  - report incidence-rate ratios
- **display_options**
  - control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

### Optimization

- **from(initial_values)**
  - specify initial values for parameters
- **† igmmiterate(#)**
  - specify maximum number of iterations for iterated GMM estimator
- **‡ igmmeps(#)**
  - specify \( # \) for iterated GMM parameter convergence criterion; default is \( \text{igmmeps(1e-6)} \)
- **‡ igmmweps(#)**
  - specify \( # \) for iterated GMM weight-matrix convergence criterion; default is \( \text{igmmweps(1e-6)} \)
- **optimization_options**
  - control the optimization process; seldom used

---

* You can specify at most one of these options.

† These options may be specified only when `igmm` is specified.

varlist1 and varlist1iv may contain factor variables; see [U] 11.4.3 Factor variables.

deprevar, varlist1, varlist2, and varlist1iv may contain time-series operators; see [U] 11.4.4 Time-series varlists.

bootstrap, by, jackknife, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

aweights are not allowed with the jackknife prefix; see [R] jackknife.

aweights, feweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
Options

noconstant, exposure(varname_e), offset(varname_o); see [R] estimation options.

additive, the default, specifies that the regression errors be added to the conditional mean term and have mean 0.

multiplicative specifies that the regression errors be multiplied by the conditional mean term and have mean 1.

twostep, onestep, and igmm specify which estimator is to be used.

twostep requests the two-step GMM estimator. gmm obtains parameter estimates based on the initial weight matrix, computes a new weight matrix based on those estimates, and then reestimates the parameters based on that weight matrix. twostep is the default for ivpoisson gmm.

onestep requests the one-step GMM estimator. The parameters are estimated based on an initial weight matrix, and no updating of the weight matrix is performed except when calculating the appropriate variance–covariance (VCE) matrix. onestep is the default for ivpoisson cfunction.

igmm requests the iterative GMM estimator. gmm obtains parameter estimates based on the initial weight matrix, computes a new weight matrix based on those estimates, reestimates the parameters based on that weight matrix, computes a new weight matrix, and so on, to convergence. Convergence is declared when the relative change in the parameter vector is less than igmmeeps(), the relative change in the weight matrix is less than igmmweps(), or igmmiterate() iterations have been completed. Hall (2005, sec. 2.4 and 3.6) mentions that there may be gains to finite-sample efficiency from using the iterative estimator.

Weight matrix

wmatrix(wmtype) specifies the type of weight matrix to be used in conjunction with the two-step and iterated GMM estimators.

Specifying wmatrix(robust) requests a weight matrix that is appropriate when the errors are independent but not necessarily identically distributed. wmatrix(robust) is the default.

Specifying wmatrix(cluster clustvar) requests a weight matrix that accounts for arbitrary correlation among observations within clusters identified by clustvar.

Specifying wmatrix(unadjusted) requests a weight matrix that is suitable when the errors are homoskedastic.

wmatrix() cannot be specified if onestep is also specified.

center requests that the sample moments be centered (demeaned) when computing GMM weight matrices. By default, centering is not done.

winitial(wmtype[, independent]) specifies the weight matrix to use to obtain the first-step parameter estimates.

Specifying winitial(unadjusted) requests a weighting matrix that assumes the error functions are independent and identically distributed. This matrix is of the form $(Z'Z)^{-1}$, where $Z$ represents all the exogenous and instrumental variables.

winitial(identity) requests that the identity matrix be used.

winitial(matname) requests that Stata matrix matname be used.
Including the `independent` suboption creates a weight matrix that assumes error functions are independent. Elements of the weight matrix corresponding to covariances between any two error functions are set equal to zero. This suboption only applies to `ivpoisson cfunction`.

`winitial(unadjusted)` is the default for `ivpoisson gmm`.

`winitial(unadjusted, independent)` is the default for `ivpoisson cfunction`.

**SE/Robust**

`vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster `clustvar`), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] `vce_option`.

`vce(unadjusted)` specifies that an unadjusted (nonrobust) VCE matrix be used; this, along with the `twostep` option, results in the “optimal two-step GMM” estimates often discussed in textbooks. `vce(unadjusted)` may not be set in `ivpoisson cfunction`.

The default `vcetype` is based on the `wmtype` specified in the `wmatrix()` option. If `wmatrix()` is specified but `vce()` is not, then `vcetype` is set equal to `wmtype`. To override this behavior in `ivpoisson gmm` and obtain an unadjusted (nonrobust) VCE matrix, specify `vce(unadjusted)`. The default `vcetype` for `ivpoisson cfunction` is `robust`.

Specifying `vce(bootstrap)` or `vce(jackknife)` results in standard errors based on the bootstrap or jackknife, respectively. See [R] `vce_option`, [R] `bootstrap`, and [R] `jackknife` for more information on these VCEs.

The syntax for `vcetypes` is identical to those for `wmatrix()`.

**Reporting**

`level(#)`; see [R] `estimation options`.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is, $e^{\beta_i}$ rather than $\beta_i$. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results. `irr` is not allowed with additive.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%)`, `pformat(%)`, `sformat(%)`, and `nolstretch`; see [R] `estimation options`.

**Optimization**

`from(initial_values)` specifies the initial values to begin the estimation. You can specify a $1 \times k$ matrix, where $k$ is the number of parameters in the model, or you can specify a parameter name, its initial value, another parameter name, its initial value, and so on. For example, to initialize the coefficient for `male` to 1.23 and the constant `_cons` to 4.57, you would type

```
ivpoisson ..., from(male 1.23 _cons 4.57) ...
```

Initial values declared using this option override any that are declared within substitutable expressions. If you specify a parameter that does not appear in your model, `ivpoisson` exits with error code 480. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model. `ivpoisson` ignores the row and column names of the matrix.

`igmmiterate(#)`, `igmmeps(#)`, and `igmmweps(#)` control the iterative process for the iterative GMM estimator for `ivpoisson`. These options can be specified only if you also specify `igmm`.
ivpoisson — Poisson model with continuous endogenous covariates

igmmiterate(#) specifies the maximum number of iterations to perform with the iterative GMM estimator. The default is the number set using set maxiter (set [R] maximize), which is 16,000 by default.

igmmeps(#) specifies the convergence criterion used for successive parameter estimates when the iterative GMM estimator is used. The default is igmmeps(1e-6). Convergence is declared when the relative difference between successive parameter estimates is less than igmmeps() and the relative difference between successive estimates of the weight matrix is less than igmmweps().

igmmweps(#) specifies the convergence criterion used for successive estimates of the weight matrix when the iterative GMM estimator is used. The default is igmmweps(1e-6). Convergence is declared when the relative difference between successive parameter estimates is less than igmmeps() and the relative difference between successive estimates of the weight matrix is less than igmmweps().

optimization_options: technique(), conv_maxiter(), conv_ptol(), conv_vtol(), conv_nrtol(), and tracelevel(). technique() specifies the optimization technique to use; gn (the default), nr, dfp, and bfgs are allowed. conv_maxiter() specifies the maximum number of iterations; conv_ptol(), conv_vtol(), and conv_nrtol() specify the convergence criteria for the parameters, gradient, and scaled Hessian, respectively. tracelevel() allows you to obtain additional details during the iterative process. See [M-5] optimize().

Remarks and examples

ivpoisson estimates the parameters of a Poisson regression model in which some of the covariates are endogenous. A regressor is endogenous if it is related to the unobserved error term. The model is also known as an exponential conditional mean model in which some of the covariates are endogenous. The model may be specified using either additive or multiplicative error terms.

The model is frequently used to model count outcomes and is also used to model nonnegative outcome variables. Poisson regression is a special exponential conditional mean model. See [R] poisson for more information on Poisson regression.

The exponential conditional mean model has an error form representation in which the dependent variable \( y \) is a function of the exogenous covariates \( x \), endogenous covariates \( y_2 \), and an error \( \epsilon \). The covariates \( x \) are independent of \( \epsilon \), while \( y_2 \) are not.

ivpoisson allows \( \epsilon \) to enter either additively,

\[ y_i = \exp(x'_i \beta_1 + y'_2,i \beta_2) + \epsilon_i \]

or multiplicatively,

\[ y_i = \exp(x'_i \beta_1 + y'_2,i \beta_2) \epsilon_i \]

Mullahy (1997), Cameron and Trivedi (2013), Windmeijer and Santos Silva (1997), and Wooldridge (2010) discuss the generalized method of moments (GMM) estimators implemented in ivpoisson. GMM is frequently used in modern econometrics. Many econometric and statistical models can be expressed as conditions on the population moments. The parameter estimates produced by GMM estimators make the sample-moment conditions as true as possible given the data. See [R] gmm for further information on GMM estimation and how Stata performs it.

The rest of the discussion is presented under the following headings:

- GMM estimator for additive model
- GMM estimator for multiplicative model
- CF estimator for multiplicative model
GMM estimator for additive model

The GMM estimator uses additional variables, known as instruments and denoted by \( z_i \), to specify moment conditions that hold in the population. The GMM parameter estimates make the sample versions of these population-moment conditions as close to true as possible. The instrumental variables are assumed to be correlated with the endogenous covariates \( y_{2,i} \) but independent of the errors \( \epsilon_i \).

Under additive errors, the dependent variable \( y_i \) is determined by exogenous covariates \( x_i \), endogenous covariates \( y_{2,i} \), and zero-mean error \( \epsilon_i \) as

\[
y_i = \exp(x_i' \beta_1 + y_{2,i}' \beta_2) + \epsilon_i
\]

This leads to the following error function

\[
u(y_i, x_i, y_{2,i}, \beta_1, \beta_2) = y_i - \exp(x_i' \beta_1 + y_{2,i}' \beta_2)\]

The population-moment conditions for GMM estimation are \( E \{ \tilde{z}_i u(y_i, x_i, y_{2,i}, \beta_1, \beta_2) \} = 0 \), where the vector \( \tilde{z}_i \) is partitioned as \( (x_i', z_i') \). The sample-moment conditions are formed by replacing the expectation with the corresponding sample mean. The GMM estimator solves a minimization problem to make the sample-moment conditions as close to zero as possible. Details on how estimation is performed are given in Methods and formulas.

Now we will demonstrate how \texttt{ivpoisson gmm} works in the additive error setting with an example.

\begin{itemize}
    \item \textbf{Example 1: ivpoisson gmm with additive errors}
\end{itemize}

This example uses simulated data based on the following story. A news website randomly samples 500 young adults in a major city. The website wants to model the number of times the sampled individuals visit its website (visits) based on their overall time spent on the Internet (time) and the number of times they receive an ad for the website through email or viewing another website (ad). The website also suspects the gender of the individual may matter, so an exogenous dummy variable, female, is included in the model.

We suspect time spent on the Internet is correlated with unobserved factors that additively affect the number of times an individual visits the website. So we treat time as an endogenous regressor. Two instruments are used for this variable. The time spent on the phone (phone) is one instrument. The other instrument is the time spent interacting with friends and family that live out of town (frfam).

We model the number of visits the website receives using an exponential conditional mean model with additive errors and use \texttt{ivpoisson gmm} to estimate the parameters of the regression in the output below. To allow for heteroskedasticity of the errors, we use robust standard errors, which is the default; see \textit{Obtaining standard errors} in \texttt{[R] gmm} for a discussion of why robust standard errors is the default.

```stata

Instrumented: time
Instruments: ad female phone frfam

We find significant coefficients for all covariates but female. At fixed values of the other covariates, increased time spent on the Internet will raise the expected number of website visits. Receiving additional advertisements will also cause an increase in the expected number of website visits.

**GMM estimator for multiplicative model**

Under multiplicative errors, the dependent variable $y_i$ is determined by exogenous covariates $x_i$, endogenous covariates $y_{2,i}$, and unit-mean errors $\epsilon_i$ as

$$y_i = \exp(x_i'\beta_1 + y_{2,i}'\beta_2)\epsilon_i$$

This setting yields a different error function than the additive error case. This ratio formulation is

$$u(y_i, x_i, y_{2,i}, \beta_1, \beta_2) = y_i / \exp(x_i'\beta_1 + y_{2,i}'\beta_2) - 1$$

Given the instrumental variables $z$, the population-moment conditions for GMM estimation are

$$E \{\tilde{z}_i u(y_i, x_i, y_{2,i}, \beta_1, \beta_2)\} = 0.$$  

The vector $\tilde{z}_i$ is partitioned as $(x_i', z_i')$. As above, the sample-moment conditions are the sample analogs of the population-moment conditions, and the GMM estimator solves a minimization problem to make the sample-moment conditions as close to zero as possible. Details on how estimation is performed are given in *Methods and formulas*.

**Example 2: ivpoisson gmm with multiplicative errors**

In this example, we observe a simulated random sample of 5,000 households. We model the number of trips taken by members of the household in the 24-hour period immediately prior to the interview time by using an exponential conditional mean model with multiplicative errors. Exogenous covariates include the distance to the central business district from the household (cbd), the distance from the household to a public transit node (ptn), whether there is a full-time worker in the household (worker), and whether the examined period is on a weekend (weekend). We suspect that the endogenous regressor, the transportation cost of the household in the prior week (tcost), is correlated with unobserved factors that affect the number of trips taken. This transportation cost includes gasoline and bus, train tickets, etc.

The ratio of the cost of a public transit day pass in the sampled area to the national average cost of such a pass (pt) is also observed. This is used as an instrument for transportation cost.
In the output below, we estimate the parameters of the regression with `ivpoisson gmm`. To allow for heteroskedasticity of the errors, we use robust standard errors, which is the default.

```
use http://www.stata-press.com/data/r14/trip
(Household trips)
.ivpoisson gmm trips cbd ptn worker weekend (tcost = pt), multiplicative
```

**Step 1**

Instrumented: tcost

Instruments: cbd ptn worker weekend pt

We find that all coefficients are significant. At fixed values of the other covariates, we see that additional mileage from the central business district and public transit nodes reduces the expected number of trips taken. Individuals who live farther away from the central business district may still be out of the house the same amount of time, but they will take fewer trips because the transit time has increased. The situation is similar for those who live farther from public transit.

To interpret the other parameters, we will look at the partial effects of their respective independent variables. The partial effects of a change in an independent variable on the modeled conditional expectation function vary over the data because the model is nonlinear. However, under the multiplicative error model, the ratio of the new value to the old value after a discrete change in an independent variable is constant over the data.

Let \( \mathbf{w} = (\mathbf{x}', \mathbf{y}_2')' \). If we add 1 to the \( j \)th independent variable in \( \mathbf{w} \), the functional form of the model implies that

\[
\frac{E(y|\mathbf{w}, w_j + 1, \epsilon)}{E(y|\mathbf{w}, w_j, \epsilon)} = \frac{E(y|w_1, \ldots, w_j + 1, \ldots, w_k, \epsilon)}{E(y|w_1, \ldots, w_j, \ldots, w_k, \epsilon)} = e^{\beta_j}
\]

When \( y \) is a count variable, this normalized effect is called the incidence-rate ratio (IRR) for a one-unit change in \( w_j \).

More generally, the IRR for a \( \Delta w_j \) change in \( w_j \) is \( e^{\beta_j \Delta w_j} \) under a multiplicative-error exponential conditional mean model. We can calculate incidence-rate ratios for different changes in the covariates by using `lincom`; see [R] `lincom`. 
Here we replay the `ivpoisson` results by typing the command name and we specify the `irr` option to get the incidence-rate ratios. Each significance test for a coefficient equaling zero becomes a test for the incidence-rate ratio equaling one.

```

Holding other covariates and the error constant, the expected number of trips made from houses with a full-time worker is nearly twice that of those houses without a full-time worker. Similarly, the expected number of trips made during a weekend day is close to 35% higher than the expected number of trips made on other days. For each additional dollar of weekly transportation cost, the expected number of household trips is increased by approximately 3.6%.

### CF estimator for multiplicative model

Control-function (CF) estimators can be used to account for endogenous covariates. As Wooldridge (2010, sec. 18.5) describes, CF estimators assume a certain structural relationship between the endogenous covariates and the exogenous covariates and use functions of first-stage parameter estimates to control for the endogeneity in the second stage.
Wooldridge (2010, sec. 18.5) notes that the VCE of the second-stage estimator must be adjusted to account for estimates from the first stage. `ivpoisson cfunction` solves this problem by stacking the moment conditions that define each stage and applying a single GMM estimator. See Newey (1984) and Wooldridge (2010, sec. 14.2) for a description of this technique. No adjustment to the VCE is necessary because there is only one stage.

The CF estimator augments the original multiplicative model with an estimated term that controls for the endogeneity of \( y_{2,i} \). When \( y_{2,i} \) is exogenous, the coefficient on this control term is zero. Let \( z \) be instrumental variables, and the vector \( \tilde{z}_i \) be \((x_i', z_i')\).

The augmented model is

\[
y_i = \exp(x_i'\beta_1 + y_{2,i}'\beta_2 + v_i'\rho + c_i)
\]

where

\[
y_{2,i} = B\tilde{z}_i' + v_i
\]

The term \( v_i'\rho \) controls for the endogeneity of \( y_{2,i} \), and we normalize \( E\{\exp(c_i)\} = 1 \). The coefficient vector \( \rho \) measures the strength of the endogeneity of \( y_{2,i} \); \( y_{2,i} \) is exogenous when \( \rho = 0 \).

`ivpoisson cfunction` estimates \( \beta_1 \) and \( \beta_2 \) and the auxiliary parameters \( \rho \) and \( B \) by GMM; see Methods and formulas for details.

Example 3: Control-function estimator

We return to the previous example, where we estimated the parameters of an exponential conditional mean model for the number of trips taken by a household in a 24-hour period. We will estimate the parameters of the regression with the CF estimator method and compare our results with those obtained with the GMM estimator in example 2.

In the output below, we estimate the parameters of the regression with the `ivpoisson cfunction` command.

The output table presents results for the estimated coefficients in each of three equations. First, in the trips equation, we see the results for the estimated coefficients in the equation for the dependent variable trips. Second, in the tcost equation, we see the estimated coefficients in the regression of tcost on the instrumental and exogenous variables. Third, the /c_tcost ancillary parameter corresponds to the estimate of ρ, the coefficient on the residual variable included to control for the endogeneity of tcost.

We find that all coefficients are significant in the exponential conditional mean equation, trips. The coefficient estimates in the trips equation are similar to the estimates obtained by the GMM estimator in example 2. That the estimated coefficient on the tcost control variable is significantly different from zero suggests that tcost is endogenous.
Stored results

ivpoisson stores the following in e():

Scalars
- e(N): number of observations
- e(k): number of parameters
- e(k_eq): number of equations
- e(k_aux): number of auxiliary parameters
- e(k_dv): number of dependent variables
- e(Q): criterion function
- e(J): Hansen $J \chi^2$ statistic
- e(J_df): $J$ statistic degrees of freedom
- e(N_clust): number of clusters
- e(rank): rank of e(V)
- e(ic): number of iterations used by iterative GMM estimator
- e(converged): 1 if converged, 0 otherwise

Methods and formulas

The estimators in ivpoisson are GMM estimators that can be expressed in terms of error functions and the instruments that are used to form the moment conditions. When offsets $o_j^\beta$ are used in the outcome variable equation, the following formulas apply with $x'_j \beta_1$ changed to $x'_j \beta_1 + o_j^\beta$.

The error functions for the GMM estimators are given in the text.

Here we provide some details about the form of the error function used by the CF estimator.

Recall that the multiplicative model is

$$y_i = \exp(x'_i \beta_1 + y'_2 \beta_2) \epsilon_i$$

We parameterize the endogenous variables in the form

$$y_{2,i} = B \tilde{z}_i' + v_i$$

This allows us to decompose $\epsilon_i$ as

$$\epsilon_i = \exp(v'_i \rho + c_i)$$

Given this setup, we obtain the following conditional mean:

$$E(y|x_i, z_i, y_{2,i}, v_i) = \exp(x'_i \beta_1 + y'_2 \beta_2 + v'_i \rho)$$

We estimate $v_i$ as the residuals of the linear regression of $y_{2,i}$ on $\tilde{z}_i$. The estimates of $v_i$ are used as additional covariates in the exponential conditional mean model for $y$ to estimate $\beta_1$, $\beta_2$, and $\rho$. In essence, the estimates of $v_i$ control for the endogeneity.

The error functions for the endogenous covariates are defined as

$$u_{en,i}(y_{2,i}, \tilde{z}_i, B) = y_{2,i} - B \tilde{z}_i'$$

Now we define the error function for the dependent variable as

$$u_y(y_i, x_i, y_{2,i}, u_{en,i}, \beta_1, \beta_2, \rho) = y_i/\exp(x'_i \beta_1 + y'_2 \beta_2 + u'_{en,i} \rho) - 1$$

$u_{en,i}$ will be vector valued if we have multiple endogenous covariates $y_{2,i}$. Call the dimension of $y_{2,i} g$. $u_{en,i}$ and $u_y$ define $g + 1$ separate error functions. We will use variables $\tilde{z}_i$ to instrument each error function in $u_{en,i}$. So for error function $j = 1, \ldots, g$, we have the error function $u_{en,i,j}$ and the population-moment conditions $E(\tilde{z}_i u_{en,i,j}) = 0$.

We calculate $\tilde{v}_{oi}$ previous to estimation as the residuals of the linear regression of $y_{2,i}$ on $\tilde{z}_i$. We use variables $x_i$, $y_{2,i}$, and $\tilde{v}_{oi}$ to instrument the error function $u_y$. This leads to the population-moment conditions $E\{(x'_i, y'_{2,i}, \tilde{v}_{oi}) u_y, i\} = 0$

Details of GMM estimation can be found in Methods and formulas of [R] gmm. Determination of the weight matrix $W_N$ is discussed there.

Under the GMM estimation, the GMM estimators $\hat{\beta}_1$ and $\hat{\beta}_2$ are the values of $\beta_1$ and $\beta_2$ that minimize

$$Q(\hat{\beta}_1, \hat{\beta}_2) = \left\{\frac{1}{N} \sum_i \tilde{z}_i u_i (y_i, x_i, y_{2,i}, \beta_1, \beta_2)\right\}' W_N \left\{\frac{1}{N} \sum_i \tilde{z}_i u_i (y_i, x_i, y_{2,i}, \beta_1, \beta_2)\right\}$$ (1)
for $q \times q$ weight matrix $W_N$, where $q$ is the dimension of $\tilde{z}_i$. The error functions $u_i$ were defined in the text.

In the CF method, we have multiple error functions as defined above. We can stack the moment conditions and write them more compactly as $Z'_i u_i(B, \beta_1, \beta_2, \rho)$, where

$$Z_i = \begin{bmatrix}
x'_i & 0 & 0 & \ldots & 0 \\
0 & y'_{2,i} & 0 & \ldots & 0 \\
0 & 0 & \tilde{z}_i & \ldots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \ldots & \tilde{z}_i
\end{bmatrix}$$

and

$$u_i(B, \beta_1, \beta_2, \rho) = \begin{bmatrix}
u_y(y_i, x_i, y_{2,i}, u_{en,i}, \beta_1, \beta_2, \rho) \\
u_{en}(y_{2,i}, \tilde{z}_i, B)
\end{bmatrix}$$

The matrix $Z_i$ has $g + 1$ rows and $k + gz$ columns, where $k$ is the number of covariates for $y_i$ and $z$ is the number of exogenous covariates in $\tilde{z}_i$.

The GMM estimators $\hat{B}$, $\hat{\beta}_1$, $\hat{\beta}_2$, and $\hat{\rho}$ are the values of $B$, $\beta_1$, $\beta_2$, and $\rho$ that minimize

$$Q(B, \beta_1, \beta_2, \rho) = \left\{ N^{-1} \sum_{i=1}^{N} Z'_i u_i(B, \beta_1, \beta_2, \rho) \right\}' W_N \left\{ N^{-1} \sum_{i=1}^{N} Z'_i u_i(B, \beta_1, \beta_2, \rho) \right\}$$

for $(k + gz) \times (k + gz)$ weight matrix $W_N$.

By default, ivpoisson minimizes (1) and (2) using the Gauss–Newton method. See Hayashi (2000, 498) for a derivation. This technique is typically faster than quasi-Newton methods and does not require second-order derivatives.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

n, the default, calculates the predicted number of events via the exponential-form estimate. This is \( \exp(x'_j\beta_1 + y'_{2,j}\beta_2) \) if neither offset() nor exposure() was specified, \( \exp(x'_j\beta_1 + y'_{2,j}\beta_2 + \text{offset}_j) \) if offset() was specified, or \( \exp(x'_j\beta_1 + y'_{2,j}\beta_2) \times \text{exposure}_j \) if exposure() was specified.

After generalized method of moments estimation, the exponential-form estimate is not a consistent estimate of the conditional mean of \( y_j \), because it is not corrected for \( E(\epsilon_j|y_{2,j}) \). More details are found in Methods and formulas.

After control-function estimation, we correct the exponential-form estimate for \( E(\epsilon_j|y_{2,j}) \) by using the estimated residuals of \( y_{2,j} \) and the \( c-* \) auxiliary parameters. This supplements the direct effect of \( y_{2,j} \) and \( x_j \) through \( \beta_1 \) and \( \beta_2 \) with the indirect effects of \( y_{2,j}, x_j \), and the instruments \( z_j \) through the endogenous error \( \epsilon_j \). Thus the exponential-form estimate consistently estimates the conditional mean of \( y_j \).

xbtotal calculates the linear prediction, which is \( x'_j\beta_1 + y'_{2,j}\beta_2 \) if neither offset() nor exposure() was specified, \( x'_j\beta_1 + y'_{2,j}\beta_2 + \text{offset}_j \) if offset() was specified, or \( x'_j\beta_1 + y'_{2,j}\beta_2 + \ln(\text{exposure}_j) \) if exposure() was specified.

After control-function estimation, the estimate of the linear form \( x'_j\beta_1 \) includes the estimated residuals of the endogenous regressors with coefficients from the \( c-* \) auxiliary parameters.
The linear prediction, which is $x_j' \beta_1 + y_{2,j}' \beta_2$ if neither offset() nor exposure() was specified, $x_j' \beta_1 + y_{2,j}' \beta_2 + \text{offset}_j$ if offset() was specified, or $x_j' \beta_1 + y_{2,j}' \beta_2 + \ln(\text{exposure}_j)$ if exposure() was specified. See nooffset below.

residuals calculates the residuals. Under additive errors, these are calculated as $y_j - \exp(x_j' \beta_1 + y_{2,j}' \beta_2)$. Under multiplicative errors, they are calculated as $y_j / \exp(x_j' \beta_1 + y_{2,j}' \beta_2) - 1$.

When offset() or exposure() is specified, $x_j' \beta_1$ is not used directly in the residuals. $x_j' \beta_1 + \text{offset}_j$ is used if offset() was specified. $x_j' \beta_1 + \ln(\text{exposure}_j)$ is used if exposure() was specified. See noffset below.

After control-function estimation, the estimate of the linear form $x_j' \beta_1$ includes the estimated residuals of the endogenous regressors with coefficients from the $c_*$ auxiliary parameters.

noffset is relevant only if you specified offset() or exposure() when you fit the model. It modifies the calculations made by predict so that they ignore the offset or exposure variable. noffset removes the offset from calculations involving both the treat() equation and the dependent count variable.

**margins**

**Description for margins**

margins estimates margins of response for numbers of events and linear predictions.

**Menu for margins**

For the full syntax, see [R] margins.
estat

Description for estat

estat overid reports Hansen’s J statistic, which is used to determine the validity of the overidentifying restrictions in a GMM model. ivpoisson gmm uses GMM estimation to obtain parameter estimates. Under additive and multiplicative errors, Hansen’s J statistic can be accurately reported when more instruments than endogenous regressors are specified. It is not appropriate to report the J statistic after ivpoisson cfunction, because a just-identified model is fit.

If the model is correctly specified in the sense that \( E \{ \tilde{z}_i u(y_i, x_i, y_{2,i}, \beta) \} = 0 \), then the sample analog to that condition should hold at the estimated value of \( \beta_1 \) and \( \beta_2 \). The \( \tilde{z}_i \) variables are the exogenous regressors \( x_i \) and instrumental variables \( z_i \) used in ivpoisson gmm. The \( y_{2,i} \) are the endogenous regressors. The \( u \) function is the error function, which will have a different form for multiplicative and additive errors in the regression.

Hansen’s J statistic is valid only if the weight matrix is optimal, meaning that it equals the inverse of the covariance matrix of the moment conditions. Therefore, estat overid only reports Hansen’s J statistic after two-step or iterated estimation or if you specified winitial(matname) when calling ivpoisson gmm. In the latter case, it is your responsibility to determine the validity of the J statistic.

Menu for estat

Statistics > Postestimation

Syntax for estat

estat overid

Remarks and examples

estat overid reports Hansen’s J statistic, which is used to determine the validity of the overidentifying restrictions in a GMM model. It is not appropriate to use it after ivpoisson cfunction, because a just-identified model is fit.

Recall that the GMM criterion function is

\[
Q(\beta) = \left\{ \frac{1}{N} \sum_i \tilde{z}_i u(y_i, x_i, y_{2,i}, \beta_1, \beta_2) \right\}' W_N \left\{ \frac{1}{N} \sum_i \tilde{z}_i u(y_i, x_i, y_{2,i}, \beta_1, \beta_2) \right\}
\]

(A1)

Our \( u \) function within this formula will change depending on whether we use additive or multiplicative errors. The \( \tilde{z} \) vector contains the exogenous regressors and instrumental variables used. ivpoisson gmm estimates regression coefficients to minimize \( Q \).

Let \( l \) be the dimension of \( \tilde{z} \) and \( k \) the number of regressors. If \( W_N \) is an optimal weight matrix, under the null hypothesis \( H_0: E \{ \tilde{z}_i u(y_i, x_i, y_{2,i}, \beta_1, \beta_2) \} = 0 \), the test statistic \( J = N \times Q \sim \chi^2(l - k) \). A large test statistic casts doubt on the null hypothesis.

Because the weight matrix \( W_N \) must be optimal, estat overid works only after the two-step and iterated estimation or if you supplied your own initial weight matrix by using the winitial(matname) option of ivpoisson gmm and used the one-step estimator.
Often the overidentifying restrictions test is interpreted as a test of the validity of the instruments \( z \). However, other forms of model misspecification can sometimes lead to a significant test statistic. See Hall (2005, sec. 5.1) for a discussion of the overidentifying restrictions test and its behavior in correctly specified and misspecified models.

Note that `ivpoisson gmm` defaults to the two-step estimator when other options are not specified to override the default. Thus it is appropriate to perform the \( J \) test after the regression of example 1 in [R] `ivpoisson`.

### Example 1: Specification test

Recall example 1 of [R] `ivpoisson`. We estimated the parameters of an exponential conditional mean model for the number of visits to a website. Additive errors were used. Exogenous regressors included the gender of an individual and the number of ads received from the website.

An endogenous regressor, time spent on the Internet, was also included in the model. Two instruments were used. One of the instruments measured the time spent interacting with friends and out-of-town family. The other measured the time spent on the phone.

We will reestimate the parameters of the regression here and then test the specification.

```
. use http://www.stata-press.com/data/r14/website
   (Visits to website)
. ivpoisson gmm visits ad female (time = phone frfam)
   (output omitted)
. estat overid
   Test of overidentifying restriction:
   Hansen’s J ch2(1) = .129055 (p = 0.7194)
```

We have two instruments for one endogenous variable, so the \( J \) statistic has one degree of freedom. The \( J \) statistic is not significant. We fail to reject the null hypothesis that the model is correctly specified.

### Stored results

`estat overid` stores the following in `r()`:

- Scalars
  - `r(J)` Hansen’s \( J \) statistic
  - `r(J df)` \( J \) statistic degrees of freedom
  - `r(J p)` \( J \) statistic \( p \)-value

### Methods and formulas

The vector \( x_i \) contains the exogenous regressors, and \( z_i \) the instruments. The vector \( \tilde{z}_i \) is partitioned as \( (x_i, z_i) \). The vector \( y_{2,i} \) contains the endogenous regressors.

Under multiplicative errors, the conditional mean of \( y_i \) is

\[
E(y_i|y_{2,i}, \tilde{z}_i) = E\{E(y_i|x_i, y_{2,i}, \epsilon_i)|y_{2,i}, \tilde{z}_i\} = E\{\exp(x_i'\beta_1 + y_{2,i}'\beta_2) \epsilon_i|y_{2,i}, \tilde{z}_i\} = \exp(x_i'\beta_1 + y_{2,i}'\beta_2) E(\epsilon_i|y_{2,i}, \tilde{z}_i)
\]
Under the CF estimator,

\[
E(\epsilon_i | y_{2,i}, \tilde{z}_i) = E \{E(\epsilon_i | v_i, c_i) | y_{2,i}, \tilde{z}_i\} \\
= E \{\exp(v_i'\rho + c_i) | y_{2,i}, \tilde{z}_i\} \\
= \exp \{(y_{2,i} - B\tilde{z}_i)'\rho\} E(c_i | y_{2,i}, \tilde{z}_i) \\
= \exp \{(y_{2,i} - B\tilde{z}_i)'\rho\}
\]

Thus under the CF estimator, we estimate the conditional mean of \(y_i\) as

\[
E(y_i | y_{2,i}, \tilde{z}_i) = \exp \left( x_i'\beta_1 + y_{2,i}'\beta_2 + (y_{2,i} - B\tilde{z}_i)'\rho \right)
\]

The CF estimator explicitly models the functional form of the endogeneity of \(y_{2,i}\) and \(\epsilon_i\) with the instruments and exogenous regressors \(\tilde{z}_i\). This allows it to correct the exponential-form estimator for the \(E(\epsilon_i | y_{2,i}, \tilde{z}_i)\) term.

In contrast, the GMM estimator does not model the functional form of the endogeneity of \(y_{2,i}\) and \(\epsilon_i\). Therefore, \(E(\epsilon_i | y_{2,i}, \tilde{z}_i)\) is not estimated, and the exponential-form estimator under GMM estimation simply ignores this term. Noting that because \(\tilde{z}_i\) and \(\epsilon_i\) are independent, \(E(\epsilon_i | y_{2,i}, \tilde{z}_i) = E(\epsilon_i | y_{2,i})\), we can obviously see that ignoring the term will lead to inconsistent estimation of the conditional mean of \(y_i\). \(y_{2,i}\) and \(\epsilon_i\) are not independent, so \(E(\epsilon_i | y_{2,i})\) may vary based on \(y_{2,i}\).

In the additive errors setting, a similar derivation will show that the exponential-form estimator obtained from GMM estimation is inconsistent for the conditional mean of \(y_i\).

[R] ivpoisson — Poisson model with continuous endogenous covariates

[U] 20 Estimation and postestimation commands
Description

`ivprobit` fits models for binary dependent variables where one or more of the covariates are endogenous and errors are normally distributed. By default, `ivprobit` uses maximum likelihood, but Newey’s (1987) minimum chi-squared (two-step) estimator can be requested. Both estimators assume that the endogenous covariates are continuous and so are not appropriate for use with discrete endogenous covariates.

Quick start

Probit regression of $y_1$ on $x$ and endogenous regressor $y_2$ that is instrumented using $z$

```
ivprobit y1 x (y2 = z)
```

With robust standard errors

```
ivprobit y1 x (y2 = z), vce(robust)
```

Use Newey’s two-step estimator

```
ivprobit y1 x (y2 = z), twostep
```

As above, and show first-stage regression results

```
ivprobit y1 x (y2 = z), twostep first
```

Menu

Statistics > Endogenous covariates > Probit model with continuous endogenous covariates
## Syntax

### Maximum likelihood estimator

```
ivprobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight] [, mle_options]
```

### Two-step estimator

```
ivprobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight], twostep [tse_options]
```

*varlist1* is the list of exogenous variables.

*varlist2* is the list of endogenous variables.

*varlistiv* is the list of exogenous variables used with *varlist1* as instruments for *varlist2*.

The following option is available with ivprobit but is not shown in the dialog box:
coeflegend; see [R] estimation options.

Options for two-step estimator

twostep is required and requests that Newey’s (1987) efficient two-step estimator be used to obtain the coefficient estimates.

asis requests that all specified variables and observations be retained in the maximization process. This option is typically not used and may introduce numerical instability. Normally, ivprobit drops any endogenous or exogenous variables that perfectly predict success or failure in the dependent variable. The associated observations are also dropped. For more information, see Model identification in [R] probit.

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (twostep) and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

level(#); see [R] estimation options.

first requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, first shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the probit equation. The default is not to show these parameter estimates.
ivprobit — Probit model with continuous endogenous covariates

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] estimation options.

The following option is available with ivprobit but is not shown in the dialog box: coeflegend; see [R] estimation options.

Remarks and examples

Remarks are presented under the following headings:

Model setup
Model identification

Model setup

ivprobit fits models with dichotomous dependent variables and endogenous covariates. You can use it to fit a probit model when you suspect that one or more of the covariates are correlated with the error term. ivprobit is to probit modeling what ivregress is to linear regression analysis; see [R] ivregress for more information.

Formally, the model is

\[ y_1^* = y_2 \beta + x_1 \gamma + u_i \]
\[ y_2 = x_1 \Pi_1 + x_2 \Pi_2 + v_i \]

where \( i = 1, \ldots, N \), \( y_2 \) is a \( 1 \times p \) vector of endogenous variables, \( x_1 \) is a \( 1 \times k \) vector of exogenous variables, \( x_2 \) is a \( 1 \times k_2 \) vector of additional instruments, and the equation for \( y_2 \) is written in reduced form. By assumption, \( (u_i, v_i) \sim N(0, \Sigma) \), where \( \sigma_{11} \) is normalized to one to identify the model. \( \beta \) and \( \gamma \) are vectors of structural parameters, and \( \Pi_1 \) and \( \Pi_2 \) are matrices of reduced-form parameters. This is a recursive model: \( y_2 \) appears in the equation for \( y_1^* \), but \( y_1^* \) does not appear in the equation for \( y_2 \). We do not observe \( y_1 \); instead, we observe

\[ y_{1i} = \begin{cases} 0 & y_{1i}^* < 0 \\ 1 & y_{1i}^* \geq 0 \end{cases} \]

The order condition for identification of the structural parameters requires that \( k_2 \geq p \). Presumably, \( \Sigma \) is not block diagonal between \( u_i \) and \( v_i \); otherwise, \( y_2 \) would not be endogenous.

Technical note

This model is derived under the assumption that \( (u_i, v_i) \) is independent and identically distributed multivariate normal for all \( i \). The vce(cluster clustvar) option can be used to control for a lack of independence. As with most probit models, if \( u_i \) is heteroskedastic, point estimates will be inconsistent.
Example 1

We have hypothetical data on 500 two-parent households, and we wish to model whether the woman is employed. We have a variable, `fem_work`, that is equal to one if she has a job and zero otherwise. Her decision to work is a function of the number of children at home (`kids`), number of years of schooling completed (`fem_educ`), and other household income measured in thousands of dollars (`other_inc`). We suspect that unobservable shocks affecting the woman’s decision to hold a job also affect the household’s other income. Therefore, we treat `other_inc` as endogenous. As an instrument, we use the number of years of schooling completed by the man (`male_educ`).

The syntax for specifying the exogenous, endogenous, and instrumental variables is identical to that used in `ivregress`; see [R] `ivregress` for details.

```

`ivprobit` used the default maximum likelihood estimator. The header of the output contains the sample size as well as a Wald statistic and $p$-value for the test of the hypothesis that all the slope coefficients are jointly zero. Below the table of coefficients, Stata reminds us that the endogenous variable is `other_inc` and that `fem_educ`, `kids`, and `male_educ` were used as instruments.

At the bottom of the output is a Wald test of the exogeneity of the instrumented variables. We reject the null hypothesis of no endogeneity. If there is no endogeneity, a standard probit regression would be preferable (see [R] `probit`).

Below we fit our model with Newey’s (1987) minimum chi-squared estimator using the `twostep` option.
Example 2

Refitting our labor-supply model with the two-step estimator yields

```
. ivprobit fem_work fem_educ kids (other_inc = male_educ), twostep
Checking reduced-form model...
```

Two-step probit with endogenous regressors

|                | Coef. | Std. Err. | z     | P>|z|  | [95% Conf. Interval] |
|----------------|-------|-----------|-------|-------|----------------------|
| other_inc      | -0.058473 | 0.0093364 | -6.26 | 0.000  | -0.0767719 -0.040174 |

Instrumented: other_inc
Instruments: fem_educ kids male_educ

Wald test of exogeneity: chi2(1) = 6.50  Prob > chi2 = 0.0108

All the coefficients have the same signs as their counterparts in the maximum likelihood model. The Wald test at the bottom of the output confirms our earlier finding of endogeneity.

Technical note

In a standard probit model, the error is assumed to have a variance of one. In the probit model with endogenous covariates, we assume that \((u_i, v_i)\) is multivariate normal with covariance matrix

\[
\text{Var}(u_i, v_i) = \Sigma = \begin{bmatrix} 1 & \Sigma_{21} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix}
\]

From the properties of the multivariate normal distribution, it follows that \(\text{Var}(u_i|v_i) = 1 - \Sigma_{22}^{-1}\Sigma_{21}\). Newey’s estimator and other two-step probit estimators yield estimates of \(\beta/\sigma\) and \(\gamma/\sigma\), where \(\sigma\) is the square root of \(\text{Var}(u_i|v_i)\), instead of estimates of \(\beta\) and \(\gamma\). Hence, we cannot directly compare the estimates obtained from Newey’s estimator with those obtained from maximum likelihood, which estimate \(\beta, \gamma,\) and \(\sigma\) separately. See Wooldridge (2010, 585–594) for a discussion about the interpretation of the estimates and the computation of marginal effects of two-step probit estimators under endogeneity.
Model identification

As in the linear simultaneous-equation model, the order condition for identification requires that the number of excluded exogenous variables (that is, the additional instruments) be at least as great as the number of included endogenous variables. `ivprobit` checks this for you and issues an error message if the order condition is not met.

Like `probit`, `logit`, and `logistic`, `ivprobit` checks the exogenous and endogenous variables to see if any of them predict the outcome variable perfectly. It will then drop offending variables and observations and fit the model on the remaining data. Instruments that are perfect predictors do not affect estimation, so they are not checked. See `Model identification` in [R] `probit` for more information.

`ivprobit` will also occasionally display messages such as

```
Note: 4 failures and 0 successes completely determined.
```

For an explanation of this message, see [R] `logit`.

Stored results

`ivprobit, mle` stores the following in `e()`:

Scalars

- `e(N)` number of observations
- `e(N_cds)` number of completely determined successes
- `e(N_cdf)` number of completely determined failures
- `e(k)` number of parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_aux)` number of auxiliary parameters
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(ll)` log likelihood
- `e(N_clust)` number of clusters
- `e(endog_ct)` number of endogenous covariates
- `e(p)` model Wald $p$-value
- `e(p_exog)` exogeneity test Wald $p$-value
- `e(chi2)` model Wald $\chi^2$
- `e(chi2_exog)` Wald $\chi^2$ test of exogeneity
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise
Macros

- `e(cmd)`  
  ivprobit

- `e(cmdline)`  
  command as typed

- `e(depvar)`  
  name of dependent variable

- `e(instd)`  
  instrumented variables

- `e(insts)`  
  instruments

- `e(wtype)`  
  weight type

- `e(wexp)`  
  weight expression

- `e(title)`  
  title in estimation output

- `e(clustvar)`  
  name of cluster variable

- `e(chi2type)`  
  Wald; type of model $\chi^2$ test

- `e(vce)`  
  vcetype specified in vce()

- `e(vcetype)`  
  title used to label Std. Err.

- `e(asis)`  
  asis, if specified

- `e(method)`  
  ml

- `e(opt)`  
  type of optimization

- `e(which)`  
  max or min; whether optimizer is to perform maximization or minimization

- `e(ml_method)`  
  type of ml method

- `e(user)`  
  name of likelihood-evaluator program

- `e(technique)`  
  maximization technique

- `e(properties)`  
  b V

- `e(estat_cmd)`  
  program used to implement estat

- `e(predict)`  
  program used to implement predict

- `e(footnote)`  
  program used to implement the footnote display

- `e(marginsok)`  
  predictions allowed by margins

- `e(asbalanced)`  
  factor variables fvset as asbalanced

- `e(asobserved)`  
  factor variables fvset as asobserved

Matrices

- `e(b)`  
  coefficient vector

- `e(Cns)`  
  constraints matrix

- `e(rules)`  
  information about perfect predictors

- `e(ilog)`  
  iteration log (up to 20 iterations)

- `e(gradient)`  
  gradient vector

- `e(Sigma)`  
  $\Sigma$

- `e(V)`  
  variance–covariance matrix of the estimators

- `e(V_modelbased)`  
  model-based variance

Functions

- `e(sample)`  
  marks estimation sample
ivprobit, twostep stores the following in e():

Methods and formulas

Fitting limited-dependent variable models with endogenous covariates has received considerable attention in the econometrics literature. Building on the results of Amemiya (1978, 1979), Newey (1987) developed an efficient method of estimation that encompasses both Rivers and Vuong’s (1988) simultaneous-equations probit model and Smith and Blundell’s (1986) simultaneous-equations tobit model. An efficient alternative to two-step estimation, and ivprobit’s default, is to use maximum likelihood. For compactness, we write the model as

\[
\begin{align*}
y_{1i}^* &= z_i \delta + u_i \\
y_{2i} &= x_i \Pi + v_i
\end{align*}
\]  

where \( z_i = (y_{2i}, x_{1i}) \), \( x_i = (x_{1i}, x_{2i}) \), \( \delta = (\beta', \gamma')' \), and \( \Pi = (\Pi_1', \Pi_2')' \).

Deriving the likelihood function is straightforward because we can write the joint density \( f(y_{1i}, y_{2i}, x_i) \) as \( f(y_{1i}|y_{2i}, x_i) f(y_{2i}|x_i) \). When there is an endogenous regressor, the log likelihood for observation \( i \) is
\[ \ln L_i = w_i \left[ y_{1i} \ln \Phi (m_i) + (1 - y_{1i}) \ln \{1 - \Phi (m_i)\} + \ln \phi \left( \frac{y_{2i} - x_i \Pi}{\sigma} \right) - \ln \sigma \right] \]

where

\[ m_i = \frac{z_i \delta + \rho (y_{2i} - x_i \Pi)}{(1 - \rho^2)^{\frac{1}{2}}} \]

\( \Phi(\cdot) \) and \( \phi(\cdot) \) are the standard normal distribution and density functions, respectively; \( \sigma \) is the standard deviation of \( v_i \); \( \rho \) is the correlation coefficient between \( u_i \) and \( v_i \); and \( w_i \) is the weight for observation \( i \) or one if no weights were specified. Instead of estimating \( \sigma \) and \( \rho \), we estimate \( \ln \sigma \) and \( \text{atanh} \, \rho \), where

\[ \text{atanh} \, \rho = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right) \]

For multiple endogenous covariates, let

\[ \text{Var}(u_i, v_i) = \Sigma = \begin{bmatrix} 1 & \Sigma'_{21} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix} \]

As in any probit model, we have imposed the normalization \( \text{Var}(u_i) = 1 \) to identify the model. The log likelihood for observation \( i \) is

\[ \ln L_i = w_i \left[ y_{1i} \ln \Phi (m_i) + (1 - y_{1i}) \ln \{1 - \Phi (m_i)\} + \ln f(y_{2i} | x_i) \right] \]

where

\[ \ln f(y_{2i} | x_i) = -\frac{p}{2} \ln 2\pi - \frac{1}{2} \ln |\Sigma_{22}| - \frac{1}{2} \left( y_{2i} - x_i \Pi \right) \Sigma_{22}^{-1} \left( y_{2i} - x_i \Pi \right)' \]

and

\[ m_i = \left( 1 - \Sigma'_{21} \Sigma_{22}^{-1} \Sigma_{21} \right)^{-\frac{1}{2}} \left\{ z_i \delta + (y_{2i} - x_i \Pi) \Sigma_{22}^{-1} \Sigma_{21} \right\} \]

With maximum likelihood estimation, this command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See \texttt{[P] _robust}, particularly \texttt{Maximum likelihood estimators} and \texttt{Methods and formulas}.

The maximum likelihood version of \texttt{ivprobit} also supports estimation with survey data. For details on VCEs with survey data, see \texttt{[SVY] variance estimation}.

The two-step estimates are obtained using Newey’s (1987) minimum chi-squared estimator. The reduced-form equation for \( y_{1i}^* \) is

\[ y_{1i}^* = (x_i \Pi + v_i) \beta + x_i \gamma + u_i \]

\[ = x_i \alpha + v_i \beta + u_i \]

\[ = x_i \alpha + \nu_i \]

where \( \nu_i = v_i \beta + u_i \). Because \( u_i \) and \( v_i \) are jointly normal, \( \nu_i \) is also normal. Note that

\[ \alpha = \begin{bmatrix} \Pi_1 \\ \Pi_2 \end{bmatrix} \beta + \begin{bmatrix} I \\ 0 \end{bmatrix} \gamma = D(\Pi) \delta \]
where $D(\Pi) = (\Pi, I_1)$ and $I_1$ is defined such that $x_i I_1 = x_{1i}$. Letting $\hat{\Pi} = (x_i \hat{\Pi}, x_{1i})$, $\hat{z}_i \delta = x_i D(\hat{\Pi}) \delta$, where $D(\hat{\Pi}) = (\hat{\Pi}, I_1)$. Thus one estimator of $\alpha$ is $D(\hat{\Pi}) \delta$; denote this estimator by $\hat{D}\delta$.

$\alpha$ could also be estimated directly as the solution to

$$\max_{\alpha, \lambda} \sum_{i=1}^{N} l(y_{1i}, x_i \alpha + \hat{v}_i \lambda)$$

(2)

where $l(\cdot)$ is the log likelihood for probit. Denote this estimator by $\tilde{\alpha}$. The inclusion of the $\hat{v}_i \lambda$ term follows because the multivariate normality of $(u_i, v_i)$ implies that, conditional on $y_{2i}$, the expected value of $u_i$ is nonzero. Because $v_i$ is unobservable, the least-squares residuals from fitting (1b) are used.

Amemiya (1978) shows that the estimator of $\delta$ defined by

$$\max_{\delta, \lambda} (\tilde{\alpha} - \hat{D}\delta)' \hat{\Omega}^{-1} (\tilde{\alpha} - \hat{D}\delta)$$

where $\hat{\Omega}$ is a consistent estimator of the covariance of $\sqrt{N}(\tilde{\alpha} - \hat{D}\delta)$, is asymptotically efficient relative to all other estimators that minimize the distance between $\tilde{\alpha}$ and $D(\hat{\Pi}) \delta$. Thus an efficient estimator of $\delta$ is

$$\hat{\delta} = (\hat{D}' \hat{\Omega}^{-1} \hat{D})^{-1} \hat{D}' \hat{\Omega}^{-1} \tilde{\alpha}$$

(3)

and

$$\text{Var}(\delta) = (\hat{D}' \hat{\Omega}^{-1} \hat{D})^{-1}$$

(4)

To implement this estimator, we need $\hat{\Omega}^{-1}$.

Consider the two-step maximum likelihood estimator that results from first fitting (1b) by OLS and computing the residuals $\hat{v}_i = y_{2i} - x_i \hat{\Pi}$. The estimator is then obtained by solving

$$\max_{\delta, \lambda} \sum_{i=1}^{N} l(y_{1i}, z_i \delta + \hat{v}_i \lambda)$$

This is the two-step instrumental variables (2SIV) estimator proposed by Rivers and Vuong (1988), and its role will become apparent shortly.

From Proposition 5 of Newey (1987), $\sqrt{N}(\tilde{\alpha} - \hat{D}\delta) \xrightarrow{d} N(0, \Omega)$, where

$$\Omega = J^{-1}_{\alpha \alpha} + (\lambda - \beta)' \Sigma_{22} (\lambda - \beta) Q^{-1}$$

and $\Sigma_{22} = E\{v_i' v_i\}$. $J^{-1}_{\alpha \alpha}$ is simply the covariance matrix of $\tilde{\alpha}$, ignoring that $\hat{\Pi}$ is an estimated parameter matrix. Moreover, Newey shows that the covariance matrix from an OLS regression of $y_{2i}(\hat{\lambda} - \beta)$ on $x_i$ is a consistent estimator of the second term. $\hat{\lambda}$ can be obtained from solving (2), and the 2SIV estimator yields a consistent estimate, $\hat{\beta}$.

Mechanically, estimation proceeds in several steps.

1. Each of the endogenous right-hand-side variables is regressed on all the exogenous variables, and the fitted values and residuals are calculated. The matrix $\hat{D} = D(\hat{\Pi})$ is assembled from the estimated coefficients.
2. \texttt{probit} is used to solve (2) and obtain $\tilde{\alpha}$ and $\hat{\lambda}$. The portion of the covariance matrix corresponding to $\alpha$, $J_{\alpha\alpha}^{-1}$, is also saved.

3. The 2SIV estimator is evaluated, and the parameters $\hat{\beta}$ corresponding to $y_{2i}$ are collected.

4. $y_{2i}(\hat{\lambda} - \hat{\beta})$ is regressed on $x_i$. The covariance matrix of the parameters from this regression is added to $J_{\alpha\alpha}^{-1}$, yielding $\hat{\Omega}$.

5. Evaluating (3) and (4) yields the estimates $\hat{\delta}$ and $\text{Var}(\hat{\delta})$.

6. A Wald test of the null hypothesis $H_0 : \lambda = 0$, using the 2SIV estimates, serves as our test of exogeneity.

The two-step estimates are not directly comparable to those obtained from the maximum likelihood estimator or from \texttt{probit}. The argument is the same for Newey’s efficient estimator as for Rivers and Vuong’s (1988) 2SIV estimator, so we consider the simpler 2SIV estimator. From the properties of the normal distribution,

$$E(u_i|v_i) = v_i \Sigma_{22}^{-1} \Sigma_{21}$$

and

$$\text{Var}(u_i|v_i) = 1 - \Sigma_{21}' \Sigma_{22}^{-1} \Sigma_{21}$$

We write $u_i$ as $u_i = v_i \Sigma_{22}^{-1} \Sigma_{21} + e_i = v_i \lambda + e_i$, where $e_i \sim N(0, 1 - \rho^2)$, $\rho^2 = \Sigma_{21}' \Sigma_{22}^{-1} \Sigma_{21}$, and $e_i$ is independent of $v_i$. In the second stage of 2SIV, we use a probit regression to estimate the parameters of

$$y_{1i} = z_i \delta + v_i \lambda + e_i$$

Because $v_i$ is unobservable, we use the sample residuals from the first-stage regressions.

$$\Pr(y_{1i} = 1|z_i, v_i) = \Pr(z_i \delta + v_i \lambda + e_i > 0|z_i, v_i) = \Phi \left\{ (1 - \rho^2)^{-\frac{1}{2}} (z_i \delta + v_i \lambda) \right\}$$

Hence, as mentioned previously, 2SIV and Newey’s estimator do not estimate $\delta$ and $\lambda$ but rather

$$\delta_{\rho} = \frac{1}{(1 - \rho^2)^{\frac{1}{2}}} \delta$$

and

$$\lambda_{\rho} = \frac{1}{(1 - \rho^2)^{\frac{1}{2}}} \lambda$$

Acknowledgments

The two-step estimator is based on the \texttt{probitiv} command written by Jonah Gelbach of the Department of Economics at Yale University and the \texttt{ivprobit} command written by Joe Harkness of the Institute of Policy Studies at Johns Hopkins University.

Postestimation commands

The following postestimation commands are of special interest after `ivprobit`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>estat classification</code></td>
<td>report various summary statistics, including the classification table</td>
</tr>
<tr>
<td><code>estat correlation</code></td>
<td>report the correlation matrix of the errors of the dependent variable and the endogenous variables</td>
</tr>
<tr>
<td><code>estat covariance</code></td>
<td>report the covariance matrix of the errors of the dependent variable and the endogenous variables</td>
</tr>
<tr>
<td><code>lroc</code></td>
<td>compute area under ROC curve and graph the curve</td>
</tr>
<tr>
<td><code>lsens</code></td>
<td>graph sensitivity and specificity versus probability cutoff</td>
</tr>
</tbody>
</table>

These commands are not appropriate after the two-step estimator or the `svy` prefix.

The following standard postestimation commands are also available:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>contrast</code></td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td><code>estat ic</code></td>
<td>Akaike’s and Schwarz’s Bayesian information criteria (AIC and BIC)</td>
</tr>
<tr>
<td><code>estat summarize</code></td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td><code>estat vce</code></td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td><code>estat (svy)</code></td>
<td>postestimation statistics for survey data</td>
</tr>
<tr>
<td><code>estimates</code></td>
<td>cataloging estimation results</td>
</tr>
<tr>
<td><code>forecast</code></td>
<td>dynamic forecasts and simulations</td>
</tr>
<tr>
<td><code>hausman</code></td>
<td>Hausman’s specification test</td>
</tr>
<tr>
<td><code>lincom</code></td>
<td>point estimates, standard errors, testing, and inference for linear combinations of coefficients</td>
</tr>
<tr>
<td><code>lrtest</code></td>
<td>likelihood-ratio test; not available with two-step estimator</td>
</tr>
<tr>
<td><code>margins</code></td>
<td>marginal means, predictive margins, marginal effects, and average marginal effects</td>
</tr>
<tr>
<td><code>marginsplot</code></td>
<td>graph the results from margins (profile plots, interaction plots, etc.)</td>
</tr>
<tr>
<td><code>nlcom</code></td>
<td>point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients</td>
</tr>
<tr>
<td><code>predict</code></td>
<td>predictions, residuals, influence statistics, and other diagnostic measures</td>
</tr>
<tr>
<td><code>predictnl</code></td>
<td>point estimates, standard errors, testing, and inference for generalized predictions</td>
</tr>
<tr>
<td><code>pwcompare</code></td>
<td>pairwise comparisons of estimates</td>
</tr>
<tr>
<td><code>suest</code></td>
<td>seemingly unrelated estimation</td>
</tr>
<tr>
<td><code>test</code></td>
<td>Wald tests of simple and composite linear hypotheses</td>
</tr>
<tr>
<td><code>testnl</code></td>
<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

* `estat ic`, `forecast`, and `suest` are not appropriate after `ivprobit, twostep`.
† `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.
predict

Description for predict

predict creates a new variable containing predictions such as linear predictions, standard errors, and probabilities.

Menu for predict

Statistics  >  Postestimation

Syntax for predict

After ML or twostep

    predict [type] newvar [if] [in] [ , statistic rules asif ]

After ML

    predict [type] { stub* | newvarlist } [if] [in] , scores

statistic    Description

Main
xb           linear prediction; the default
stdp         standard error of the linear prediction
pr           probability of a positive outcome accounting for endogeneity; not available
              with two-step estimator

These statistics are available both in and out of sample; type predict . . . if e(sample) . . . if wanted only for the estimation sample.

Options for predict

xb, the default, calculates the linear prediction.

stdp calculates the standard error of the linear prediction.

pr calculates the probability of a positive outcome accounting for endogeneity. pr is not available with the two-step estimator.

rules requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations. rules is not available with the two-step estimator.

asif requests that Stata ignore the rules and the exclusion criteria and calculate predictions for all observations possible using the estimated parameters from the model. asif is not available with the two-step estimator.
scores, not available with two-step, calculates equation-level score variables. For models with one endogenous regressor, four new variables are created.

The first new variable will contain $\frac{\partial \ln L}{\partial (z_i \delta)}$.

The second new variable will contain $\frac{\partial \ln L}{\partial (x_i \Pi)}$.

The third new variable will contain $\frac{\partial \ln L}{\partial \text{atanh} \ \rho}$.

The fourth new variable will contain $\frac{\partial \ln L}{\partial \ln \sigma}$.

For models with $p$ endogenous regressors, $p + \{(p + 1)(p + 2)\}/2$ new variables are created.

The first new variable will contain $\frac{\partial \ln L}{\partial (z_i \delta)}$.

The second through $(p + 1)$th new variables will contain $\frac{\partial \ln L}{\partial (x_i \Pi_k)}$, $k = 1, \ldots, p$, where $\Pi_k$ is the $k$th column of $\Pi$.

The remaining score variables will contain the partial derivatives of $\ln L$ with respect to $s_{21}$, $s_{31}$, $s_{p+1, 1}$, $s_{22}$, $s_{p+1, 2}$, $\ldots$, $s_{p+1, p+1}$, where $s_{m,n}$ denotes the $(m,n)$ element of the Cholesky decomposition of the error covariance matrix.

**margins**

**Description for margins**

`margins` estimates margins of response for linear predictions and probabilities.

**Menu for margins**

Statistics > Postestimation

**Syntax for margins**

```
margins [marginlist] [ , options ]
margins [marginlist], predict(statistic ...) [ predict(statistic ...) ... ] [ options ]
```

<table>

Statistics not allowed with `margins` are functions of stochastic quantities other than $e(b)$. For the full syntax, see `[R] margins`. 
estat

Description for estat

   estat correlation displays the correlation matrix of the errors of the dependent variable and the endogenous variables.

   estat covariance displays the covariance matrix of the errors of the dependent variable and the endogenous variables.

   estat correlation and estat covariance are not allowed after the ivprobit two-step estimator.

Menu for estat

   Statistics > Postestimation

Syntax for estat

   Correlation matrix

   estat correlation [, border(bspec) left(#) format(%fmt)]

   Covariance matrix

   estat correlation [, border(bspec) left(#) format(%fmt)]

Options for estat

border(bspec) sets border style of the matrix display. The default is border(all).
left(#) sets the left indent of the matrix display. The default is left(2).
format(%fmt) specifies the format for displaying the individual elements of the matrix. The default is format(%9.0g).

Remarks and examples

   Remarks are presented under the following headings:

   Marginal effects
   Obtaining predicted values
Marginal effects

Example 1

We can obtain marginal effects by using the `margins` command after `ivprobit`. We will calculate average marginal effects by using the labor-supply model of example 1 in [R] `ivprobit`.

```
. use http://www.stata-press.com/data/r14/laborsup
. ivprobit fem_work fem_educ kids (other_inc = male_educ)
   (output omitted)
. margins, dydx(*) predict(pr)
```

```
Average marginal effects Number of obs = 500
Model VCE : OIM
Expression : Probability of positive outcome, predict(pr)
dy/dx w.r.t. : other_inc fem_educ kids male_educ

| dy/dx      | Std. Err. | z    | P>|z|  | [95% Conf. Interval] |
|------------|-----------|------|------|---------------------|
| other_inc  | -.0097802 | .0014994 | -6.52 | 0.000     | -.012719 | -.0068414 |
| fem_educ   | .0623273  | .007099  | 8.78  | 0.000     | .0484135 | .076241   |
| kids       | -.0614265 | .0139446 | -4.41 | 0.000     | -.0887574 | -.0340956 |
| male_educ  | -.0194406 | .0022103 | -8.80 | 0.000     | -.0237728 | -.0151084 |
```

Here we see that a $1,000 increase in `other_inc` leads to an average decrease of 0.01 in the probability that the woman has a job. `male_educ` has no effect because it appears only as an instrument.

Obtaining predicted values

After fitting your model with `ivprobit`, you can obtain the linear prediction and its standard error for both the estimation sample and other samples by using the `predict` command; see [U] 20 Estimation and postestimation commands and [R] `predict`. If you had used the maximum likelihood estimator, you could also obtain the probability of a positive outcome.

`predict`’s `pr` option calculates the probability of a positive outcome, remembering any rules used to identify the model, and calculates missing for excluded observations. `predict`’s `rules` option uses the rules in predicting probabilities, whereas `predict`’s `asif` option ignores both the rules and the exclusion criteria and calculates probabilities for all possible observations by using the estimated parameters from the model. See Obtaining predicted values in [R] `probit postestimation` for an example.

Methods and formulas

The linear prediction is calculated as $z_i \tilde{\delta}$, where $\tilde{\delta}$ is the estimated value of $\delta$, and $z_i$ and $\delta$ are defined in (1a) of [R] `ivprobit`. The probability of a positive outcome is $\Phi(m_i)$, where $\Phi(\cdot)$ is the standard normal distribution function and $m_i$ is defined in Methods and formulas of [R] `ivprobit`. Using $m_i$ instead of $z_i \tilde{\delta}$ to evaluate $\Phi(\cdot)$ accounts for endogeneity.

[U] 20 Estimation and postestimation commands
**ivregress** fits linear models where one or more of the regressors are endogenously determined. **ivregress** supports estimation via two-stage least squares (2SLS), limited-information maximum likelihood (LIML), and generalized method of moments (GMM).

### Quick start

2SLS estimation of a linear regression of $y_1$ on $x_1$ and endogenous regressor $y_2$ that is instrumented by $z_1$

```
ivregress 2sls y1 x1 (y2 = z1)
```

As above, but with two endogenous regressors, $y_2$ and $y_3$ instrumented by $z_1$ and $z_2$

```
ivregress 2sls y1 x1 (y2 y3 = z1 z2)
```

With robust standard errors

```
ivregress 2sls y1 x1 (y2 y3 = z1 z2), vce(robust)
```

Report small-sample statistics

```
ivregress 2sls y1 x1 (y2 y3 = z1 z2), small
```

Use LIML estimation

```
ivregress liml y1 x1 (y2 y3 = z1 z2)
```

Use GMM estimation

```
ivregress gmm y1 x1 (y2 y3 = z1 z2)
```

Also specify a weighting matrix that allows for correlation within clusters identified by `cvar`

```
ivregress gmm y1 x1 (y2 y3 = z1 z2), wmatrix(cluster cvar)
```

### Menu

- **Statistics** > **Endogenous covariates** > **Single-equation instrumental-variables regression**
**Syntax**

```
ivregress estimator depvar [ varlist1 ] ( varlist2 = varlistiv ) [ if ] [ in ] [ weight ]
    [ , options ]
```

*varlist1* is the list of exogenous variables.

*varlist2* is the list of endogenous variables.

*varlistiv* is the list of exogenous variables used with *varlist1* as instruments for *varlist2*.

**Model**

- **noconstant** suppress constant term
- **hascons** has user-supplied constant

**GMM**

- **wmatrix(wmtype)** *wmtype* may be `robust`, `cluster clustvar`, `hac kernel`, or `unadjusted`
- **center** center moments in weight matrix computation
- **igmm** use iterative instead of two-step GMM estimator
- **eps(#)²** specify # for parameter convergence criterion; default is `eps(1e-6)`
- **weps(#)²** specify # for weight matrix convergence criterion; default is `weps(1e-6)`
- **optimization_options²** control the optimization process; seldom used

**SE/Robust**

- **vce(vcetype)** *vcetype* may be `unadjusted`, `robust`, `cluster clustvar`, `bootstrap`, `jackknife`, or `hac kernel`  

**Reporting**

- **level(#)** set confidence level; default is `level(95)`
- **first** report first-stage regression
- **small** make degrees-of-freedom adjustments and report small-sample statistics
- **noheader** display only the coefficient table
- **depname(depname)** substitute dependent variable name
- **eform(string)** report exponentiated coefficients and use *string* to label them
- **display_options** control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
### perfect
Do not check for collinearity between endogenous regressors and excluded instruments.

### coeflegend
Display legend instead of statistics.

---

1. These options may be specified only when `gmm` is specified.
2. These options may be specified only when `igmm` is specified.

*varlist1*, `varlist2`, and `varlist3` may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, `varlist1`, `varlist2`, and `varlist3` may contain time-series operators; see [U] 11.4.4 Time-series varlists.

*bootstrap*, `by`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`aweights` are not allowed with the `jackknife` prefix; see [R] `jackknife`.

`hascons`, `vce()`, `noheader`, and `depname()` are allowed; see [R] `svy`.

`aweights`, `fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.

`perfect` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

---

**Options**

#### Model

- **noconstant**: see [R] `estimation options`.

  `hascons` indicates that a user-defined constant or its equivalent is specified among the independent variables.

#### GMM

- **wmatrix(wmtype)** specifies the type of weighting matrix to be used in conjunction with the GMM estimator.

  Specifying `wmatrix(robust)` requests a weighting matrix that is optimal when the error term is heteroskedastic. `wmatrix(robust)` is the default.

  Specifying `wmatrix(cluster clustvar)` requests a weighting matrix that accounts for arbitrary correlation among observations within clusters identified by `clustvar`.

  Specifying `wmatrix(hac kernel #)` requests a heteroskedasticity- and autocorrelation-consistent (HAC) weighting matrix using the specified kernel (see below) with # lags. The bandwidth of a kernel is equal to `# + 1`.

  Specifying `wmatrix(hac kernel opt [ # ])` requests an HAC weighting matrix using the specified kernel, and the lag order is selected using Newey and West’s (1994) optimal lag-selection algorithm. `#` is an optional tuning parameter that affects the lag order selected; see the discussion in Methods and formulas.

  Specifying `wmatrix(hac kernel)` requests an HAC weighting matrix using the specified kernel and `N - 2` lags, where `N` is the sample size.

There are three kernels available for HAC weighting matrices, and you may request each one by using the name used by statisticians or the name perhaps more familiar to economists:

- `bartlett` or `newest` requests the Bartlett (Newey–West) kernel;
- `parzen` or `gallant` requests the Parzen (Gallant 1987) kernel; and
- `quadraticspectral` or `andrews` requests the quadratic spectral (Andrews 1991) kernel.
ivregress — Single-equation instrumental-variables regression

Specifying `wmatrix(unadjusted)` requests a weighting matrix that is suitable when the errors are homoskedastic. The GMM estimator with this weighting matrix is equivalent to the 2SLS estimator. `center` requests that the sample moments be centered (demeaned) when computing GMM weight matrices. By default, centering is not done.

`igmm` requests that the iterative GMM estimator be used instead of the default two-step GMM estimator. Convergence is declared when the relative change in the parameter vector from one iteration to the next is less than `eps()` or the relative change in the weight matrix is less than `weps()`.

`eps(#)` specifies the convergence criterion for successive parameter estimates when the iterative GMM estimator is used. The default is `eps(1e-6)`. Convergence is declared when the relative difference between successive parameter estimates is less than `eps()` and the relative difference between successive estimates of the weighting matrix is less than `weps()`.

`weps(#)` specifies the convergence criterion for successive estimates of the weighting matrix when the iterative GMM estimator is used. The default is `weps(1e-6)`. Convergence is declared when the relative difference between successive parameter estimates is less than `eps()` and the relative difference between successive estimates of the weighting matrix is less than `weps()`.

`optimization_options: iterate(#), [no]log. iterate()` specifies the maximum number of iterations to perform in conjunction with the iterative GMM estimator. The default is 16,000 or the number set using `set maxiter` (see [R] maximize). `log/nolog` specifies whether to show the iteration log. These options are seldom used.

`vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap, jackknife`); see [R] `vce_option`.

`vce(unadjusted)`, the default for 2sls and liml, specifies that an unadjusted (nonrobust) VCE matrix be used. The default for `gmm` is based on the `wmtype` specified in the `wmatrix()` option; see `wmatrix(wmtype)` above. If `wmatrix()` is specified with `gmm` but `vce()` is not, then `vcetype` is set equal to `wmtype`. To override this behavior and obtain an unadjusted (nonrobust) VCE matrix, specify `vce(unadjusted)`.

ivregress also allows the following:

`vce(hac kernel [# opt [#]])` specifies that an HAC covariance matrix be used. The syntax used with `vce(hac kernel ...)` is identical to that used with `wmatrix(hac kernel ...)`; see `wmatrix(wmtype)` above.

`level(#); see [R] estimation options.`

`first` requests that the first-stage regression results be displayed.

`small` requests that the degrees-of-freedom adjustment \( N/(N-k) \) be made to the variance–covariance matrix of parameters and that small-sample \( F \) and \( t \) statistics be reported, where \( N \) is the sample size and \( k \) is the number of parameters estimated. By default, no degrees-of-freedom adjustment is made, and Wald and \( z \) statistics are reported. Even with this option, no degrees-of-freedom adjustment is made to the weighting matrix when the GMM estimator is used.

`noheader` suppresses the display of the summary statistics at the top of the output, displaying only the coefficient table.
depname is used only in programs and ado-files that use ivregress to fit models other than instrumental-variables regression. depname() may be specified only at estimation time. depname() is recorded as the identity of the dependent variable, even though the estimates are calculated using depvar. This method affects the labeling of the output—not the results calculated—but could affect later calculations made by predict, where the residual would be calculated as deviations from depname rather than depvar. depname() is most typically used when depvar is a temporary variable (see [P] macro) used as a proxy for depname.

eform(string) is used only in programs and ado-files that use ivregress to fit models other than instrumental-variables regression. eform() specifies that the coefficient table be displayed in “exponentiated form”, as defined in [R] maximize, and that string be used to label the exponentiated coefficients in the table.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] estimation options.

The following options are available with ivregress but are not shown in the dialog box:

perfect requests that ivregress not check for collinearity between the endogenous regressors and excluded instruments, allowing one to specify “perfect” instruments. This option cannot be used with the LIML estimator. This option may be required when using ivregress to implement other estimators.

coefflegend; see [R] estimation options.

Remarks and examples

ivregress performs instrumental-variables regression and weighted instrumental-variables regression. For a general discussion of instrumental variables, see Baum (2006), Cameron and Trivedi (2005; 2010, chap. 6) Davidson and MacKinnon (1993), Greene (2012, chap. 8), and Wooldridge (2010, 2016). See Hall (2005) for a lucid presentation of GMM estimation. Angrist and Pischke (2009, chap. 4) offer a casual yet thorough introduction to instrumental-variables estimators, including their use in estimating treatment effects. Some of the earliest work on simultaneous systems can be found in Cowles Commission monographs—Koopmans and Marschak (1950) and Koopmans and Hood (1953)—with the first developments of 2SLS appearing in Theil (1953) and Basmann (1957). However, Stock and Watson (2015, 427–429) present an example of the method of instrumental variables that was first published in 1928 by Philip Wright.

The syntax for ivregress assumes that you want to fit one equation from a system of equations or an equation for which you do not want to specify the functional form for the remaining equations of the system. To fit a full system of equations, using either 2SLS equation-by-equation or three-stage least squares, see [R] reg3. An advantage of ivregress is that you can fit one equation of a multiple-equation system without specifying the functional form of the remaining equations.

Formally, the model fit by ivregress is

\[ y_i = y_i \beta_1 + x_{1i} \beta_2 + u_i \]  \hspace{1cm} (1)
\[ y_i = x_{1i} \Pi_1 + x_{2i} \Pi_2 + v_i \]  \hspace{1cm} (2)

Here \( y_i \) is the dependent variable for the \( i \)th observation, \( y_i \) represents the endogenous regressors (varlist2 in the syntax diagram), \( x_{1i} \) represents the included exogenous regressors (varlist1 in the syntax diagram), and \( x_{2i} \) represents the excluded exogenous regressors (varlistiv in the syntax diagram). \( x_{1i} \) and \( x_{2i} \) are collectively called the instruments. \( u_i \) and \( v_i \) are zero-mean error terms, and the correlations between \( u_i \) and the elements of \( v_i \) are presumably nonzero.
The rest of the discussion is presented under the following headings:

- 2SLS and LIML estimators
- GMM estimator
- Video example

### 2SLS and LIML estimators

The most common instrumental-variables estimator is 2SLS.

#### Example 1: 2SLS estimator

We have state data from the 1980 census on the median dollar value of owner-occupied housing (**hsngval**) and the median monthly gross rent (**rent**). We want to model **rent** as a function of **hsngval** and the percentage of the population living in urban areas (**pcturban**):

\[
rent_i = \beta_0 + \beta_1 hsngval_i + \beta_2 pcturban_i + u_i
\]

where \(i\) indexes states and \(u_i\) is an error term.

Because random shocks that affect rental rates in a state probably also affect housing values, we treat **hsngval** as endogenous. We believe that the correlation between **hsngval** and **u** is not equal to zero. On the other hand, we have no reason to believe that the correlation between **pcturban** and **u** is nonzero, so we assume that **pcturban** is exogenous.

Because we are treating **hsngval** as an endogenous regressor, we must have one or more additional variables available that are correlated with **hsngval** but uncorrelated with **u**. Moreover, these excluded exogenous variables must not affect **rent** directly, because if they do then they should be included in the regression equation we specified above. In our dataset, we have a variable for family income (**faminc**) and for region of the country (**region**) that we believe are correlated with **hsngval** but not the error term. Together, **pcturban**, **faminc**, and factor variables **2.region**, **3.region**, and **4.region** constitute our set of instruments.

To fit the equation in Stata, we specify the dependent variable and the list of included exogenous variables. In parentheses, we specify the endogenous regressors, an equal sign, and the excluded exogenous variables. Only the additional exogenous variables must be specified to the right of the equal sign; the exogenous variables that appear in the regression equation are automatically included as instruments.

Here we fit our model with the 2SLS estimator:

```
. use http://www.stata-press.com/data/r14/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
Instrumental variables (2SLS) regression Number of obs = 50
Wald chi2(2) = 90.76
Prob > chi2 = 0.0000
R-squared = 0.5989
Root MSE = 22.166

rent Coef. Std. Err. z P>|z| [95% Conf. Interval]
hsngval .0022398 .0003284 6.82 0.000 .0015961 .0028836
pcturban .081516 .2987652 0.27 0.785 -.504053 .667085
_cons 120.7065 15.22839 7.93 0.000 90.85942 150.5536

Instrumented: hsngval
Instruments: pcturban faminc 2.region 3.region 4.region
```
As we would expect, states with higher housing values have higher rental rates. The proportion of a state’s population that is urban does not have a significant effect on rents.

### Technical note

In a simultaneous-equations framework, we could write the model we just fit as

\[ \text{hsngval}_i = \pi_0 + \pi_1 \text{faminc}_i + \pi_2 2.\text{region}_i + \pi_3 3.\text{region}_i + \pi_4 4.\text{region}_i + v_i \]

\[ \text{rent}_i = \beta_0 + \beta_1 \text{hsngval}_i + \beta_2 \text{pcturban}_i + u_i \]

which here happens to be recursive (triangular), because hsngval appears in the equation for rent but rent does not appear in the equation for hsngval. In general, however, systems of simultaneous equations are not recursive. Because this system is recursive, we could fit the two equations individually via OLS if we were willing to assume that \( u \) and \( v \) were independent. For a more detailed discussion of triangular systems, see Kmenta (1997, 719–720).

Historically, instrumental-variables estimation and systems of simultaneous equations were taught concurrently, and older textbooks describe instrumental-variables estimation solely in the context of simultaneous equations. However, in recent decades, the treatment of endogeneity and instrumental-variables estimation has taken on a much broader scope, while interest in the specification of complete systems of simultaneous equations has waned. Most recent textbooks, such as Cameron and Trivedi (2005), Davidson and MacKinnon (1993), and Wooldridge (2010, 2016), treat instrumental-variables estimation as an integral part of the modern economists’ toolkit and introduce it long before shorter discussions on simultaneous equations.

In addition to the 2SLS member of the \( \kappa \)-class estimators, \texttt{ivregress} implements the LIML estimator. Both theoretical and Monte Carlo exercises indicate that the LIML estimator may yield less bias and confidence intervals with better coverage rates than the 2SLS estimator. See Poi (2006) and Stock, Wright, and Yogo (2002) (and the papers cited therein) for Monte Carlo evidence.

#### Example 2: LIML estimator

Here we refit our model with the LIML estimator:

```
. ivregress liml rent pcturban (hsngval = faminc i.region)
```

| rent | Coef. | Std. Err. | z  | P>|z| | [95% Conf. Interval] |
|------|-------|-----------|----|------|----------------------|
| hsgval | .0026686 | .0004173 | 6.39 | 0.000 | .0018507 .0034865 |
| pcturban | -.1827391 | .3571132 | -0.51 | 0.609 | -.8826681 .5171899 |
| _cons | 117.6087 | 17.22625 | 6.83 | 0.000 | 83.84587 151.3715 |

Instrumented: hsgval

Instruments: pcturban faminc 2.region 3.region 4.region

These results are qualitatively similar to the 2SLS results, although the coefficient on hsgval is about 19% higher.
GMM estimator

Since the celebrated paper of Hansen (1982), the GMM has been a popular method of estimation in economics and finance, and it lends itself well to instrumental-variables estimation. The basic principle is that we have some moment or orthogonality conditions of the form

\[ E(z_i u_i) = 0 \]  
\[ (3) \]

From (1), we have \( u_i = y_i - y_i \beta_1 - x_{1i} \beta_2 \). What are the elements of the instrument vector \( z_i \)? By assumption, \( x_{1i} \) is uncorrelated with \( u_i \), as are the excluded exogenous variables \( x_{2i} \), and so we use \( z_i = [x_{1i}, x_{2i}] \). The moment conditions are simply the mathematical representation of the assumption that the instruments are exogenous—that is, the instruments are orthogonal to (uncorrelated with) \( u_i \).

If the number of elements in \( z_i \) is just equal to the number of unknown parameters, then we can apply the analogy principle to (3) and solve

\[ \frac{1}{N} \sum_i z_i u_i = \frac{1}{N} \sum_i z_i (y_i - y_i \beta_1 - x_{1i} \beta_2) = 0 \]  
\[ (4) \]

This equation is known as the method of moments estimator. Here where the number of instruments equals the number of parameters, the method of moments estimator coincides with the 2SLS estimator, which also coincides with what has historically been called the indirect least-squares estimator (Judge et al. 1985, 595).

The “generalized” in GMM addresses the case in which the number of instruments (columns of \( z_i \)) exceeds the number of parameters to be estimated. Here there is no unique solution to the population moment conditions defined in (3), so we cannot use (4). Instead, we define the objective function

\[ Q(\beta_1, \beta_2) = \left( \frac{1}{N} \sum_i z_i u_i \right)^T W \left( \frac{1}{N} \sum_i z_i u_i \right) \]  
\[ (5) \]

where \( W \) is a positive-definite matrix with the same number of rows and columns as the number of columns of \( z_i \). \( W \) is known as the weighting matrix, and we specify its structure with the \texttt{wmatrix()} option. The GMM estimator of \((\beta_1, \beta_2)\) minimizes \( Q(\beta_1, \beta_2) \); that is, the GMM estimator chooses \( \beta_1 \) and \( \beta_2 \) to make the moment conditions as close to zero as possible for a given \( W \). For a more general GMM estimator, see \texttt{[R] gmm}. \texttt{gmm} does not restrict you to fitting a single linear equation, though the syntax is more complex.

A well-known result is that if we define the matrix \( S_0 \) to be the covariance of \( z_i u_i \) and set \( W = S_0^{-1} \), then we obtain the optimal two-step GMM estimator, where by optimal estimator we mean the one that results in the smallest variance given the moment conditions defined in (3).

Suppose that the errors \( u_i \) are heteroskedastic but independent among observations. Then

\[ S_0 = E(z_i u_i u_i' z_i') = E(u_i^2 z_i z_i') \]

and the sample analogue is

\[ \hat{S} = \frac{1}{N} \sum_i \hat{u}_i^2 z_i z_i' \]  
\[ (6) \]

To implement this estimator, we need estimates of the sample residuals \( \hat{u}_i \). \texttt{ivregress gmm} obtains the residuals by estimating \( \beta_1 \) and \( \beta_2 \) by 2SLS and then evaluates (6) and sets \( W = \hat{S}^{-1} \). Equation (6) is the same as the center term of the “sandwich” robust covariance matrix available from most Stata estimation commands through the \texttt{vce(robust)} option.
Example 3: GMM estimator

Here we refit our model of rents by using the GMM estimator, allowing for heteroskedasticity in $u_i$:

```stata
.ivregress gmm rent pcturban (hsngval = faminc i.region), wmatrix(robust)
```

```
Instrumental variables (GMM) regression
Number of obs = 50
Wald chi2(2) = 112.09
Prob > chi2 = 0.0000
R-squared = 0.6616

GMM weight matrix: Robust
Root MSE = 20.358

|          | Robust Coef. | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|----------|--------------|-----------|------|-----|---------------------|
| hsngval  | 0.0014643    | 0.0004473 | 3.27 | 0.001| 0.0005877 0.002341  |
| pcturban | 0.7615482    | 0.2895105 | 2.63 | 0.009| 0.1941181 1.328978  |
| _cons    | 112.1227     | 10.80234  | 10.38| 0.000| 90.95052 133.2949  |

Instrumented: hsngval
Instruments: pcturban faminc 2.region 3.region 4.region
```

Because we requested that a heteroskedasticity-consistent weighting matrix be used during estimation but did not specify the `vce()` option, `ivregress` reported standard errors that are robust to heteroskedasticity. Had we specified `vce(unadjusted)`, we would have obtained standard errors that would be correct only if the weighting matrix $W$ does in fact converge to $S_0^{-1}$.

Technical note

Many software packages that implement GMM estimation use the same heteroskedasticity-consistent weighting matrix we used in the previous example to obtain the optimal two-step estimates but do not use a heteroskedasticity-consistent VCE, even though they may label the standard errors as being “robust”. To replicate results obtained from other packages, you may have to use the `vce(unadjusted)` option. See Methods and formulas below for a discussion of robust covariance matrix estimation in the GMM framework.

By changing our definition of $S_0$, we can obtain GMM estimators suitable for use with other types of data that violate the assumption that the errors are independent and identically distributed. For example, you may have a dataset that consists of multiple observations for each person in a sample. The observations that correspond to the same person are likely to be correlated, and the estimation technique should account for that lack of independence. Say that in your dataset, people are identified by the variable `personid` and you type

```stata
.ivregress gmm ..., wmatrix(cluster personid)
```

Here `ivregress` estimates $S_0$ as

$$\hat{S} = \frac{1}{N} \sum_{c \in C} q_c q_c'$$

where $C$ denotes the set of clusters and

$$q_c = \sum_{i \in c_j} \hat{u}_i z_i$$
where $c_j$ denotes the $j$th cluster. This weighting matrix accounts for the within-person correlation among observations, so the GMM estimator that uses this version of $S_0$ will be more efficient than the estimator that ignores this correlation.

### Example 4: GMM estimator with clustering

We have data from the National Longitudinal Survey on young women’s wages as reported in a series of interviews from 1968 through 1988, and we want to fit a model of wages as a function of each woman’s age and age squared, job tenure, birth year, and level of education. We believe that random shocks that affect a woman’s wage also affect her job tenure, so we treat tenure as endogenous. As additional instruments, we use her union status, number of weeks worked in the past year, and a dummy indicating whether she lives in a metropolitan area. Because we have several observations for each woman (corresponding to interviews done over several years), we want to control for clustering on each person.

```plaintext
use http://www.stata-press.com/data/r14/nlswork
(National Longitudinal Survey. Young Women 14-26 years of age in 1968)
.ivregress gmm ln_wage age c.age#c.age birth_yr grade (tenure = union wks_work msp), wmatrix(cluster idcode)
Instrumental variables (GMM) regression
Number of obs = 18,625
Wald chi2(5) = 1807.17
Prob > chi2 = 0.0000
R-squared = .
GMM weight matrix: Cluster (idcode)
Root MSE = .46951

(Std. Err. adjusted for 4,110 clusters in idcode)

|         | Coef.     | Std. Err. | z    | P>|z|    | [95% Conf. Interval] |

Instrumented: tenure
Instruments: age c.age#c.age birth_yr grade union wks_work msp

Both job tenure and years of schooling have significant positive effects on wages.

Time-series data are often plagued by serial correlation. In these cases, we can construct a weighting matrix to account for the fact that the error in period $t$ is probably correlated with the errors in periods $t-1$, $t-2$, etc. An HAC weighting matrix can be used to account for both serial correlation and potential heteroskedasticity.

To request an HAC weighting matrix, you specify the `wmatrix(hac kernel [#|opt])` option. `kernel` specifies which of three kernels to use: `bartlett`, `parzen`, or `quadraticspectral`. `kernel` determines the amount of weight given to lagged values when computing the HAC matrix, and `#` denotes the maximum number of lags to use. Many texts refer to the bandwidth of the kernel instead of the number of lags; the bandwidth is equal to the number of lags plus one. If neither `opt` nor `#` is specified, then $N-2$ lags are used, where $N$ is the sample size.
If you specify `wmatrix(hac kernel opt)`, then `ivregress` uses Newey and West’s (1994) algorithm for automatically selecting the number of lags to use. Although the authors’ Monte Carlo simulations do show that the procedure may result in size distortions of hypothesis tests, the procedure is still useful when little other information is available to help choose the number of lags.

For more on GMM estimation, see Baum (2006); Baum, Schaffer, and Stillman (2003, 2007); Cameron and Trivedi (2005); Davidson and MacKinnon (1993); Hayashi (2000); or Wooldridge (2010). See Newey and West (1987) and Wang and Wu (2012) for an introduction to HAC covariance matrix estimation.

**Video example**

Instrumental variables regression using Stata

**Stored results**

`ivregress` stores the following in `e()`:

**Scalars**

- `e(N)` number of observations
- `e(mss)` model sum of squares
- `e(df_m)` model degrees of freedom
- `e(rss)` residual sum of squares
- `e(df_r)` residual degrees of freedom
- `e(r2)` $R^2$
- `e(r2_a)` adjusted $R^2$
- `e(F)` $F$ statistic
- `e(rmse)` root mean squared error
- `e(N_clust)` number of clusters
- `e(chi2)` $χ^2$
- `e(kappa)` $κ$ used in LIML estimator
- `e(J)` value of GMM objective function
- `e(wlagopt)` lags used in HAC weight matrix (if Newey–West algorithm used)
- `e(vcelagopt)` lags used in HAC VCE matrix (if Newey–West algorithm used)
- `e(rank)` rank of `e(V)`
- `e(iterations)` number of GMM iterations (0 if not applicable)

**Macros**

- `e(cmd)` `ivregress`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(instd)` instrumented variable
- `e(insts)` instruments
- `e(constant)` noconstant or hasconstant if specified
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(hac_kernel)` HAC kernel
- `e(hac_lag)` HAC lag
- `e(vce)` vcetype specified in `vce()`
- `e(vcetype)` title used to label Std. Err.
- `e(_estimator)` 2sls, liml, or `gmm`
- `e(exogr)` exogenous regressors
- `e(wmatrix)` wmtype specified in `wmatrix()`
- `e(moment)` centered if `centered` specified
- `e(small)` small if small-sample statistics
- `e(depname)` `depname` if `depname(depname)` specified; otherwise same as `e(depvar)`
- `e(properties)` `b V`
Methods and formulas

Methods and formulas are presented under the following headings:

Notation
2SLS and LIML estimators
GMM estimator

Notation

Items printed in lowercase and italicized (for example, \( x \)) are scalars. Items printed in lowercase and boldfaced (for example, \( \mathbf{x} \)) are vectors. Items printed in uppercase and boldfaced (for example, \( \mathbf{X} \)) are matrices.

The model is

\[
\begin{align*}
\mathbf{y} &= \mathbf{Y}\boldsymbol{\beta}_1 + \mathbf{X}_1\boldsymbol{\beta}_2 + \mathbf{u} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u} \\
\mathbf{Y} &= \mathbf{X}_1\mathbf{\Pi}_1 + \mathbf{X}_2\mathbf{\Pi}_2 + \mathbf{v} = \mathbf{Z}\mathbf{\Pi} + \mathbf{V}
\end{align*}
\]

where \( \mathbf{y} \) is an \( N \times 1 \) vector of the left-hand-side variable; \( N \) is the sample size; \( \mathbf{Y} \) is an \( N \times p \) matrix of \( p \) endogenous regressors; \( \mathbf{X}_1 \) is an \( N \times k_1 \) matrix of \( k_1 \) included exogenous regressors; \( \mathbf{X}_2 \) is an \( N \times k_2 \) matrix of \( k_2 \) excluded exogenous variables, \( \mathbf{X} = [\mathbf{Y} \mathbf{X}_1], \mathbf{Z} = [\mathbf{X}_1 \mathbf{X}_2]; \mathbf{u} \) is an \( N \times 1 \) vector of errors; \( \mathbf{V} \) is an \( N \times p \) matrix of errors; \( \boldsymbol{\beta} = [\boldsymbol{\beta}_1 \boldsymbol{\beta}_2] \) is a \( k = (p + k_1) \times 1 \) vector of parameters; and \( \mathbf{\Pi} \) is a \( (k_1 + k_2) \times p \) vector of parameters. If a constant term is included in the model, then one column of \( \mathbf{X}_1 \) contains all ones.

Let \( \mathbf{v} \) be a column vector of weights specified by the user. If no weights are specified, \( \mathbf{v} = 1 \). Let \( \mathbf{w} \) be a column vector of normalized weights. If no weights are specified or if the user specified \fweights \ or \iweights, \( \mathbf{w} = \mathbf{v} \); otherwise, \( \mathbf{w} = \{\mathbf{v}/(1'\mathbf{v})\}(1'1) \). Let \( \mathbf{D} \) denote the \( N \times N \) matrix with \( \mathbf{w} \) on the main diagonal and zeros elsewhere. If no weights are specified, \( \mathbf{D} \) is the identity matrix.

The weighted number of observations \( n \) is defined as \( 1'\mathbf{w} \). For \iweights, this is truncated to an integer. The sum of the weights is \( 1'\mathbf{v} \). Define \( c = 1 \) if there is a constant in the regression and zero otherwise.

The order condition for identification requires that \( k_2 \geq p \); the number of excluded exogenous variables must be at least as great as the number of endogenous regressors.

In the following formulas, if weights are specified, \( \mathbf{X}_1'\mathbf{D}\mathbf{X}_1, \mathbf{X}'\mathbf{X}, \mathbf{X}'\mathbf{y}, \mathbf{y}'\mathbf{y}, \mathbf{Z}'\mathbf{Z}, \mathbf{Z}'\mathbf{X}, \) and \( \mathbf{Z}'\mathbf{y} \) are replaced with \( \mathbf{X}_1'\mathbf{D}\mathbf{X}_1, \mathbf{X}'\mathbf{D}\mathbf{X}, \mathbf{X}'\mathbf{D}\mathbf{y}, \mathbf{y}'\mathbf{D}\mathbf{y}, \mathbf{Z}'\mathbf{D}\mathbf{Z}, \mathbf{Z}'\mathbf{D}\mathbf{X}, \) and \( \mathbf{Z}'\mathbf{D}\mathbf{y} \), respectively. We suppress the \( \mathbf{D} \) below to simplify the notation.
2SLS and LIML estimators

Define the $\kappa$-class estimator of $\beta$ as

$$b = \{X'(I - \kappa M_Z)X\}^{-1}X'(I - \kappa M_Z)y$$

where $M_Z = I - Z(Z'Z)^{-1}Z'$. The 2SLS estimator results from setting $\kappa = 1$. The LIML estimator results from selecting $\kappa$ to be the minimum eigenvalue of $(Y'M_ZY)^{-1/2}Y'M_{X_1}Y(Y'M_ZY)^{-1/2}$, where $M_{X_1} = I - X_1(X_1'X_1)^{-1}X_1'$.

The total sum of squares (TSS) equals $y'y$ if there is no intercept and $y'y - \{(1'y)^2/n\}$ otherwise. The degrees of freedom is $n - c$. The error sum of squares (ESS) is defined as $y'y - 2bX'y + b'X'Xb$. The model sum of squares (MSS) equals TSS - ESS. The degrees of freedom is $k - c$.

The mean squared error, $s^2$, is defined as $\text{ESS}/(n - k)$ if small is specified and $\text{ESS}/n$ otherwise. The root mean squared error is $s$, its square root.

If $c = 1$ and small is not specified, a Wald statistic, $W$, of the joint significance of the $k - 1$ parameters of $\beta$ except the constant term is calculated; $W \sim \chi^2(k - 1)$. If $c = 1$ and small is specified, then an $F$ statistic is calculated as $F = W/(k - 1); F \sim F(k - 1, n - k)$.

The $R$-squared is defined as $R^2 = 1 - \text{ESS}/\text{TSS}$.

The adjusted $R$-squared is $R^2_a = 1 - (1 - R^2)(n - c)/(n - k)$.

The unadjusted (default) variance estimate is $\text{Var}(b) = s^2\{X'(I - \kappa M_Z)X\}^{-1}$.

For a general discussion of robust variance estimates in regression, see A general notation for the robust variance calculation in [R] regress. ivregress uses the same definitions for terms discussed in Robust calculation for regress in its robust variance calculation, except for the following.

The vector of scores is given by

$$u_j = (y_j - x_jb)\hat{x}_j$$

where $\hat{x}_j' = Pz_j'$ and $P = (X'Z)(Z'Z)^{-1}$. When the formulas in [R] regress are applied, $q_c$ is given by its regressionlike definition. If small is not specified, then $k = 0$ in the formulas given in [R] regress.

ivregress 2sls and ivregress liml also support estimation with survey data. For details on VCEs with survey data, see [SVY] variance estimation.

GMM estimator

We obtain an initial consistent estimate of $\beta$ by using the 2SLS estimator; see above. Using this estimate of $\beta$, we compute the weighting matrix $W$ and calculate the GMM estimator

$$b_{GMM} = \{X'ZWZ'X\}^{-1}X'ZWZ'y$$

The variance of $b_{GMM}$ is

$$\text{Var}(b_{GMM}) = n\{X'ZWZ'X\}^{-1}X'ZW\hat{W}ZW'X\{X'ZWZ'X\}^{-1}$$

$\text{Var}(b_{GMM})$ is of the sandwich form DMD; see [P] _robust. If the user specifies the small option, ivregress implements a small-sample adjustment by multiplying the VCE by $N/(N - k)$.  

1126  ivregress — Single-equation instrumental-variables regression
If \( \text{vce(adjusted)} \) is specified, then we set \( \hat{S} = W^{-1} \) and the VCE reduces to the “optimal” GMM variance estimator

\[
\text{Var}(\beta_{GMM}) = n\{X'ZWZ'X\}^{-1}
\]

However, if \( W^{-1} \) is not a good estimator of \( E(z_iu_iu'_i) \), then the optimal GMM estimator is inefficient, and inference based on the optimal variance estimator could be misleading.

\( W \) is calculated using the residuals from the initial 2SLS estimates, whereas \( S \) is estimated using the residuals based on \( b_{GMM} \). The \text{wmatrix()} option affects the form of \( W \), whereas the \text{vce()} option affects the form of \( S \). Except for different residuals being used, the formulas for \( W^{-1} \) and \( S \) are identical, so we focus on estimating \( W^{-1} \).

If \text{wmatrix(unadjusted)} is specified, then

\[
W^{-1} = \frac{s^2}{n} \sum_i z_i z'_i
\]

where \( s^2 = \sum_i u_i^2/n \). This weight matrix is appropriate if the errors are homoskedastic.

If \text{wmatrix(robust)} is specified, then

\[
W^{-1} = \frac{1}{n} \sum_i u_i^2 z_i z'_i
\]

which is appropriate if the errors are heteroskedastic.

If \text{wmatrix(cluster clustvar)} is specified, then

\[
W^{-1} = \frac{1}{n} \sum_c q_c q'_c
\]

where \( c \) indexes clusters,

\[
q_c = \sum_{i \in c_j} u_i z_i
\]

and \( c_j \) denotes the \( j \)th cluster.

If \text{wmatrix(hac kernel [#])} is specified, then

\[
W^{-1} = \frac{1}{n} \sum_i u_i^2 z_i z'_i + \frac{1}{n} \sum_{l=1}^{n-1} \sum_{i=n}^{i=n-l} K(l, m) u_i u_{i-l} (z_i z'_{i-l} + z_{i-l} z'_{i-l})
\]

where \( m = \# \) if \( \# \) is specified and \( m = n - 2 \) otherwise. Define \( z = l/(m + 1) \). If \text{kernel} is \text{nwest}, then

\[
K(l, m) = \begin{cases} 
1 - z & 0 \leq z \leq 1 \\
0 & \text{otherwise}
\end{cases}
\]

If \text{kernel} is \text{gallant}, then

\[
K(l, m) = \begin{cases} 
1 - 6z^2 + 6z^3 & 0 \leq z \leq 0.5 \\
2(1 - z)^3 & 0.5 < z \leq 1 \\
0 & \text{otherwise}
\end{cases}
\]
If \textit{kernel} is \textit{quadraticspectral}, then

\[
K(l, m) = \begin{cases} 
1 & z = 0 \\
3 \left\{ \sin(\theta)/\theta - \cos(\theta) \right\} / \theta^2 & \text{otherwise}
\end{cases}
\]

where \( \theta = 6\pi z/5 \).

If \textit{wmatrix(hac kernel opt)} is specified, then \textsc{ivregress} uses Newey and West’s (1994) automatic lag-selection algorithm, which proceeds as follows. Define \( \mathbf{h} \) to be a \((k_1 + k_2) \times 1\) vector containing ones in all rows except for the row corresponding to the constant term (if present); that row contains a zero. Define

\[
f_i = (u_i z_i) \mathbf{h} \\
\hat{\sigma}_j = \frac{1}{n} \sum_{i=j+1}^{n} f_i f_{i-j} \quad j = 0, \ldots, m^* \\
\hat{s}(q) = 2 \sum_{j=1}^{m^*} \hat{\sigma}_j j^q \\
\hat{s}(0) = \hat{\sigma}_0 + 2 \sum_{j=1}^{m^*} \hat{\sigma}_j \\
\hat{\gamma} = c_\gamma \left\{ \frac{\hat{s}(q)}{\hat{s}(0)} \right\}^{1/2q+1} \\
m = \hat{\gamma} n^{1/(2q+1)}
\]

where \( q, m^*, \) and \( c_\gamma \) depend on the kernel specified:

<table>
<thead>
<tr>
<th>Kernel</th>
<th>( q )</th>
<th>( m^* )</th>
<th>( c_\gamma )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bartlett</td>
<td>1</td>
<td>\text{int}\left{ \frac{20(T/100)^{2/9}}{} \right}</td>
<td>1.1447</td>
</tr>
<tr>
<td>Parzen</td>
<td>2</td>
<td>\text{int}\left{ \frac{20(T/100)^{4/25}}{} \right}</td>
<td>2.6614</td>
</tr>
<tr>
<td>Quadratic spectral</td>
<td>2</td>
<td>\text{int}\left{ \frac{20(T/100)^{2/25}}{} \right}</td>
<td>1.3221</td>
</tr>
</tbody>
</table>

where \text{int}(x) denotes the integer obtained by truncating \( x \) toward zero. For the Bartlett and Parzen kernels, the optimal lag is \( \min\{\text{int}(m), m^*\} \). For the quadratic spectral, the optimal lag is \( \min\{m, m^*\} \).

If \textit{wmatrix(hac kernel opt #)} is specified, then \textsc{ivregress} uses \# instead of 20 in the definition of \( m^* \) above to select the optimal lag.

If \textit{center} is specified, when computing weighting matrices \textsc{ivregress} replaces the term \( u_i z_i \) in the formulas above with \( u_i z_i - \overline{uZ} \), where \( \overline{uZ} = \sum_i u_i z_i / N \).

Postestimation commands

The following postestimation commands are of special interest after `ivregress`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>estat endogenous</code></td>
<td>perform tests of endogeneity</td>
</tr>
<tr>
<td><code>estat firststage</code></td>
<td>report “first-stage” regression statistics</td>
</tr>
<tr>
<td><code>estat overid</code></td>
<td>perform tests of overidentifying restrictions</td>
</tr>
<tr>
<td><code>* estat sbknown</code></td>
<td>perform tests for a structural break with a known break date</td>
</tr>
<tr>
<td><code>* estat single</code></td>
<td>perform tests for a structural break with an unknown break date</td>
</tr>
</tbody>
</table>

These commands are not appropriate after the `svy` prefix.

* `estat sbknown` and `estat sbsingle` work only after `ivregress 2sls`.

The following postestimation commands are also available:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>contrast</code></td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td><code>estat summarize</code></td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td><code>estat vce</code></td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td><code>estat (svy) estimates</code></td>
<td>postestimation statistics for survey data</td>
</tr>
<tr>
<td><code>forecast</code></td>
<td>dynamic forecasts and simulations</td>
</tr>
<tr>
<td><code>hausman</code></td>
<td>Hausman’s specification test</td>
</tr>
<tr>
<td><code>lincom</code></td>
<td>point estimates, standard errors, testing, and inference for linear combinations of coefficients</td>
</tr>
<tr>
<td><code>margins</code></td>
<td>marginal means, predictive margins, marginal effects, and average marginal effects</td>
</tr>

</tr>
<tr>
<td><code>predict</code></td>
<td>predictions, residuals, influence statistics, and other diagnostic measures</td>
</tr>
<tr>
<td><code>predictnl</code></td>
<td>point estimates, standard errors, testing, and inference for generalized predictions</td>
</tr>
<tr>
<td><code>pwcompare</code></td>
<td>pairwise comparisons of estimates</td>
</tr>
<tr>
<td><code>test</code></td>
<td>Wald tests of simple and composite linear hypotheses</td>
</tr>
<tr>
<td><code>testnl</code></td>
<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

† `forecast` and `hausman` are not appropriate with `svy` estimation results.
predict

Description for predict

predict creates a new variable containing predictions such as linear predictions, residuals, standard errors, probabilities, and expected values.

Menu for predict

Statistics > Postestimation

Syntax for predict

\[ \text{predict [type] newvar [if] [in]} [\text{, statistic}] \]

\[ \text{predict [type]} \{ stub\* newvarlist \} [\text{if} [\text{in}]], \text{scores} \]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{xb}</td>
<td>linear prediction; the default</td>
</tr>
<tr>
<td>\text{residuals}</td>
<td>residuals</td>
</tr>
<tr>
<td>\text{stdp}</td>
<td>standard error of the prediction</td>
</tr>
<tr>
<td>\text{stdf}</td>
<td>standard error of the forecast</td>
</tr>
<tr>
<td>\text{pr}(a,b)</td>
<td>\text{Pr}(a &lt; y_j &lt; b) under exogeneity and normal errors</td>
</tr>
<tr>
<td>\text{e}(a,b)</td>
<td>\text{E}(y_j</td>
</tr>
<tr>
<td>\text{ystar}(a,b)</td>
<td>\text{E}(y_j^<em>), y_j^</em> = \max{a, \min(y_j, b)} under exogeneity and normal errors</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type \text{predict ... if e(sample) ... if} wanted only for the estimation sample.

\text{stdf} is not allowed with \text{svy} estimation results.

where \(a\) and \(b\) may be numbers or variables; \(a\) missing \((a \geq .)\) means \(-\infty\), and \(b\) missing \((b \geq .)\) means \(+\infty\); see [U] 12.2.1 Missing values.

Options for predict

\[ \text{xb, the default, calculates the linear prediction.} \]
\[ \text{residuals calculates the residuals, that is, } y_j - \mathbf{x}_j \mathbf{b}. \text{ These are based on the estimated equation when the observed values of the endogenous variables are used—not the projections of the instruments onto the endogenous variables.} \]
\[ \text{stdp calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation’s covariate pattern. This is also referred to as the standard error of the fitted value.} \]
\[ \text{stdf calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by stdf are always larger than those produced by stdp; see Methods and formulas in [R] regress postestimation.} \]
\( \text{pr}(a, b) \) calculates \( \Pr(a < x_j b + u_j < b) \), the probability that \( y_j | x_j \) would be observed in the interval \((a, b)\) under exogeneity and assuming errors are normally distributed.

\( a \) and \( b \) may be specified as numbers or variable names; \( lb \) and \( ub \) are variable names; \( \text{pr}(20, 30) \) calculates \( \Pr(20 < x_j b + u_j < 30) \); \( \text{pr}(lb, ub) \) calculates \( \Pr(lb < x_j b + u_j < ub) \); and \( \text{pr}(20, ub) \) calculates \( \Pr(20 < x_j b + u_j < ub) \).

\( a \) missing (\( a \geq . \)) means \(-\infty\); \( \text{pr}(., 30) \) calculates \( \Pr(-\infty < x_j b + u_j < 30) \); \( \text{pr}(lb, 30) \) calculates \( \Pr(-\infty < x_j b + u_j < 30) \) in observations for which \( lb \geq . \) and calculates \( \Pr(lb < x_j b + u_j < 30) \) elsewhere.

\( b \) missing (\( b \geq . \)) means \(+\infty\); \( \text{pr}(20, .) \) calculates \( \Pr(+\infty > x_j b + u_j > 20) \); \( \text{pr}(20, ub) \) calculates \( \Pr(+\infty > x_j b + u_j > 20) \) in observations for which \( ub \geq . \) and calculates \( \Pr(20 < x_j b + u_j < ub) \) elsewhere.

\( e(a, b) \) calculates \( E(x_j b + u_j | a < x_j b + u_j < b) \), the expected value of \( y_j | x_j \) conditional on \( y_j | x_j \) being in the interval \((a, b)\), meaning that \( y_j | x_j \) is truncated. \( a \) and \( b \) are specified as they are for \( \text{pr}(.) \). Exogeneity and normally distributed errors are assumed.

\( \text{ystar}(a, b) \) calculates \( E(y_j^* \mid x_j b + u_j \leq a, y_j^* = b \mid x_j b + u_j \geq b, y_j^* = x_j b + u_j \) otherwise, meaning that \( y_j^* \) is censored. \( a \) and \( b \) are specified as they are for \( \text{pr}(.) \). Exogeneity and normally distributed errors are assumed.

\( \text{scores} \) calculates the scores for the model. A new score variable is created for each endogenous regressor, as well as an equation-level score that applies to all exogenous variables and constant term (if present).
margins

Description for margins

margins estimates margins of response for linear predictions, probabilities, and expected values.

estat

Description for estat

    estat endogenous performs tests to determine whether endogenous regressors in the model are in fact exogenous. After GMM estimation, the $C$ (difference-in-Sargan) statistic is reported. After 2SLS estimation with an unadjusted VCE, the Durbin (1954) and Wu–Hausman (Wu 1974; Hausman 1978) statistics are reported. After 2SLS estimation with a robust VCE, Wooldridge’s (1995) robust score test and a robust regression-based test are reported. In all cases, if the test statistic is significant, then the variables being tested must be treated as endogenous. estat endogenous is not available after LIML estimation.

    estat firststage reports various statistics that measure the relevance of the excluded exogenous variables. By default, whether the equation has one or more than one endogenous regressor determines what statistics are reported.

    estat overid performs tests of overidentifying restrictions. If the 2SLS estimator was used, Sargan’s (1958) and Basmann’s (1960) $\chi^2$ tests are reported, as is Wooldridge’s (1995) robust score test; if the LIML estimator was used, Anderson and Rubin’s (1950) $\chi^2$ test and Basmann’s $F$ test are reported; and if the GMM estimator was used, Hansen’s (1982) $J$ statistic $\chi^2$ test is reported. A statistically significant test statistic always indicates that the instruments may not be valid.

Statistics  >  Postestimation

Syntax for estat

    Perform tests of endogeneity

    estat endogenous [ varlist ] [ , lags(#) forceweights forcenonrobust ]

    Report “first-stage” regression statistics

    estat firststage [ , all forcenonrobust ]

    Perform tests of overidentifying restrictions

    estat overid [ , lags(#) forceweights forcenonrobust ]

Options for estat

    Options for estat are presented under the following headings:

    Options for estat endogenous
    Options for estat firststage
    Options for estat overid
Options for estat endogenous

`lags(#)` specifies the number of lags to use for prewhitening when computing the heteroskedasticity-and autocorrelation-consistent (HAC) version of the score test of endogeneity. Specifying `lags(0)` requests no prewhitening. This option is valid only when the model was fit via 2SLS and an HAC covariance matrix was requested when the model was fit. The default is `lags(1)`.

`forceweights` requests that the tests of endogeneity be computed even though `aweights`, `pweights`, or `iweights` were used in the previous estimation. By default, these tests are conducted only after unweighted or frequency-weighted estimation. The reported critical values may be inappropriate for weighted data, so the user must determine whether the critical values are appropriate for a given application.

`forceonnonrobust` requests that the Durbin and Wu–Hausman tests be performed after 2SLS estimation even though a robust VCE was used at estimation time. This option is available only if the model was fit by 2SLS.

Options for estat firststage

`all` requests that all first-stage goodness-of-fit statistics be reported regardless of whether the model contains one or more endogenous regressors. By default, if the model contains one endogenous regressor, then the first-stage $R^2$, adjusted $R^2$, partial $R^2$, and $F$ statistics are reported, whereas if the model contains multiple endogenous regressors, then Shea’s partial $R^2$ and adjusted partial $R^2$ are reported instead.

`forceonnonrobust` requests that the minimum eigenvalue statistic and its critical values be reported even though a robust VCE was used at estimation time. The reported critical values assume that the errors are independent and identically distributed (i.i.d.) normal, so the user must determine whether the critical values are appropriate for a given application.

Options for estat overid

`lags(#)` specifies the number of lags to use for prewhitening when computing the heteroskedasticity-and autocorrelation-consistent (HAC) version of the score test of overidentifying restrictions. Specifying `lags(0)` requests no prewhitening. This option is valid only when the model was fit via 2SLS and an HAC covariance matrix was requested when the model was fit. The default is `lags(1)`.

`forceweights` requests that the tests of overidentifying restrictions be computed even though `aweights`, `pweights`, or `iweights` were used in the previous estimation. By default, these tests are conducted only after unweighted or frequency-weighted estimation. The reported critical values may be inappropriate for weighted data, so the user must determine whether the critical values are appropriate for a given application.

`forceonnonrobust` requests that the Sargan and Basmann tests of overidentifying restrictions be performed after 2SLS or LIML estimation even though a robust VCE was used at estimation time. These tests assume that the errors are i.i.d. normal, so the user must determine whether the critical values are appropriate for a given application.
Remarks and examples

Remarks are presented under the following headings:

- `estat endogenous`
- `estat firststage`
- `estat overid`

### estat endogenous

A natural question to ask is whether a variable presumed to be endogenous in the previously fit model could instead be treated as exogenous. If the endogenous regressors are in fact exogenous, then the OLS estimator is more efficient; and depending on the strength of the instruments and other factors, the sacrifice in efficiency by using an instrumental-variables estimator can be significant. Thus, unless an instrumental-variables estimator is really needed, OLS should be used instead. `estat endogenous` provides several tests of endogeneity after 2SLS and GMM estimation.

#### Example 1

In example 1 of [R] `ivregress`, we fit a model of the average rental rate for housing in a state as a function of the percentage of the population living in urban areas and the average value of houses. We treated `hsngval` as endogenous because unanticipated shocks that affect rental rates probably affect house prices as well. We used family income and region dummies as additional instruments for `hsngval`. Here we test whether we could treat `hsngval` as exogenous.

```stata
use http://www.stata-press.com/data/r14/hsng
(1980 Census housing data)
.ivregress 2sls rent pcturban (hsngval = faminc i.region) 
(output omitted)
.estat endogenous

Tests of endogeneity
Ho: variables are exogenous

Durbin (score) chi2(1) = 12.8473 (p = 0.0003)
Wu–Hausman F(1,46) = 15.9067 (p = 0.0002)
```

Because we did not specify any variable names after the `estat endogenous` command, Stata by default tested all the endogenous regressors (namely, `hsngval`) in our model. The null hypothesis of the Durbin and Wu–Hausman tests is that the variable under consideration can be treated as exogenous. Here both test statistics are highly significant, so we reject the null of exogeneity; we must continue to treat `hsngval` as endogenous.

The difference between the Durbin and Wu–Hausman tests of endogeneity is that the former uses an estimate of the error term’s variance based on the model assuming the variables being tested are exogenous, while the latter uses an estimate of the error variance based on the model assuming the variables being tested are endogenous. Under the null hypothesis that the variables being tested are exogenous, both estimates of the error variance are consistent. What we label the Wu–Hausman statistic is Wu’s (1974) “$T_2$” statistic, which Hausman (1978) showed can be calculated very easily via linear regression. Baum, Schaffer, and Stillman (2003, 2007) provide a lucid discussion of these tests.

When you fit a model with multiple endogenous regressors, you can test the exogeneity of a subset of the regressors while continuing to treat the others as endogenous. For example, say you have three endogenous regressors, $y_1$, $y_2$, and $y_3$, and you fit your model by typing

```stata
.ivregress depvar ... (y1 y2 y3 = ...)
```
Suppose you are confident that $y_1$ must be treated as endogenous, but you are undecided about $y_2$ and $y_3$. To test whether $y_2$ and $y_3$ can be treated as exogenous, you would type

```
    . estat endogenous y2 y3
```

The Durbin and Wu–Hausman tests assume that the error term is i.i.d. Therefore, if you requested a robust VCE at estimation time, `estat endogenous` will instead report Wooldridge’s (1995) score test and a regression-based test of exogeneity. Both these tests can tolerate heteroskedastic and autocorrelated errors, while only the regression-based test is amenable to clustering.

➢ Example 2

We refit our housing model, requesting robust standard errors, and then test the exogeneity of `hsngval`:

```
    . use http://www.stata-press.com/data/r14/hsng
      (1980 Census housing data)
    . ivregress 2sls rent pcturban (hsngval = faminc i.region), vce(robust)
      (output omitted)
    . estat endogenous
```

Tests of endogeneity
Ho: variables are exogenous

Robust score chi2(1) = 2.10428 (p = 0.1469)
Robust regression F(1,46) = 4.31101 (p = 0.0435)

Wooldridge’s score test does not reject the null hypothesis that `hsngval` is exogenous at conventional significance levels ($p = 0.1469$). However, the regression-based test does reject the null hypothesis at the 5% significance level ($p = 0.0435$). Typically, these two tests yield the same conclusion; the fact that our dataset has only 50 observations could be contributing to the discrepancy. Here we would be inclined to continue to treat `hsngval` as endogenous. Even if `hsngval` is exogenous, the 2SLS estimates are still consistent. On the other hand, if `hsngval` is in fact endogenous, the OLS estimates would not be consistent. Moreover, as we will see in our discussion of the `estat overid` command, our additional instruments may be invalid. To test whether an endogenous variable can be treated as exogenous, we must have a valid set of instruments to use to fit the model in the first place!

Unlike the Durbin and Wu–Hausman tests, Wooldridge’s score and the regression-based tests do not allow you to test a subset of the endogenous regressors in the model; you can test only whether all the endogenous regressors are in fact exogenous.

After GMM estimation, `estat endogenous` calculates what Hayashi (2000, 220) calls the $C$ statistic, also known as the difference-in-Sargan statistic. The $C$ statistic can be made robust to heteroskedasticity, autocorrelation, and clustering; and the version reported by `estat endogenous` is determined by the weight matrix requested via the `wmatrix()` option used when fitting the model with `ivregress`. Additionally, the test can be used to determine the exogeneity of a subset of the endogenous regressors, regardless of the type of weight matrix used.

If you fit your model using the LIML estimator, you can use the `hausman` command to carry out a traditional Hausman (1978) test between the OLS and LIML estimates.
For an excluded exogenous variable to be a valid instrument, it must be sufficiently correlated with the included endogenous regressors but uncorrelated with the error term. In recent decades, researchers have paid considerable attention to the issue of instruments that are only weakly correlated with the endogenous regressors. In such cases, the usual 2SLS, GMM, and LIML estimators are biased toward the OLS estimator, and inference based on the standard errors reported by, for example, ivregress can be severely misleading. For more information on the theory behind instrumental-variables estimation with weak instruments, see Nelson and Startz (1990); Staiger and Stock (1997); Hahn and Hausman (2003); the survey article by Stock, Wright, and Yogo (2002); and Angrist and Pischke (2009, chap. 4).

When the instruments are only weakly correlated with the endogenous regressors, some Monte Carlo evidence suggests that the LIML estimator performs better than the 2SLS and GMM estimators; see, for example, Poi (2006) and Stock, Wright, and Yogo (2002) (and the papers cited therein). On the other hand, the LIML estimator often results in confidence intervals that are somewhat larger than those from the 2SLS estimator.

Moreover, using more instruments is not a solution, because the biases of instrumental-variables estimators increase with the number of instruments. See Hahn and Hausman (2003).

estat firststage produces several statistics for judging the explanatory power of the instruments and is most easily explained with examples.

> Example 3

Again building on the model fit in example 1 of \texttt{[R] ivregress}, we now explore the degree of correlation between the additional instruments \texttt{faminc}, \texttt{2.region}, \texttt{3.region}, and \texttt{4.region} and the endogenous regressor \texttt{hsngval}:

```
. use http://www.stata-press.com/data/r14/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
(output omitted)
. estat firststage
First-stage regression summary statistics
<table>
<thead>
<tr>
<th>Variable</th>
<th>Adjusted R-sq.</th>
<th>Partial R-sq.</th>
<th>F(4,44)</th>
<th>Prob &gt; F</th>
</tr>
</thead>
<tbody>
<tr>
<td>hsngval</td>
<td>0.6908</td>
<td>0.6557</td>
<td>13.2978</td>
<td>0.0000</td>
</tr>
</tbody>
</table>
```

Minimum eigenvalue statistic = 13.2978

<table>

</tbody>
</table>

To understand these results, recall that the first-stage regression is

\[
hsngval_i = \pi_0 + \pi_1 \text{pcturban}_i + \pi_2 \text{faminc} + \pi_3 \text{2.region} + \pi_4 \text{3.region} + \pi_5 \text{4.region} + \nu_i
\]
where \( v_i \) is an error term. The column marked “R-sq.” is the simple \( R^2 \) from fitting the first-stage regression by OLS, and the column marked “Adjusted R-sq.” is the adjusted \( R^2 \) from that regression. Higher values purportedly indicate stronger instruments, and instrumental-variables estimators exhibit less bias when the instruments are strongly correlated with the endogenous variable.

Looking at just the \( R^2 \) and adjusted \( R^2 \) can be misleading, however. If \( h\text{sn}g\text{val} \) were strongly correlated with the included exogenous variable \( \text{pcturban} \) but only weakly correlated with the additional instruments, then these statistics could be large even though a weak-instrument problem is present.

The partial \( R^2 \) statistic measures the correlation between \( h\text{sn}g\text{val} \) and the additional instruments after partialling out the effect of \( \text{pcturban} \). Unlike the \( R^2 \) and adjusted \( R^2 \) statistics, the partial \( R^2 \) statistic will not be inflated because of strong correlation between \( h\text{sn}g\text{val} \) and \( \text{pcturban} \). Bound, Jaeger, and Baker (1995) and others have promoted using this statistic.

The column marked “F(4, 44)” is an \( F \) statistic for the joint significance of \( \pi_2, \pi_3, \pi_4, \) and \( \pi_5 \), the coefficients on the additional instruments. Its \( p \)-value is listed in the column marked “Prob > F”. If the \( F \) statistic is not significant, then the additional instruments have no significant explanatory power for \( h\text{sn}g\text{val} \) after controlling for the effect of \( \text{pcturban} \). However, Hall, Rudebusch, and Wilcox (1996) used Monte Carlo simulation to show that simply having an \( F \) statistic that is significant at the typical 5% or 10% level is not sufficient. Stock, Wright, and Yogo (2002) suggest that the \( F \) statistic should exceed 10 for inference based on the 2SLS estimator to be reliable when there is one endogenous regressor.

`estat firststage` also presents the Cragg and Donald (1993) minimum eigenvalue statistic as a further test of weak instruments. Stock and Yogo (2005) discuss two characterizations of weak instruments: first, weak instruments cause instrumental-variables estimators to be biased; second, hypothesis tests of parameters estimated by instrumental-variables estimators may suffer from severe size distortions. The test statistic in our example is 13.30, which is identical to the \( F \) statistic just discussed because our model contains one endogenous regressor.

The null hypothesis of each of Stock and Yogo’s tests is that the set of instruments is weak. To perform these tests, we must first choose either the largest relative bias of the 2SLS estimator we are willing to tolerate or the largest rejection rate of a nominal 5% Wald test we are willing to tolerate. If the test statistic exceeds the critical value, we can conclude that our instruments are not weak.

The row marked “2SLS relative bias” contains critical values for the test that the instruments are weak based on the bias of the 2SLS estimator relative to the bias of the OLS estimator. For example, from past experience we might know that the OLS estimate of a parameter \( \beta \) may be 50% too high. Saying that we are willing to tolerate a 10\% relative bias means that we are willing to tolerate a bias of the 2SLS estimator no greater than 5\% (that is, 10\% of 50\%). In our rental rate model, if we are willing to tolerate a 10\% relative bias, then we can conclude that our instruments are not weak because the test statistic of 13.30 exceeds the critical value of 16.85. However, if we were willing to tolerate only a relative bias of 5\%, we would conclude that our instruments are weak because 13.30 < 16.85.

The rows marked “2SLS Size of nominal 5\% Wald test” and “LIML Size of nominal 5\% Wald test” contain critical values pertaining to Stock and Yogo’s (2005) second characterization of weak instruments. This characterization defines a set of instruments to be weak if a Wald test at the 5\% level can have an actual rejection rate of no more than 10\%, 15\%, 20\%, or 25\%. Using the current example, suppose that we are willing to accept a rejection rate of at most 10\%. Because 13.30 < 24.58, we cannot reject the null hypothesis of weak instruments. On the other hand, if we use the LIML estimator instead, then we can reject the null hypothesis because 13.30 > 5.44.
Technical note

Stock and Yogo (2005) tabulated critical values for 2SLS relative biases of 5%, 10%, 20%, and 30% for models with 1, 2, or 3 endogenous regressors and between 3 and 30 excluded exogenous variables (instruments). They also provide critical values for worst-case rejection rates of 5%, 10%, 20%, and 25% for nominal 5% Wald tests of the endogenous regressors with 1 or 2 endogenous regressors and between 1 and 30 instruments. If the model previously fit by `ivregress` has more instruments or endogenous regressors than these limits, the critical values are not shown. Stock and Yogo did not consider GMM estimators.

When the model being fit contains more than one endogenous regressor, the $R^2$ and $F$ statistics described above can overstate the relevance of the excluded instruments. Suppose that there are two endogenous regressors, $Y_1$ and $Y_2$, and that there are two additional instruments, $z_1$ and $z_2$. Say that $z_1$ is highly correlated with both $Y_1$ and $Y_2$ but $z_2$ is not correlated with either $Y_1$ or $Y_2$. Then the first-stage regression of $Y_1$ on $z_1$ and $z_2$ (along with the included exogenous variables) will produce large $R^2$ and $F$ statistics, as will the regression of $Y_2$ on $z_1$, $z_2$, and the included exogenous variables. Nevertheless, the lack of correlation between $z_2$ and $Y_1$ and $Y_2$ is problematic. Here, although the order condition indicates that the model is just identified (the number of excluded instruments equals the number of endogenous regressors), the irrelevance of $z_2$ implies that the model is in fact not identified. Even if the model is overidentified, including irrelevant instruments can adversely affect the properties of instrumental-variables estimators, because their biases increase as the number of instruments increases.

Example 4

`estat firststage` presents different statistics when the model contains multiple endogenous regressors. For illustration, we refit our model of rental rates, assuming that both `hsngval` and `faminc` are endogenously determined. We use `i.region` along with `popden`, a measure of population density, as additional instruments.
. ivregress 2sls rent pcturban (hsngval faminc = i.region popden)

Consider the endogenous regressor hsngval. Part of its variation is attributable to its correlation with the other regressors pcturban and faminc. The other component of hsngval’s variation is peculiar to it and orthogonal to the variation in the other regressors. Similarly, we can think of the instruments as predicting the variation in hsngval in two ways, one stemming from the fact that the predicted values of hsngval are correlated with the predicted values of the other regressors and one from the variation in the predicted values of hsngval that is orthogonal to the variation in the predicted values of the other regressors.

What really matters for instrumental-variables estimation is whether the component of hsngval that is orthogonal to the other regressors can be explained by the component of the predicted value of hsngval that is orthogonal to the predicted values of the other regressors in the model. Shea’s (1997) partial $R^2$ statistic measures this correlation. Because the bias of instrumental-variables estimators increases as more instruments are used, Shea’s adjusted partial $R^2$ statistic is often used instead, as it makes a degrees-of-freedom adjustment for the number of instruments, analogous to the adjusted $R^2$ measure used in OLS regression. Although what constitutes a “low” value for Shea’s partial $R^2$ depends on the specifics of the model being fit and the data used, these results, taken in isolation, do not strike us as being a particular cause for concern.

However, with this specification the minimum eigenvalue statistic is low. We cannot reject the null hypothesis of weak instruments for either of the characterizations we have discussed.

By default, estat firststage determines which statistics to present based on the number of endogenous regressors in the model previously fit. However, you can specify the all option to obtain all the statistics.

Technical note

If the previous estimation was conducted using aweights, pweights, or iweights, then the first-stage regression summary statistics are computed using those weights. However, in these cases the minimum eigenvalue statistic and its critical values are not available.
If the previous estimation included a robust VCE, then the first-stage $F$ statistic is based on a robust VCE as well; for example, if you fit your model with an HAC VCE using the Bartlett kernel and four lags, then the $F$ statistic reported is based on regression results using an HAC VCE using the Bartlett kernel and four lags. By default, the minimum eigenvalue statistic and its critical values are not displayed. You can use the `forcenonrobust` option to obtain them in these cases; the minimum eigenvalue statistic is computed using the weights, though the critical values reported may not be appropriate.

### estat overid

In addition to the requirement that instrumental variables be correlated with the endogenous regressors, the instruments must also be uncorrelated with the structural error term. If the model is overidentified, meaning that the number of additional instruments exceeds the number of endogenous regressors, then we can test whether the instruments are uncorrelated with the error term. If the model is just identified, then we cannot perform a test of overidentifying restrictions.

The estimator you used to fit the model determines which tests of overidentifying restrictions `estat overid` reports. If you used the 2SLS estimator without a robust VCE, `estat overid` reports Sargan’s (1958) and Basmann’s (1960) $\chi^2$ tests. If you used the 2SLS estimator and requested a robust VCE, Wooldridge’s robust score test of overidentifying restrictions is performed instead; without a robust VCE, Wooldridge’s test statistic is identical to Sargan’s test statistic. If you used the LIML estimator, `estat overid` reports the Anderson–Rubin (1950) likelihood-ratio test and Basmann’s (1960) $F$ test. `estat overid` reports Hansen’s (1982) $J$ statistic if you used the GMM estimator. Davidson and MacKinnon (1993, 235–236) give a particularly clear explanation of the intuition behind tests of overidentifying restrictions. Also see Judge et al. (1985, 614–616) for a summary of tests of overidentifying restrictions for the 2SLS and LIML estimators.

Tests of overidentifying restrictions actually test two different things simultaneously. One, as we have discussed, is whether the instruments are uncorrelated with the error term. The other is that the equation is misspecified and that one or more of the excluded exogenous variables should in fact be included in the structural equation. Thus a significant test statistic could represent either an invalid instrument or an incorrectly specified structural equation.

#### Example 5

Here we refit the model that treated just `hsngval` as endogenous using 2SLS, and then we perform tests of overidentifying restrictions:

```
. ivregress 2sls rent pcturban (hsngval = faminc i.region)  
(output omitted)
. estat overid
Tests of overidentifying restrictions:
Sargan (score) chi2(3) = 11.2877  (p = 0.0103)
Basmann chi2(3) = 12.8294  (p = 0.0050)
```

Both test statistics are significant at the 5% test level, which means that either one or more of our instruments are invalid or that our structural model is specified incorrectly.

One possibility is that the error term in our structural model is heteroskedastic. Both Sargan’s and Basmann’s tests assume that the errors are i.i.d.; if the errors are not i.i.d., then these tests are not valid. Here we refit the model by requesting heteroskedasticity-robust standard errors, and then we use `estat overid` to obtain Wooldridge’s score test of overidentifying restrictions, which is robust to heteroskedasticity.
. ivregress 2sls rent pcturban (hsngval = faminc i.region), vce(robust)
(output omitted)
. estat overid

Test of overidentifying restrictions:
Score chi²(3) = 6.8364 (p = 0.0773)

Here we no longer reject the null hypothesis that our instruments are valid at the 5% significance level, though we do reject the null at the 10% level. You can verify that the robust standard error on the coefficient for hsngval is more than twice as large as its nonrobust counterpart and that the robust standard error for pcturban is nearly 50% larger.

Technical note

The test statistic for the test of overidentifying restrictions performed after GMM estimation is simply the sample size times the value of the objective function $Q(\beta_1, \beta_2)$ defined in (5) of [R] ivregress, evaluated at the GMM parameter estimates. If the weighting matrix $W$ is optimal, meaning that $W = \text{Var}(z_i u_i)$, then $Q(\beta_1, \beta_2) \sim \chi^2(q)$, where $q$ is the number of overidentifying restrictions. However, if the estimated $W$ is not optimal, then the test statistic will not have an asymptotic $\chi^2$ distribution.

Like the Sargan and Basmann tests of overidentifying restrictions for the 2SLS estimator, the Anderson–Rubin and Basmann tests after LIML estimation are predicated on the errors’ being i.i.d. If the previous LIML results were reported with robust standard errors, then estat overid by default issues an error message and refuses to report the Anderson–Rubin and Basmann test statistics. You can use the forcenonrobust option to override this behavior. You can also use forcenonrobust to obtain the Sargan and Basmann test statistics after 2SLS estimation with robust standard errors.

By default, estat overid issues an error message if the previous estimation was conducted using aweights, pweights, or iweights. You can use the forceweights option to override this behavior, though the test statistics may no longer have the expected $\chi^2$ distributions.

Stored results

After 2SLS estimation, estat endogenous stores the following in r():

Scalars
r(durbin) Durbin $\chi^2$ statistic
r(p_durbin) $p$-value for Durbin $\chi^2$ statistic
r(wu) Wu–Hausman $F$ statistic
r(p_wu) $p$-value for Wu–Hausman $F$ statistic
r(df) degrees of freedom
r(wudf_r) denominator degrees of freedom for Wu–Hausman $F$
ri_score) robust score statistic
r(p_i_score) $p$-value for robust score statistic
r(hac_score) HAC score statistic
r(p_hac_score) $p$-value for HAC score statistic
r(lags) lags used in prewhitening
r(regF) regression-based $F$ statistic
r(p_regF) $p$-value for regression-based $F$ statistic
r(regFdf_n) regression-based $F$ numerator degrees of freedom
r(regFdf_r) regression-based $F$ denominator degrees of freedom
After GMM estimation, `estat endogenous` stores the following in `r()`:

Scalars
- $r(C)$: $C$ \(\chi^2\) statistic
- $r(p_C)$: \(p\)-value for $C$ \(\chi^2\) statistic
- $r(df)$: degrees of freedom

`estat firststage` stores the following in `r()`:

Scalars
- $r(mineig)$: minimum eigenvalue statistic

Matrices
- $r(mineigcv)$: critical values for minimum eigenvalue statistic
- $r(multiresults)$: Shea’s partial $R^2$ statistics
- $r(singleresults)$: first-stage $R^2$ and $F$ statistics

After 2SLS estimation, `estat overid` stores the following in `r()`:

Scalars
- $r(lags)$: lags used in prewhitening
- $r(df)$: \(\chi^2\) degrees of freedom
- $r(score)$: score \(\chi^2\) statistic
- $r(p_score)$: \(p\)-value for score \(\chi^2\) statistic
- $r(basmann)$: Basmann \(\chi^2\) statistic
- $r(p_basmann)$: \(p\)-value for Basmann \(\chi^2\) statistic
- $r(sargan)$: Sargan \(\chi^2\) statistic
- $r(p_sargan)$: \(p\)-value for Sargan \(\chi^2\) statistic

After LIML estimation, `estat overid` stores the following in `r()`:

Scalars
- $r(ar)$: Anderson–Rubin \(\chi^2\) statistic
- $r(p_ar)$: \(p\)-value for Anderson–Rubin \(\chi^2\) statistic
- $r(ar_df)$: \(\chi^2\) degrees of freedom
- $r(basmann)$: Basmann $F$ statistic
- $r(p_basmann)$: \(p\)-value for Basmann $F$ statistic
- $r(basmann_df_n)$: $F$ numerator degrees of freedom
- $r(basmann_df_d)$: $F$ denominator degrees of freedom

After GMM estimation, `estat overid` stores the following in `r()`:

Scalars
- $r(HansenJ)$: Hansen’s $J$ \(\chi^2\) statistic
- $r(p_HansenJ)$: \(p\)-value for Hansen’s $J$ \(\chi^2\) statistic
- $r(J_df)$: \(\chi^2\) degrees of freedom

Methods and formulas

Methods and formulas are presented under the following headings:

- `Notation`
- `estat endogenous`
- `estat firststage`
- `estat overid`
Recall from [R] `ivregress` that the model is

\[ y = Y\beta_1 + X_1\beta_2 + u = X\beta + u \]

\[ Y = X_1\Pi_1 + X_2\Pi_2 + V = Z\Pi + V \]

where \( y \) is an \( N \times 1 \) vector of the left-hand-side variable, \( N \) is the sample size, \( Y \) is an \( N \times p \) matrix of \( p \) endogenous regressors, \( X_1 \) is an \( N \times k_1 \) matrix of \( k_1 \) included exogenous regressors, \( X_2 \) is an \( N \times k_2 \) matrix of \( k_2 \) excluded exogenous variables, \( X = [Y \ X_1], \ Z = [X_1 \ X_2], \ u \) is an \( N \times 1 \) vector of errors, \( V \) is an \( N \times p \) matrix of errors, \( \beta = [\beta_1 \ \beta_2] \) is a \( k = (p + k_1) \times 1 \) vector of parameters, and \( \Pi \) is a \( (k_1 + k_2) \times p \) vector of parameters. If a constant term is included in the model, then one column of \( X_1 \) contains all ones.

**estat endogenous**

Partition \( Y \) as \( Y = [Y_1 \ Y_2] \), where \( Y_1 \) represents the \( p_1 \) endogenous regressors whose endogeneity is being tested and \( Y_2 \) represents the \( p_2 \) endogenous regressors whose endogeneity is not being tested. If the endogeneity of all endogenous regressors is being tested, \( Y = Y_1 \) and \( p_2 = 0 \). After GMM estimation, `estat endogenous` refits the model treating \( Y_1 \) as exogenous using the same type of weight matrix as requested at estimation time with the `wmatrix()` option; denote the Sargan statistic from this model by \( J_e \) and the estimated weight matrix by \( W_e \). Let \( S_e = W_e^{-1} \). `estat endogenous` removes from \( S_e \) the rows and columns corresponding to the variables represented by \( Y_1 \); denote the inverse of the resulting matrix by \( W'_e \). Next `estat endogenous` fits the model treating both \( Y_1 \) and \( Y_2 \) as endogenous, using the weight matrix \( W'_e \), denote the Sargan statistic from this model by \( J_c \). Then \( C = (J_c - J_e) \sim \chi^2(p_1) \). If one simply used the \( J \) statistic from the original model fit by `ivregress` in place of \( J_c \), then in finite samples \( J_c - J \) might be negative. The procedure used by `estat endogenous` is guaranteed to yield \( C \geq 0 \); see Hayashi (2000, 220).

Let \( \hat{u}_e \) denote the residuals from the model treating both \( Y_1 \) and \( Y_2 \) as endogenous, and let \( \hat{u}_c \) denote the residuals from the model treating only \( Y_2 \) as endogenous. Then Durbin’s (1954) statistic is

\[ D = \frac{\hat{u}'_e \Pi Y_1 \hat{u}_e - \hat{u}'_c \Pi Z \hat{u}_c}{\hat{u}'_c \hat{u}_c / N} \]

where \( \Pi Z = Z(Z'Z)^{-1}Z' \) and \( \Pi Y_1 = [Z \ Y_1][(Z \ Y_1)'(Z \ Y_1)]^{-1}(Z \ Y_1)' \) \( D \sim \chi^2(p_1) \). The Wu–Hausman (Wu 1974; Hausman 1978) statistic is

\[ WH = \frac{(\hat{u}'_e \Pi Y_1 \hat{u}_e - \hat{u}'_c \Pi Z \hat{u}_c)/p_1}{\{\hat{u}'_c \hat{u}_c - (\hat{u}'_e \Pi Y_1 \hat{u}_e - \hat{u}'_c \Pi Z \hat{u}_c)\} / (N - k_1 - p - 1)} \]

\( WH \sim F(p_1, N - k_1 - p - p_1) \). Baum, Schaffer, and Stillman (2003, 2007) discuss these tests in more detail.

Next we describe Wooldridge’s (1995) score test. The nonrobust version of Wooldridge’s test is identical to Durbin’s test. Suppose a robust covariance matrix was used at estimation time. Let \( \hat{\epsilon} \) denote the sample residuals obtained by fitting the model via OLS, treating \( Y \) as exogenous. We then regress each variable represented in \( Y \) on \( Z \); call the residuals for the \( j \)th regression \( \hat{r}_j, j = 1, \ldots, p \). Define \( \hat{k}_{ij} = \hat{\epsilon}_i \hat{r}_{ij}, i = 1, \ldots, N \). We then run the regression

\[ \mathbf{1} = \theta_1 \hat{k}_1 + \cdots + \theta_p \hat{k}_p + \epsilon \]
where 1 is an $N \times 1$ vector of ones and $\epsilon$ is a regression error term. $N - \text{RSS} \sim \chi^2(p)$, where RSS is the residual sum of squares from the regression just described. If instead an HAC VCE was used at estimation time, then before running the final regression we prewhiten the $\hat{K}_j$ series by using a VAR($q$) model, where $q$ is the number of lags specified with the lags() option.

The regression-based test proceeds as follows. Following Hausman (1978, 1259), we regress $Y$ on $Z$ and obtain the residuals $\hat{V}$. Next we fit the augmented regression

$$y = Y\beta_1 + X_1\beta_2 + \hat{V}\gamma + \epsilon$$

by OLS regression, where $\epsilon$ is a regression error term. A test of the exogeneity of $Y$ is equivalent to a test of $\gamma = 0$. As Cameron and Trivedi (2005, 276) suggest, this test can be made robust to heteroskedasticity, autocorrelation, or clustering by using the appropriate robust VCE when testing $\gamma = 0$. When a nonrobust VCE is used, this test is equivalent to the Wu–Hausman test described earlier. One cannot simply fit this augmented regression via 2SLS to test the endogeneity of a subset of the endogenous regressors; Davidson and MacKinnon (1993, 229–231) discuss a test of $\gamma = 0$ for the homoskedastic version of the augmented regression fit by 2SLS, but an appropriate robust test is not apparent.

**estat firststage**

When the structural equation includes one endogenous regressor, estat firststage fits the regression

$$Y = X_1\pi_1 + X_2\pi_2 + v$$

via OLS. The $R^2$ and adjusted $R^2$ from that regression are reported in the output, as well as the $F$ statistic from the Wald test of $H_0: \pi_2 = 0$. To obtain the partial $R^2$ statistic, estat firststage fits the regression

$$M_{X_1}y = M_{X_1}X_2\xi + \epsilon$$

by OLS, where $\epsilon$ is a regression error term, $\xi$ is a $k_2 \times 1$ parameter vector, and $M_{X_1} = I - X_1(X_1'X_1)^{-1}X_1'$; that is, the partial $R^2$ is the $R^2$ between $y$ and $X_2$ after eliminating the effects of $X_1$. If the model contains multiple endogenous regressors and the all option is specified, these statistics are calculated for each endogenous regressor in turn.

To calculate Shea’s partial $R^2$, let $y_1$ denote the endogenous regressor whose statistic is being calculated and $Y_0$ denote the other endogenous regressors. Define $\tilde{y}_1$ as the residuals obtained from regressing $y_1$ on $Y_0$ and $X_1$. Let $\hat{y}_1$ denote the fitted values obtained from regressing $y_1$ on $X_1$ and $X_2$; that is, $\hat{y}_1$ are the fitted values from the first-stage regression for $y_1$, and define the columns of $\tilde{Y}_0$ analogously. Finally, let $\tilde{y}_1$ denote the residuals from regressing $\hat{y}_1$ on $\tilde{Y}_0$ and $X_1$. Shea’s partial $R^2$ is the simple $R^2$ from the regression of $\tilde{y}_1$ on $\tilde{y}_1$; denote this as $R^2_s$. Shea’s adjusted partial $R^2$ is equal to $1 - (1 - R^2_s)(N - 1)/(N - k_Z + 1)$ if a constant term is included and $1 - (1 - R^2_s)(N - 1)/(N - k_Z)$ if there is no constant term included in the model, where $k_Z = k_1 + k_2$. For one endogenous regressor, one instrument, no exogenous regressors, and a constant term, $R^2_s$ equals the adjusted $R^2_s$.

The Stock and Yogo minimum eigenvalue statistic, first proposed by Cragg and Donald (1993) as a test for underidentification, is the minimum eigenvalue of the matrix

$$G = \frac{1}{k_Z} \tilde{\Sigma}^{-1/2} Y'M'X_1X_2(X_2'MX_1X_2)^{-1}X_2'MX_1Y\tilde{\Sigma}^{-1/2}$$
where
\[ \hat{\Sigma}_{VV} = \frac{1}{N - k_Z} Y' M_Z Y \]

\[ M_Z = I - Z(Z'Z)^{-1} Z', \] and \[ Z = [X_1 \ X_2]. \] Critical values are obtained from the tables in Stock and Yogo (2005).

estat overid

The Sargan (1958) and Basmann (1960) \( \chi^2 \) statistics are calculated by running the auxiliary regression
\[ \hat{u} = Z\delta + e \]
where \( \hat{u} \) are the sample residuals from the model and \( e \) is an error term. Then Sargan’s statistic is
\[ S = N \left( 1 - \frac{\hat{e}'\hat{e}}{\hat{u}'\hat{u}} \right) \]
where \( \hat{e} \) are the residuals from that auxiliary regression. Basmann’s statistic is calculated as
\[ B = S \frac{N - k_Z}{N - S} \]
Both \( S \) and \( B \) are distributed \( \chi^2(m) \), where \( m \), the number of overidentifying restrictions, is equal to \( k_Z - k \), where \( k \) is the number of endogenous regressors.

Wooldridge’s (1995) score test of overidentifying restrictions is identical to Sargan’s (1958) statistic under the assumption of i.i.d. and therefore is not recomputed unless a robust VCE was used at estimation time. If a heteroskedasticity-robust VCE was used, Wooldridge’s test proceeds as follows. Let \( \hat{Y} \) denote the \( N \times k \) matrix of fitted values obtained by regressing the endogenous regressors on \( X_1 \) and \( X_2 \). Let \( Q \) denote an \( N \times m \) matrix of excluded exogenous variables; the test statistic to be calculated is invariant to whichever \( m \) of the \( k_2 \) excluded exogenous variables is chosen. Define the \( i \)th element of \( \hat{k}_j, i = 1, \ldots, N, j = 1, \ldots, m \), as
\[ k_{ij} = \hat{q}_{ij}u_i \]
where \( \hat{q}_{ij} \) is the \( i \)th element of \( \hat{q}_j \), the fitted values from regressing the \( j \)th column of \( Q \) on \( \hat{Y} \) and \( X_1 \). Finally, fit the regression
\[ 1 = \theta_1\hat{k}_1 + \cdots + \theta_m\hat{k}_m + \epsilon \]
where \( 1 \) is an \( N \times 1 \) vector of ones and \( \epsilon \) is a regression error term, and calculate the residual sum of squares, RSS. Then the test statistic is \( W = N - \text{RSS} \). \( W \sim \chi^2(m) \). If an HAC VCE was used at estimation, then the \( \hat{k}_j \) are prewhitened using a \texttt{VAR}(p) model, where \( p \) is specified using the \texttt{lags()} option.

The Anderson–Rubin (1950), AR, test of overidentifying restrictions for use after the LIML estimator is calculated as \( AR = N(\kappa - 1) \), where \( \kappa \) is the minimal eigenvalue of a certain matrix defined in \texttt{ivregress}. AR \( \sim \chi^2(m) \). (Some texts define this statistic as \( N \ln(\kappa) \) because \( \ln(x) \approx (x - 1) \) for \( x \) near one.) Basmann’s \( F \) statistic for use after the LIML estimator is calculated as \( B_F = (\kappa - 1)(N - k_Z)/m \). \( B_F \sim F(m, N - k_Z) \).

Hansen’s \( J \) statistic is simply the sample size times the value of the GMM objective function defined in (5) of \texttt{ivregress}, evaluated at the estimated parameter values. Under the null hypothesis that the overidentifying restrictions are valid, \( J \sim \chi^2(m) \).

**ivtobit** — Tobit model with continuous endogenous covariates

**Description**

`ivtobit` fits tobit models where one or more of the covariates are endogenously determined. By default, `ivtobit` uses maximum likelihood estimation, but Newey’s (1987) minimum chi-squared (two-step) estimator can be requested. Both estimators assume that the endogenous covariates are continuous and so are not appropriate for use with discrete endogenous covariates.

**Quick start**

Tobit regression of \( y_1 \) on \( x \) and endogenous regressor \( y_2 \) that is instrumented by \( z \) where \( y_1 \) is left-censored at its observed minimum

ivtobit y1 x (y2 = z), ll

As above, but specify that \( y_1 \) is left-censored at 0 and right-censored at 20

ivtobit y1 x (y2 = z), ll(0) ul(20)

Use Newey’s two-step estimator

ivtobit y1 x (y2 = z), ll(0) ul(20) twostep

As above, and show first-stage regression results

ivtobit y1 x (y2 = z), ll(0) ul(20) twostep first

**Menu**

Statistics > Endogenous covariates > Tobit model with continuous endogenous covariates
**Syntax**

**Maximum likelihood estimator**

```
ivtobit depvar [varlist1] (varlist2 = varlist_iv) [if] [in] [weight],
   ll[(#)] ul[(#)] [mle_options]
```

**Two-step estimator**

```
ivtobit depvar [varlist1] (varlist2 = varlist_iv) [if] [in] [weight], twostep
   ll[(#)] ul[(#)] [tse_options]
```

varlist1 is the list of exogenous variables.

varlist2 is the list of endogenous variables.

varlist_iv is the list of exogenous variables used with varlist1 as instruments for varlist2.

*You must specify at least one of ll[(#)] and ul[(#)].*
ivtobit — Tobit model with continuous endogenous covariates

Model

- **twostep**: use Newey’s two-step estimator; the default is mle
- **ll(#)**: lower limit for left-censoring
- **ul(#)**: upper limit for right-censoring

SE

- vce(vcetype): vcetype may be twostep, bootstrap, or jackknife

Reporting

- level(#): set confidence level; default is level(95)
- first: report first-stage regression

display_options

control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

coeflegend

display legend instead of statistics

*twostep is required. You must specify at least one of ll(#) and ul(#).

- varlist1 and varlist1v may contain factor variables; see [U] 11.4.3 Factor variables.
- depvar, varlist1, varlist2, and varlist1v may contain time-series operators; see [U] 11.4.4 Time-series varlists.
- bootstrap, by, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands. fp is allowed with the maximum likelihood estimator.
- Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
- vce(), first, twostep, and weights are not allowed with the svy prefix; see [SVY] svy.
- fweights, iweights, and pweights are allowed with the maximum likelihood estimator. fweights are allowed with Newey’s two-step estimator. See [U] 11.1.6 weight.
- coeflegend does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

**Options for ML estimator**

- ll(#) and ul(#) indicate the lower and upper limits for censoring, respectively. You may specify one or both. Observations with \( \text{depvar} \leq \text{ll}() \) are left-censored; observations with \( \text{depvar} \geq \text{ul}() \) are right-censored; and remaining observations are not censored. You do not have to specify the censoring values at all. It is enough to type ll, ul, or both. When you do not specify a censoring value, ivtobit assumes that the lower limit is the minimum observed in the data (if ll is specified) and that the upper limit is the maximum (if ul is specified).

- mle requests that the conditional maximum-likelihood estimator be used. This is the default.

- constraints(constraints); see [R] estimation options.

- vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
Reporting level(#); see [R] estimation options.

first requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, first shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the tobit equation. The default is not to show these parameter estimates.

nocnsreport; see [R] estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] estimation options.

Maximization maximize_options: difficult, technique(algorithm_spec), iterate(#), [no] log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] maximize. This model’s likelihood function can be difficult to maximize, especially with multiple endogenous variables. The difficult and technique(bfgs) options may be helpful in achieving convergence.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following option is available with ivtobit but is not shown in the dialog box:

coeflegend; see [R] estimation options.

Options for two-step estimator

twostep is required and requests that Newey’s (1987) efficient two-step estimator be used to obtain the coefficient estimates.

ll(#) and ul(#) indicate the lower and upper limits for censoring, respectively. You may specify one or both. Observations with depvar ≤ ll() are left-censored; observations with depvar ≥ ul() are right-censored; and remaining observations are not censored. You do not have to specify the censoring values at all. It is enough to type ll, ul, or both. When you do not specify a censoring value, ivtobit assumes that the lower limit is the minimum observed in the data (if ll is specified) and that the upper limit is the maximum (if ul is specified).

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (twostep) and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

level(#) ; see [R] estimation options.

first requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, first shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the tobit equation. The default is not to show these parameter estimates.
The following option is available with `ivtobit` but is not shown in the dialog box:

```
coeflegend; see [R] estimation options.
```

### Remarks and examples

`ivtobit` fits models with censored dependent variables and endogenous covariates. You can use it to fit a tobit model when you suspect that one or more of the covariates is correlated with the error term. `ivtobit` is to tobit what `ivregress` is to linear regression analysis; see [R] `ivregress` for more information.

Formally, the model is

\[
\begin{align*}
y^*_1_i &= y_2_i \beta + x_1_i \gamma + u_i \\
y_2_i &= x_1_i \Pi_1 + x_2_i \Pi_2 + v_i
\end{align*}
\]

where \( i = 1, \ldots, N; y_2_i \) is a \( 1 \times p \) vector of endogenous variables; \( x_1_i \) is a \( 1 \times k_1 \) vector of exogenous variables; \( x_2_i \) is a \( 1 \times k_2 \) vector of additional instruments; and the equation for \( y_2_i \) is written in reduced form. By assumption \( (u_i, v_i) \sim N(0) \). \( \beta \) and \( \gamma \) are vectors of structural parameters, and \( \Pi_1 \) and \( \Pi_2 \) are matrices of reduced-form parameters. We do not observe \( y^*_1_i \); instead, we observe \( y_1_i \):

\[
y_1_i = \begin{cases} 
a & y^*_1_i < a \\
y^*_1_i & a \leq y^*_1_i \leq b \\
b & y^*_1_i > b
\end{cases}
\]

The order condition for identification of the structural parameters is that \( k_2 \geq p \). Presumably, \( \Sigma \) is not block diagonal between \( u_i \) and \( v_i \); otherwise, \( y_2_i \) would not be endogenous.

#### Technical note

This model is derived under the assumption that \( (u_i, v_i) \) is independent and identically distributed multivariate normal for all \( i \). The `vce(cluster clustvar)` option can be used to control for a lack of independence. As with the standard tobit model without endogeneity, if \( u_i \) is heteroskedastic, point estimates will be inconsistent.

#### Example 1

Using the same dataset as in [R] `ivprobit`, we now want to estimate women’s incomes. In our hypothetical world, all women who choose not to work receive $10,000 in welfare and child-support payments. Therefore, we never observe incomes under $10,000: a woman offered a job with an annual wage less than that would not accept and instead would collect the welfare payment. We model income as a function of the number of years of schooling completed, the number of children at home, and other household income. We again believe that `other_inc` is endogenous, so we use `male_edu` as an instrument.

Wald test of exogeneity (/alpha = 0):  chi2(1) = 4.44  Prob > chi2 = 0.0351

272 left-censored observations at fem_inc <= 10
228 uncensored observations
0 right-censored observations

Because we did not specify mle or twostep, ivtobit used the maximum likelihood estimator by default. ivtobit fits a tobit model, ignoring endogeneity, to get starting values for the full model. The header of the output contains the maximized log likelihood, the number of observations, and a Wald statistic and p-value for the test of the hypothesis that all the slope coefficients are jointly zero. At the end of the output, we see a count of the censored and uncensored observations.

Near the bottom of the output is a Wald test of the exogeneity of the instrumented variables. If the test statistic is not significant, there is not sufficient information in the sample to reject the null hypothesis of no endogeneity. Then the point estimates from ivtobit are consistent, although those from tobit are likely to have smaller standard errors.

Various two-step estimators have also been proposed for the endogenous tobit model, and Newey’s (1987) minimum chi-squared estimator is available with the twostep option.
Example 2

Refitting our labor-supply model with the two-step estimator yields

```
ivtobit fem_inc fem_educ kids (other_inc = male_educ), ll twostep
```

Two-step tobit with endogenous regressors

| Coef.  | Std. Err. | z      | P>|z|  | [95% Conf. Interval] |
|--------|-----------|--------|------|----------------------|
| other_inc | -0.9045397 | 0.1330015 | -6.80 | 0.000 | -1.165218 to -0.6438616 |
| fem_educ | 3.27239   | 0.3969399 | 8.24  | 0.000 | 2.494402 to 4.050378  |
| kids    | -3.312356 | 0.7220066 | -4.59 | 0.000 | -4.727463 to -1.897249 |
| _cons   | 19.24735  | 7.37392  | 2.61  | 0.009 | 4.794728 to 33.69997   |

Instrumented: other_inc
Instruments: fem_educ kids male_educ

Wald test of exogeneity: chi2(1) = 4.64          Prob > chi2 = 0.0312
272 left-censored observations at fem_inc <= 10
228 uncensored observations
0 right-censored observations

All the coefficients have the same signs as their counterparts in the maximum likelihood model. The Wald test at the bottom of the output confirms our earlier finding of endogeneity.

Technical note

In the tobit model with endogenous covariates, we assume that \((u_i, v_i)\) is multivariate normal with covariance matrix

\[
\text{Var}(u_i, v_i) = \Sigma = \\
\begin{bmatrix}
\sigma^2_u & \Sigma'_{21} \\
\Sigma_{21} & \Sigma_{22}
\end{bmatrix}
\]

Using the properties of the multivariate normal distribution, \(\text{Var}(u_i|v_i) \equiv \sigma^2_{u|v} = \sigma^2_u - \Sigma_{21}\Sigma^{-1}_{22}\Sigma_{21}\). Calculating the marginal effects on the conditional expected values of the observed and latent dependent variables and on the probability of censoring requires an estimate of \(\sigma^2_u\). The two-step estimator identifies only \(\sigma^2_{u|v}\), not \(\sigma^2_u\), so only the linear prediction and its standard error are available after you have used the `twostep` option. However, unlike the two-step probit estimator described in \([R]\) `ivprobit`, the two-step tobit estimator does identify \(\beta\) and \(\gamma\). See Wooldridge (2010, 683–684) for more information.

Methods and formulas

The estimation procedure used by `ivtobit` is similar to that used by `ivprobit`. For compactness, we write the model as

\[
\begin{align*}
y_{1i}^* &= z_i \delta + u_i \\
y_{2i} &= x_i \Pi + v_i
\end{align*}
\]

where \( z_i = (y_{2i}, x_{1i}) \), \( x_i = (x_{1i}, x_{2i}) \), \( \delta = (\beta', \gamma')' \), and \( \Pi = (\Pi_1', \Pi_2)' \). We do not observe \( y_{1i}^* \); instead, we observe

\[
y_{1i} = \begin{cases} 
  a & y_{1i}^* < a \\
  y_{1i}^* & a \leq y_{1i}^* \leq b \\
  b & y_{1i}^* > b
\end{cases}
\]

\((u_i, v_i)\) is distributed multivariate normal with mean zero and covariance matrix

\[
\Sigma = \begin{bmatrix} \sigma_u^2 & \Sigma' \\
\Sigma & \Sigma_22 \end{bmatrix}
\]

Using the properties of the multivariate normal distribution, we can write \( u_i = v'_i \alpha + \epsilon_i \), where \( \alpha = \Sigma^{-1}_2 \Sigma_21 \); \( \epsilon_i \sim N(0; \sigma^2_{u|v}) \), where \( \sigma^2_{u|v} = \sigma^2_u - \Sigma'_2 \Sigma^{-1}_2 \Sigma_21 \); and \( \epsilon_i \) is independent of \( v_i, z_i, \) and \( x_i \).

The likelihood function is straightforward to derive because we can write the joint density \( f(y_{1i}, y_{2i}|x_i) \) as \( f(y_{1i}|y_{2i}, x_i) f(y_{2i}|x_i) \). With one endogenous regressor,

\[
\ln f(y_{2i}|x_i) = -\frac{1}{2} \left\{ \ln2\pi + \ln\sigma^2_v + \frac{(y_{2i} - x_i \Pi)^2}{\sigma^2_v} \right\}
\]

and

\[
\ln f(y_{1i}|y_{2i}, x_i) = \begin{cases} 
  \ln \left\{ 1 - \Phi \left( \frac{m_i - a}{\sigma_{u|v}} \right) \right\} & y_{1i} = a \\
  -\frac{1}{2} \left\{ \ln2\pi + \ln\sigma^2_{u|v} + \frac{(y_{1i} - m_i)^2}{\sigma^2_{u|v}} \right\} & a < y_{1i} < b \\
  \ln \Phi \left( \frac{m_i - b}{\sigma_{u|v}} \right) & y_{1i} = b
\end{cases}
\]

where

\[
m_i = z_i \delta + \alpha (y_{2i} - x_i \Pi)
\]

and \( \Phi(\cdot) \) is the normal distribution function so that the log likelihood for observation \( i \) is

\[
\ln L_i = w_i \left\{ \ln f(y_{1i}|y_{2i}, x_i) + \ln f(y_{2i}|x_i) \right\}
\]

where \( w_i \) is the weight for observation \( i \) or one if no weights were specified. Instead of estimating \( \sigma_{u|v} \) and \( \sigma_v \) directly, we estimate \( \ln \sigma_{u|v} \) and \( \ln \sigma_v \).

For multiple endogenous covariates, we have

\[
\ln f(y_{2i}|x_i) = -\frac{1}{2} \left\{ p \ln2\pi + \ln |\Sigma_{22}| + v'_i \Sigma^{-1}_{22} v_i \right\}
\]

and \( \ln f(y_{1i}|y_{2i}, x_i) \) is the same as before, except that now

\[
m_i = z_i \delta + (y_{2i} - x_i \Pi) \Sigma^{-1}_{22} \Sigma_{21}
\]

Instead of maximizing the log-likelihood function with respect to \( \Sigma \), we maximize with respect to the Cholesky decomposition \( S \) of \( \Sigma \); that is, there exists a lower triangular matrix \( S \) such that \( SS' = \Sigma \). This maximization ensures that \( \Sigma \) is positive definite, as a covariance matrix must be. Let
\[ S = \begin{bmatrix}
  s_{11} & 0 & 0 & \ldots & 0 \\
  s_{21} & s_{22} & 0 & \ldots & 0 \\
  s_{31} & s_{32} & s_{33} & \ldots & 0 \\
  \vdots & \vdots & \vdots & \ddots & \vdots \\
  s_{p+1,1} & s_{p+1,2} & s_{p+1,3} & \ldots & s_{p+1,p+1}
\end{bmatrix} \]

With maximum likelihood estimation, this command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See \texttt{[P] _robust}, particularly \texttt{Maximum likelihood estimators} and \texttt{Methods and formulas}.

The maximum likelihood version of \texttt{ivtobit} also supports estimation with survey data. For details on VCEs with survey data, see \texttt{[SVY] variance estimation}.

The two-step estimates are obtained using Newey’s (1987) minimum chi-squared estimator. The procedure is identical to the one described in \texttt{[R] ivprobit}, except that \texttt{tobit} is used instead of \texttt{probit}.

### Acknowledgments

The two-step estimator is based on the \texttt{tobitiv} command written by Jonah Gelbach of the Department of Economics at Yale University and the \texttt{ivtobit} command written by Joe Harkness of the Institute of Policy Studies at Johns Hopkins University.

† `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.
predict

Description for predict

predict creates a new variable containing predictions such as linear predictions, standard errors, probabilities, and expected values.

Menu for predict

Statistics  >  Postestimation

Syntax for predict

After ML or twostep

    predict [type] newvar [if] [in] [ , statistic ]

After ML

    predict [type] { stub* | newvarlist } [if] [in] , scores

statistic      Description

Main
xb              linear prediction; the default
stdp            standard error of the linear prediction
stdf            standard error of the forecast; not available with two-step estimator
p(a,b)          Pr(a < yj < b) accounting for endogeneity; not available
                with two-step estimator
E(yj|a < yj < b) = E(yj|a < yj < b) accounting for endogeneity; not available
E(y_j^*)       yj = max{a, min(yj, b)} accounting for endogeneity; not available
                with two-step estimator

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for
the estimation sample.

stdf is not allowed with svy estimation results.

where a and b may be numbers or variables; a missing (a ≥ .) means −∞, and b missing (b ≥ .) means +∞; see [U] 12.2.1 Missing values.

Options for predict

xb, the default, calculates the linear prediction.

stdp calculates the standard error of the linear prediction. It can be thought of as the standard error
of the predicted expected value or mean for the observation’s covariate pattern. The standard error
of the prediction is also referred to as the standard error of the fitted value.
\texttt{stdf} calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by \texttt{stdf} are always larger than those produced by \texttt{stdp}; see Methods and formulas in \texttt{[R] regress postestimation}. \texttt{stdf} is not available with the two-step estimator.

\texttt{pr(a,b)} calculates $\Pr(a < x_jb + u_j < b)$, the probability that $y_j|x_j$ would be observed in the interval $(a, b)$ accounting for endogeneity.

$a$ and $b$ may be specified as numbers or variable names; $lb$ and $ub$ are variable names;

\texttt{pr(20,30)} calculates $\Pr(20 < x_jb + u_j < 30)$;

\texttt{pr(lb,ub)} calculates $\Pr(lb < x_jb + u_j < ub)$; and

\texttt{pr(20,ub)} calculates $\Pr(20 < x_jb + u_j < ub)$.

$a$ missing $(a \geq .)$ means $-\infty$; \texttt{pr(.,30)} calculates $\Pr(-\infty < x_jb + u_j < 30)$; and calculates $\Pr(lb < x_jb + u_j < 30)$ in observations for which $lb \geq .$

$b$ missing $(b \geq .)$ means $+\infty$; \texttt{pr(20.,)} calculates $\Pr(+\infty > x_jb + u_j > 20)$; and calculates $\Pr(20 < x_jb + u_j < ub)$ elsewhere.

\texttt{pr(a,b)} is not available with the two-step estimator.

\texttt{e(a,b)} calculates $E(x_jb + u_j \mid a < x_jb + u_j < b)$, the expected value of $y_j|x_j$ conditional on $y_j|x_j$ being in the interval $(a, b)$, meaning that $y_j|x_j$ is truncated. $a$ and $b$ are specified as they are for \texttt{pr(.)}. Endogeneity is accounted for when calculating \texttt{e(a,b)}. \texttt{e(a,b)} is not available with the two-step estimator.

\texttt{ystar(a,b)} calculates $E(y_j^*),$ where $y_j^* = a$ if $x_jb + u_j \leq a,$ $y_j^* = b$ if $x_jb + u_j \geq b,$ and $y_j^* = x_jb + u_j$ otherwise, meaning that $y_j^*$ is censored. $a$ and $b$ are specified as they are for \texttt{pr(.)}. Endogeneity is accounted for when calculating \texttt{ystar(a,b)}. \texttt{ystar(a,b)} is not available with the two-step estimator.

scores, not available with \texttt{twostep}, calculates equation-level score variables.

For models with one endogenous regressor, five new variables are created.

The first new variable will contain $\partial \ln L/\partial(z_i \delta)$.

The second new variable will contain $\partial \ln L/\partial(x_i \Pi)$.

The third new variable will contain $\partial \ln L/\partial \alpha$.

The fourth new variable will contain $\partial \ln L/\partial \ln \sigma_u | v$.

The fifth new variable will contain $\partial \ln L/\partial \ln \sigma_v$.

For models with $p$ endogenous regressors, $p + \{(p + 1)(p + 2)\}/2 + 1$ new variables are created.

The first new variable will contain $\partial \ln L/\partial(z_i \delta)$.

The second through $(p + 1)$th new score variables will contain $\partial \ln L/\partial(x_i \Pi_k), k = 1, \ldots, p$, where $\Pi_k$ is the $k$th column of $\Pi$.

The remaining score variables will contain the partial derivatives of $\ln L$ with respect to $s_{11}, s_{21}, \ldots, s_{p+1,1}, s_{22}, \ldots, s_{p+1,2}, \ldots, s_{p+1,p+1}$, where $s_{m,n}$ denotes the $(m, n)$ element of the Cholesky decomposition of the error covariance matrix.
margins

Description for margins

margins estimates margins of response for linear predictions, probabilities, and expected values.

Menu for margins

Statistics > Postestimation

Remarks and examples

Remarks are presented under the following headings:

Marginal effects
Obtaining predicted values

Marginal effects

Example 1

We can obtain average marginal effects by using the margins command after ivtobit. For the labor-supply model of example 1 in [R] ivtobit, suppose that we wanted to know the average marginal effects on the woman’s expected income, conditional on her income being greater than $10,000.
In our sample, increasing the number of children in the family by one decreases the expected wage by $1,304 on average (wages in our dataset are measured in thousands of dollars). male_edu has no effect because it appears only as an instrument.

Obtaining predicted values

After fitting your model using ivtobit, you can obtain the linear prediction and its standard error for both the estimation sample and other samples using the predict command. If you used the maximum likelihood estimator, you can also obtain conditional expected values of the observed and latent dependent variables, the standard error of the forecast, and the probability of observing the dependent variable in a specified interval. See [U] 20 Estimation and postestimation commands and [R] predict.

Methods and formulas

The linear prediction is calculated as \( z_i \hat{\delta} \), where \( \hat{\delta} \) is the estimated value of \( \delta \), and \( z_i \) and \( \delta \) are defined in (1a) of [R] ivtobit. Expected values and probabilities are calculated using the same formulas as those used by the standard tobit model. However, instead of evaluating the standard normal cumulative density and probability density at the linear prediction, expected values and probabilities are evaluated at \( m_i \), where \( m_i \) is defined in Methods and formulas of [R] ivtobit. Using \( m_i \) instead of \( z_i \hat{\delta} \) in the formulas accounts for endogeneity.

[U] 20 Estimation and postestimation commands
Description

`jackknife` performs jackknife estimation of the specified statistics (or expressions) for a Stata command or a user-written program. Statistics are jackknifed by estimating the command once for each observation or cluster in the dataset, leaving the associated observation or cluster out of the calculations. `jackknife` is designed for use with nonestimation commands, functions of coefficients, or user-written programs. To jackknife coefficients, we recommend using the `vce(jackknife)` option when allowed by the estimation command.

`jknife` is a synonym for `jackknife`.

Quick start

Jackknife estimate of the standard deviation of `v1` returned by `summarize` in `r(sd)`

```
jackknife sd=r(sd), rclass: summarize v1
```

Jackknife estimate of the statistic `r(mystat)` returned by `rclass` program `myprog1` that returns the sample size in `r(N)`

```
jackknife stat=r(mystat), rclass: myprog1 v1
```

As above, and save the results from each replication in `mydata.dta`

```
jackknife stat=r(mystat), rclass saving(mydata): myprog1 v1
```

Jackknife estimate of a difference in coefficients estimated by `regress`

```
jackknife diff=(_b[x2]-_b[x1]): regress y x1 x2 x3
```

Jackknife estimate of the statistic `e(mystat)` returned by `eclass` program `myprog2` that returns the sample size in `e(N)`

```
jackknife stat=e(mystat), eclass: myprog2 y x1 x2 x3
```

Jackknife estimates of coefficients stored in `e(b)` by `myprog2`

```
jackknife _b, eclass: myprog2 y x1 x2 x3
```

Add variables containing the pseudovalues of the coefficients to the dataset

```
jackknife _b, eclass keep: myprog2 y x1 x2 x3
```

`svy` is allowed; see [SVY] `svy jackknife`.  
`command` is any command that follows standard Stata syntax. All weight types supported by `command` are allowed except `aweights`; see [U] 11.1.6 weight.  
`coeflegend` does not appear in the dialog box.  
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
`exp_list` contains  
`name: elist`

`elist` contains  
`newvar = (exp)`

`eexp` is  
`specname`

`specname` is  
`_b`

`_b[]`

`_se`

`_se[]`

`eqno` is  
`##`

`name`

`exp` is a standard Stata expression; see [U] 13 Functions and expressions.
Distinguish between [], which are to be typed, and [], which indicate optional arguments.

**Options**

`eclass`, `rclass`, and `n(exp)` specify where `command` stores the number of observations on which it based the calculated results. We strongly advise you to specify one of these options.

`eclass` specifies that `command` store the number of observations in `e(N)`.

`rclass` specifies that `command` store the number of observations in `r(N)`.

`n(exp)` specifies an expression that evaluates to the number of observations used. Specifying `n(r(N))` is equivalent to specifying the `rclass` option. Specifying `n(e(N))` is equivalent to specifying the `eclass` option. If `command` stores the number of observations in `r(N1)`, specify `n(r(N1))`.

If you specify no options, `jackknife` will assume `eclass` or `rclass`, depending on which of `e(N)` and `r(N)` is not missing (in that order). If both `e(N)` and `r(N)` are missing, `jackknife` assumes that all observations in the dataset contribute to the calculated result. If that assumption is incorrect, the reported standard errors will be incorrect. For instance, say that you specify

```
.jackknife coef=_b[x2]: myreg y x1 x2 x3
```

where `myreg` uses `e(n)` instead of `e(N)` to identify the number of observations used in calculations. Further assume that observation 42 in the dataset has `x3` equal to missing. The 42nd observation plays no role in obtaining the estimates, but `jackknife` has no way of knowing that and will use the wrong `N`. If, on the other hand, you specify

```
.jackknife coef=_b[x2], n(e(n)): myreg y x1 x2 x3
```

`jackknife` will notice that observation 42 plays no role. The `n(e(n))` option is specified because `myreg` is an estimation command but it stores the number of observations used in `e(n)` (instead of the standard `e(N)`). When `jackknife` runs the regression omitting the 42nd observation, `jackknife` will observe that `e(n)` has the same value as when `jackknife` previously ran the regression using all the observations. Thus `jackknife` will know that `myreg` did not use the observation.
Options

\texttt{cluster(varlist)} specifies the variables identifying sample clusters. If \texttt{cluster()} is specified, one cluster is left out of each call to \texttt{command}, instead of 1 observation.

\texttt{idcluster(newvar)} creates a new variable containing a unique integer identifier for each resampled cluster, starting at 1 and leading up to the number of clusters. This option may be specified only when the \texttt{cluster()} option is specified. \texttt{idcluster()} helps identify the cluster to which a pseudovalue belongs.

\texttt{saving(filename[, suboptions])} creates a Stata data file (\texttt{.dta} file) consisting of (for each statistic in \texttt{exp_list}) a variable containing the replicates.

\texttt{double} specifies that the results for each replication be saved as doubles, meaning 8-byte reals. By default, they are saved as floats, meaning 4-byte reals. This option may be used without the \texttt{saving()} option to compute the variance estimates by using double precision.

\texttt{every(#)} specifies that results be written to disk every \#th replication. \texttt{every()} should be specified only in conjunction with \texttt{saving()} when \texttt{command} takes a long time for each replication. This option will allow recovery of partial results should some other software crash your computer. See \texttt{[P] postfile}.

\texttt{replace} specifies that \texttt{filename} be overwritten if it exists. This option does not appear in the dialog box.

\texttt{keep} specifies that new variables be added to the dataset containing the pseudovalue statistics. For instance, if you typed

\begin{verbatim}
. jackknife coef=_b[x2], eclass keep: regress y x1 x2 x3
\end{verbatim}

new variable \texttt{coef} would be added to the dataset containing the pseudovalue statistics for \texttt{_b[x2]}. Let \(b\) be the value of \texttt{_b[x2]} when all observations are used to fit the model, and let \(b(j)\) be the value when the \(j\)th observation is omitted. The pseudovalue statistics defined as

\[
pseudovalue_j = N \{b - b(j)\} + b(j)
\]

where \(N\) is the number of observations used to produce \(b\).

When the \texttt{cluster()} option is specified, each cluster is given at most one nonmissing pseudovalue. The \texttt{keep} option implies the \texttt{nodrop} option.

\texttt{mse} specifies that \texttt{jackknife} compute the variance by using deviations of the replicates from the observed value of the statistics based on the entire dataset. By default, \texttt{jackknife} computes the variance by using deviations of the pseudovalue statistics from their mean.

Reporting

\texttt{level(#)}; see \texttt{[R] estimation options}.

\texttt{notable} suppresses the display of the table of results.

\texttt{noheader} suppresses the display of the table header. This option implies \texttt{nolegend}.

\texttt{nolegend} suppresses the display of the table legend. The table legend identifies the rows of the table with the expressions they represent.

\texttt{verbose} specifies that the full table legend be displayed. By default, coefficients and standard errors are not displayed.

\texttt{nodots} suppresses display of the replication dots. By default, one dot character is displayed for each successful replication. A red ‘x’ is displayed if \texttt{command} returns an error or if one of the values in \texttt{exp_list} is missing.
noisily specifies that any output from *command* be displayed. This option implies the nodots option.

*trace* causes a trace of the execution of *command* to be displayed. This option implies the noisily option.

*title(text)* specifies a title to be displayed above the table of jackknife results; the default title is `Jackknife results` or what is produced in `e(title)` by an estimation command.

display_options: noic, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fswrap(#), fswrapon(style), cfomat(%, fmt), pformat(%, fmt), sformat(%, fmt), and nolstretch; see [R] estimation options.

eform_option causes the coefficient table to be displayed in exponentiated form; see [R] eform_option.

*command* determines which *eform* option is allowed (*eform(string)* and *eform* are always allowed).

*command* determines which of the following are allowed (*eform(string)* and *eform* are always allowed):

<table>
<thead>
<tr>
<th>eform_option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>eform(string)</em></td>
<td>use <em>string</em> for the column title</td>
</tr>
<tr>
<td><em>eform</em></td>
<td>exponentiated coefficient, <em>string</em> is exp(b)</td>
</tr>
<tr>
<td><em>hr</em></td>
<td>hazard ratio, <em>string</em> is Haz. Ratio</td>
</tr>
<tr>
<td><em>shr</em></td>
<td>subhazard ratio, <em>string</em> is SHR</td>
</tr>
<tr>
<td><em>irr</em></td>
<td>incidence-rate ratio, <em>string</em> is IRR</td>
</tr>
<tr>
<td><em>or</em></td>
<td>odds ratio, <em>string</em> is Odds Ratio</td>
</tr>
<tr>
<td><em>rrr</em></td>
<td>relative-risk ratio, <em>string</em> is RRR</td>
</tr>
</tbody>
</table>

Advanced

*nodrop* prevents observations outside *e(sample)* and the if and in qualifiers from being dropped before the data are resampled.

*reject(exp)* identifies an expression that indicates when results should be rejected. When *exp* is true, the resulting values are reset to missing values.

The following option is available with *jackknife* but is not shown in the dialog box:

*coeflegend*; see [R] estimation options.

**Remarks and examples**

Remarks are presented under the following headings:

- **Introduction**
- **Using jackknife**
- **Jackknifed standard deviation**
- **Collecting multiple statistics**
- **Collecting coefficients**
Introduction

Although the jackknife—developed in the late 1940s and early 1950s—is of largely historical interest today, it is still useful in searching for overly influential observations. This feature is often forgotten. In any case, the jackknife is

- an alternative, first-order unbiased estimator for a statistic;
- a data-dependent way to calculate the standard error of the statistic and to obtain significance levels and confidence intervals; and
- a way of producing measures called pseudovalues for each observation, reflecting the observation’s influence on the overall statistic.

The idea behind the simplest form of the jackknife—the one implemented here—is to repeatedly calculate the statistic in question, each time omitting just one of the dataset’s observations. Assume that our statistic of interest is the sample mean. Let $y_j$ be the $j$th observation of our data on some measurement $y$, where $j = 1, \ldots, N$ and $N$ is the sample size. If $\bar{y}$ is the sample mean of $y$ using the entire dataset and $\bar{y}(j)$ is the mean when the $j$th observation is omitted, then

$$\bar{y} = \frac{(N - 1) \bar{y}(j) + y_j}{N}$$

Solving for $y_j$, we obtain

$$y_j = N \bar{y} - (N - 1) \bar{y}(j)$$

These are the pseudovalues that \texttt{jackknife} calculates. To move this discussion beyond the sample mean, let $\hat{\theta}$ be the value of our statistic (not necessarily the sample mean) using the entire dataset, and let $\hat{\theta}(j)$ be the computed value of our statistic with the $j$th observation omitted. The pseudovalue for the $j$th observation is

$$\hat{\theta}^*_j = N \hat{\theta} - (N - 1) \hat{\theta}(j)$$

The mean of the pseudovalues is the alternative, first-order unbiased estimator mentioned above, and the standard error of the mean of the pseudovalues is an estimator for the standard error of $\hat{\theta}$ (Tukey 1958).

The jackknife estimate of variance has been largely replaced by the bootstrap estimate (see \texttt{bootstrap}), which is widely viewed as more efficient and robust. The use of jackknife pseudovalues to detect outliers is too often forgotten and is something the bootstrap does not provide. See Mosteller and Tukey (1977, 133–163) and Mooney and Duval (1993, 22–27) for more information.

Using \texttt{jackknife}

Typing

```
. jackknife exp_list: command
```

executes \texttt{command} once for each observation in the dataset, leaving the associated observation out of the calculations that make up \texttt{exp_list}.

\texttt{command} defines the statistical command to be executed. Most Stata commands and user-written programs can be used with \texttt{jackknife}, as long as they follow standard Stata syntax and allow the \texttt{if} qualifier; see [U] 11 Language syntax. The by prefix may not be part of \texttt{command}.

\texttt{exp_list} specifies the statistics to be collected from the execution of \texttt{command}. If \texttt{command} changes the contents in \texttt{e(b)}, \texttt{exp_list} is optional and defaults to \_b.
When the `cluster()` option is given, clusters are omitted instead of observations, and \( N \) is the number of clusters instead of the sample size.

### Example 1

As our first example, we will show that the jackknife standard error of the sample mean is equivalent to the standard error of the sample mean computed using the classical formula in the `ci means` command. We use the `double` option to compute the standard errors with the same precision as the `ci means` command.

```stata
. use http://www.stata-press.com/data/r14/auto
   (1978 Automobile Data)
. jackknife r(mean), double: summarize mpg
   (running summarize on estimation sample)
Jackknife replications (74)
1 2 3 4 5 .................................................. 50
.................................................. 50
........................
Jackknife results Number of obs = 74
Replications = 74
command:  summarize mpg
   _jk_1:  r(mean)
   n():  r(N)

<table>
<thead>
<tr>
<th></th>
<th>Jackknife</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Coef.</td>
<td>Std. Err.</td>
<td>t</td>
<td>P&gt;</td>
</tr>
<tr>
<td>_jk_1</td>
<td>21.2973</td>
<td>.6725511</td>
<td>31.67</td>
<td>0.000</td>
</tr>
</tbody>
</table>

. ci means mpg
Variable |     Obs |   Mean | Std. Err. | [95% Conf. Interval]
mpg      |       74 | 21.2973 | .6725511 | 19.9569  | 22.63769 |
```

**Jackknifed standard deviation**

### Example 2

`Mosteller and Tukey (1977, 139–140)` request a 95% confidence interval for the standard deviation of the 11 values:

0.1, 0.1, 0.1, 0.4, 0.5, 1.0, 1.1, 1.3, 1.9, 1.9, 4.7

Stata’s `summarize` command calculates the mean and standard deviation and stores them as `r(mean)` and `r(sd)`. To obtain the jackknifed standard deviation of the 11 values and save the pseudovalues as a new variable, `sd`, we would type

```stata
```
. clear
. input x
 x
1. 0.1
2. 0.1
3. 0.1
4. 0.4
5. 0.5
6. 1.0
7. 1.1
8. 1.3
9. 1.9
10. 1.9
11. 4.7
12. end
. jackknife sd=r(sd), rclass keep: summarize x
  (running summarize on estimation sample)
  Jackknife replications (11)
  1 |  2 |  3 |  4 |  5

  Jackknife results Number of obs = 11
  Replications = 11
  command:  summarize x
  sd:  r(sd)
  n():  r(N)

|                | Jackknife Coef. | Std. Err. | t     | P>|t|    | [95% Conf. Interval] |
|----------------|-----------------|-----------|-------|--------|---------------------|
| sd             | 1.343469        | .624405   | 2.15  | 0.057  | -.047792 to 2.73473 |

Interpreting the output, the standard deviation reported by `summarize mpg` is 1.34. The jackknife standard error is 0.62. The 95% confidence interval for the standard deviation is $-0.048$ to $2.73$.

By specifying `keep`, `jackknife` creates in our dataset a new variable, `sd`, for the pseudovalues.

. list, sep(4)

<table>
<thead>
<tr>
<th>x</th>
<th>sd</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>.1 1.139977</td>
</tr>
<tr>
<td>2.</td>
<td>.1 1.139977</td>
</tr>
<tr>
<td>3.</td>
<td>.1 1.139977</td>
</tr>
<tr>
<td>4.</td>
<td>.4  .8893147</td>
</tr>
<tr>
<td>5.</td>
<td>.5  .824267</td>
</tr>
<tr>
<td>6.</td>
<td>1   .632489</td>
</tr>
<tr>
<td>7.</td>
<td>1.1 .6203189</td>
</tr>
<tr>
<td>8.</td>
<td>1.3 .6218889</td>
</tr>
<tr>
<td>9.</td>
<td>1.9 .835419</td>
</tr>
<tr>
<td>10.</td>
<td>1.9 .835419</td>
</tr>
<tr>
<td>11.</td>
<td>4.7 7.703949</td>
</tr>
</tbody>
</table>

The jackknife estimate is the average of the `sd` variable, so `sd` contains the individual values of our statistic. We can see that the last observation is substantially larger than the others. The last observation is certainly an outlier, but whether that reflects the considerable information it contains or indicates that it should be excluded from analysis depends on the context of the problem. Here Mosteller
and Tukey created the dataset by sampling from an exponential distribution, so the observation is informative.

Example 3

Let's repeat the example above using the automobile dataset, obtaining the standard error of the standard deviation of mpg.

```
use http://www.stata-press.com/data/r14/auto, clear
(1978 Automobile Data)
.jackknife sd=r(sd), rclass keep: summarize mpg
(running summarize on estimation sample)
Jackknife replications (74)

Jackknife results Number of obs = 74
command: summarize mpg
sd: r(sd)
n(): r(N)

----------------------------------------------
              | Jackknife
Coef. Std. Err.  t    P>|t|    [95% Conf. Interval]
----------------------------------------------
   sd | 5.785503  .6072509  9.53  0.000   4.575254   6.995753

Let's look at sd more carefully:

.summarize sd, detail

Pseudovalues: r(sd)
Percentiles Smallest
 1%  2.870471  2.870471
 5%  2.870471  2.870471
10%  2.906255  2.870471  Obs        74
25%  3.328489  2.870471  Sum of Wgt. 74
50%  3.948335                      Mean       5.817374
     Largest Std. Dev.             5.223777
    75%  6.844441  17.34316
    90%  9.597018  19.7617  Variance 27.28777
    95% 17.34316   19.7617  Skewness  4.07202
   99% 38.60905   38.60905  Kurtosis 23.37823

.list make mpg sd if sd > 30

<table>
<thead>
<tr>
<th>make</th>
<th>mpg</th>
<th>sd</th>
</tr>
</thead>
<tbody>
<tr>
<td>71.</td>
<td>VW Diesel</td>
<td>38.60905</td>
</tr>
</tbody>
</table>
```

Here the VW Diesel is the only diesel car in our dataset.
Collecting multiple statistics

Example 4

jackknife is not limited to collecting just one statistic. For instance, we can use summarize, detail and then obtain the jackknife estimate of the standard deviation and skewness. summarize, detail stores the standard deviation in r(sd) and the skewness in r(skewness), so we might type

```
. use http://www.stata-press.com/data/r14/auto, clear
   (1978 Automobile Data)
. jackknife sd=r(sd) skew=r(skewness), rclass: summarize mpg, detail
   (running summarize on estimation sample)
Jackknife replications (74)
     1     2     3     4     5
..........................
50
Jackknife results

command:  summarize mpg, detail
  sd:  r(sd)
  skew:  r(skewness)
  n():  r(N)

|             | Coef. | Std. Err. | t    | P>|t|  | [95% Conf. Interval] |
|-------------|-------|-----------|------|------|---------------------|
| sd          | 5.785503 | .6072509  | 9.53 | 0.000 | 4.575254  6.995753  |
| skew        | .9487176  | .3367242  | 2.82 | 0.006 | .2776272 1.619808  |
```

Collecting coefficients

Example 5

jackknife can also collect coefficients from estimation commands. For instance, using auto.dta, we might wish to obtain the jackknife standard errors of the coefficients from a regression in which we model the mileage of a car by its weight and trunk space. To do this, we could refer to the coefficients as \_b[weight], \_b[trunk], \_se[weight], and \_se[trunk] in the exp_list, or we could simply use the extended expressions \_b. In fact, jackknife assumes \_b by default when used with estimation commands.
. use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
. jackknife: regress mpg weight trunk
(running regress on estimation sample)
Jackknife replications (74)
1 2 3 4 5
...........................
50

Linear regression
Number of obs = 74
Replications = 74
F( 2, 73) = 78.10
Prob > F = 0.0000
R-squared = 0.6543
Adj R-squared = 0.6446
Root MSE = 3.4492

|           | Coef. | Std. Err. | t     | P>|t|   | [95% Conf. Interval] |
|-----------|-------|-----------|-------|-------|---------------------|
|mpg        |       |           |       |       |                     |

John Wilder Tukey (1915–2000) was born in Massachusetts. He studied chemistry at Brown and mathematics at Princeton and afterward worked at both Princeton and Bell Labs, as well as being involved in a great many government projects, consultancies, and committees. He made outstanding contributions to several areas of statistics, including time series, multiple comparisons, robust statistics, and exploratory data analysis. Tukey was extraordinarily energetic and inventive, not least in his use of terminology: he is credited with inventing the terms bit and software, in addition to ANOVA, boxplot, data analysis, hat matrix, jackknife, stem-and-leaf plot, trimming, and winsorizing, among many others. Tukey’s direct and indirect impacts mark him as one of the greatest statisticians of all time.
**Stored results**

`jackknife` stores the following in `e()`:

**Scalars**
- `e(N)` : sample size
- `e(N_reps)` : number of complete replications
- `e(N_misreps)` : number of incomplete replications
- `e(N_clust)` : number of clusters
- `e(k_eq)` : number of equations in `e(b)`
- `e(k_extra)` : number of extra equations
- `e(k_exp)` : number of expressions
- `e(k_eexp)` : number of extended expressions (_b or _se)
- `e(df_r)` : degrees of freedom

**Macros**
- `e(cmdname)` : command name from `command`
- `e(cmd)` : same as `e(cmdname)` or `jackknife`
- `e(command)` : `command`
- `e(cmdline)` : command as typed
- `e(prefix)` : `jackknife`
- `e(wtype)` : weight type
- `e(wexp)` : weight expression
- `e(title)` : title in estimation output
- `e(cluster)` : cluster variables
- `e(pseudo)` : new variables containing pseudovalues
- `e(nfunction)` : `e(N), r(N), n()` option, or empty
- `e(exp#)` : expression for the #th statistic
- `e(mse)` : from `mse` option
- `e(vce)` : `jackknife`
- `e(vcetype)` : title used to label Std. Err.
- `e(properties)` : `b V`

**Matrices**
- `e(b)` : observed statistics
- `e(b_jk)` : jackknife estimates
- `e(V)` : jackknife variance–covariance matrix
- `e(V_modelbased)` : model-based variance

When `exp_list` is `_b`, `jackknife` will also carry forward most of the results already in `e()` from `command`.

**Methods and formulas**

Let \( \hat{\theta} \) be the observed value of the statistic, that is, the value of the statistic calculated using the original dataset. Let \( \hat{\theta}_{(j)} \) be the value of the statistic computed by leaving out the \( j \)th observation (or cluster); thus \( j = 1, 2, \ldots, N \) identifies an individual observation (or cluster), and \( N \) is the total number of observations (or clusters). The \( j \)th pseudovalue is given by

\[
\hat{\theta}_j^* = \hat{\theta}_{(j)} + N\{\hat{\theta} - \hat{\theta}_{(j)}\}
\]

When the `mse` option is specified, the standard error is estimated as

\[
\hat{se} = \left\{ \frac{N - 1}{N} \sum_{j=1}^N (\hat{\theta}_{(j)} - \hat{\theta})^2 \right\}^{1/2}
\]
and the jackknife estimate is

\[
\bar{\theta} = \frac{1}{N} \sum_{j=1}^{N} \hat{\theta}(j)
\]

Otherwise, the standard error is estimated as

\[
\hat{se} = \left\{ \frac{1}{N(N-1)} \sum_{j=1}^{N} (\hat{\theta}_j^* - \bar{\theta}^*)^2 \right\}^{1/2}
\]

where \( \bar{\theta}^* \) is the jackknife estimate. The variance–covariance matrix is similarly computed.

<tr>
<td><code>pwcompare</code></td>
<td>pairwise comparisons of estimates</td>
</tr>
<tr>
<td><code>test</code></td>
<td>Wald tests of simple and composite linear hypotheses</td>
</tr>
<tr>
<td><code>testnl</code></td>
<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

The postestimation command is allowed only if it may be used after `command`. 
predict

The syntax of predict (and whether predict is even allowed) following jackknife depends on the command used with jackknife.

margins

The syntax of margins (and whether margins is even allowed) following jackknife depends on the command used with jackknife.

[R] jackknife — Jackknife estimation
[U] 20 Estimation and postestimation commands
**kappa — Interrater agreement**

**Description**

`kap` and `kappa` calculate the kappa-statistic measure of interrater agreement. `kap` calculates the statistic for two unique raters or at least two nonunique raters. `kappa` calculates only the statistic for nonunique raters, but it handles the case where data have been recorded as rating frequencies. `kapwgt` defines weights used by `kap` in measuring the importance of disagreements.

**Quick start**

Calculate interrater agreement for values `rater1` and `rater2`

```
kap rater1 rater2
```

Add table of assessments

```
kap rater1 rater2, tab
```

As above, and apply frequency weights defined by `wvar`

```
kap rater1 rater2 [fweight=wvar], tab
```

Agreement for values from three nonunique raters stored in `rater1`, `rater2`, and `rater3`

```
kap rater1 rater2 rater3
```

Add values from an additional three raters stored in `rater4`, `rater5`, and `rater6`

```
kap rater1-rater6
```

Use weights \(1 - \frac{|i - j|}{(k - 1)}\) to weight disagreements between rater 1 and rater 2

```
kap rater1 rater2, wgt(w)
```

Number of times each subject classified in categories stored in `poor`, `fair`, and `good`

```
kappa poor fair good
```
Menu

**kap: two unique raters**
Statistics > Epidemiology and related > Other > Interrater agreement, two unique raters

**kapwgt**
Statistics > Epidemiology and related > Other > Define weights for the above (kap)

**kap: nonunique raters**
Statistics > Epidemiology and related > Other > Interrater agreement, nonunique raters

**kappa**
Statistics > Epidemiology and related > Other > Interrater agreement, nonunique raters with frequencies

Syntax

**Interrater agreement, two unique raters**

```

```

**Weights for weighting disagreements**

```
kapwgt wgtid [ 1 \# 1 \#\# 1 . . ]
```

**Interrater agreement, nonunique raters, variables record ratings for each rater**

```
kap varname1 varname2 varname3 [ . . . ] [if] [in] [weight]
```

**Interrater agreement, nonunique raters, variables record frequency of ratings**

```
kappa varlist [if] [in]
```

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tab</strong></td>
<td>display table of assessments</td>
</tr>
<tr>
<td><strong>wgt(wgtid)</strong></td>
<td>specify how to weight disagreements; see Options for alternatives</td>
</tr>
<tr>
<td><strong>absolute</strong></td>
<td>treat rating categories as absolute</td>
</tr>
</tbody>
</table>

fweights are allowed; see [U] 11.1.6 weight.
Options

tab displays a tabulation of the assessments by the two raters.

\texttt{wgt(wgtid)} specifies that \texttt{wgtid} be used to weight disagreements. You can define your own weights by using \texttt{kapwgt}; \texttt{wgt()} then specifies the name of the user-defined matrix. For instance, you might define

\begin{verbatim}
\texttt{. kapwgt mine 1 \ 0.8 1 \ 0.8 1 \ 0 0 .8 1}
\end{verbatim}

and then

\begin{verbatim}
\texttt{. kap rata ratb, wgt(mine)}
\end{verbatim}

Also, two prerecorded weights are available.

\texttt{wgt(w)} specifies weights $1 - |i - j|/(k - 1)$, where $i$ and $j$ index the rows and columns of the ratings by the two raters and $k$ is the maximum number of possible ratings.

\texttt{wgt(w2)} specifies weights $1 - \left(\frac{i - j}{k - 1}\right)^2$.

\texttt{absolute} is relevant only if \texttt{wgt()} is also specified. The \texttt{absolute} option modifies how $i$, $j$, and $k$ are defined and how corresponding entries are found in a user-defined weighting matrix. When \texttt{absolute} is not specified, $i$ and $j$ refer to the row and column index, not to the ratings themselves. Say that the ratings are recorded as $\{0, 1, 1.5, 2\}$. There are four ratings; $k = 4$, and $i$ and $j$ are still 1, 2, 3, and 4 in the formulas above. Index 3, for instance, corresponds to rating $= 1.5$. This system is convenient but can, with some data, lead to difficulties.

When \texttt{absolute} is specified, all ratings must be integers, and they must be coded from the set $\{1, 2, 3, \ldots\}$. Not all values need be used; integer values that do not occur are simply assumed to be unobserved.

Remarks and examples

Remarks are presented under the following headings:

- \textit{Two raters}
- \textit{More than two raters}

The kappa-statistic measure of agreement is scaled to be 0 when the amount of agreement is what would be expected to be observed by chance and 1 when there is perfect agreement. For intermediate values, Landis and Koch (1977a, 165) suggest the following interpretations:

<table>
<thead>
<tr>
<th>Value</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>below 0.0</td>
<td>Poor</td>
</tr>
<tr>
<td>0.00–0.20</td>
<td>Slight</td>
</tr>
<tr>
<td>0.21–0.40</td>
<td>Fair</td>
</tr>
<tr>
<td>0.41–0.60</td>
<td>Moderate</td>
</tr>
<tr>
<td>0.61–0.80</td>
<td>Substantial</td>
</tr>
<tr>
<td>0.81–1.00</td>
<td>Almost perfect</td>
</tr>
</tbody>
</table>
Two raters

Example 1

Consider the classification by two radiologists of 85 xeromammograms as normal, benign disease, suspicion of cancer, or cancer (a subset of the data from Boyd et al. [1982] and discussed in the context of kappa in Altman [1991, 403–405]).

. use http://www.stata-press.com/data/r14/rate2
   (Altman p. 403)
. tabulate rada radb

<table>
<thead>
<tr>
<th>Radiologist A’s assessment</th>
<th>Radiologist B’s assessment</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal</td>
<td>21</td>
<td>33</td>
</tr>
<tr>
<td>benign</td>
<td>4</td>
<td>22</td>
</tr>
<tr>
<td>suspect</td>
<td>3</td>
<td>29</td>
</tr>
<tr>
<td>cancer</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Total</td>
<td>28</td>
<td>85</td>
</tr>
</tbody>
</table>

Our dataset contains two variables: rada, radiologist A’s assessment, and radb, radiologist B’s assessment. Each observation is a patient.

We can obtain the kappa measure of interrater agreement by typing

. kap rada radb

<table>
<thead>
<tr>
<th>Agreement</th>
<th>Expected Agreement</th>
<th>Kappa</th>
<th>Std. Err.</th>
<th>Z</th>
<th>Prob&gt;z</th>
</tr>
</thead>
<tbody>
<tr>
<td>63.53%</td>
<td>30.82%</td>
<td>0.4728</td>
<td>0.0694</td>
<td>6.81</td>
<td>0.0000</td>
</tr>
</tbody>
</table>

If each radiologist had made his determination randomly (but with probabilities equal to the overall proportions), we would expect the two radiologists to agree on 30.8% of the patients. In fact, they agreed on 63.5% of the patients, or 47.3% of the way between random agreement and perfect agreement. The amount of agreement indicates that we can reject the hypothesis that they are making their determinations randomly.
Example 2: Weighted kappa, prerecorded weight \( w \)

There is a difference between two radiologists disagreeing about whether a xeromammogram indicates cancer or the suspicion of cancer and disagreeing about whether it indicates cancer or is normal. The weighted kappa attempts to deal with this. \( \text{kap} \) provides two “prerecorded” weights, \( w \) and \( w2 \):

```
.kap rada radb, wgt(w)
Ratings weighted by:
1.0000 0.6667 0.3333 0.0000
0.6667 1.0000 0.6667 0.3333
0.3333 0.6667 1.0000 0.6667
0.0000 0.3333 0.6667 1.0000
Expected Agreement Agreement Kappa Std. Err. Z Prob>Z
86.67% 69.11% 0.5684 0.0788 7.22 0.0000
```

The \( w \) weights are given by \( 1 - |i - j|/(k - 1) \), where \( i \) and \( j \) index the rows of columns of the ratings by the two raters and \( k \) is the maximum number of possible ratings. The weighting matrix is printed above the table. Here the rows and columns of the \( 4 \times 4 \) matrix correspond to the ratings normal, benign, suspicious, and cancerous.

A weight of 1 indicates that an observation should count as perfect agreement. The matrix has 1s down the diagonals—when both radiologists make the same assessment, they are in agreement. A weight of, say, 0.6667 means that they are in two-thirds agreement. In our matrix, they get that score if they are “one apart”—one radiologist assesses cancer and the other is merely suspicious, or one is suspicious and the other says benign, and so on. An entry of 0.3333 means that they are in one-third agreement, or, if you prefer, two-thirds disagreement. That is the score attached when they are “two apart”. Finally, they are in complete disagreement when the weight is zero, which happens only when they are three apart—one says cancer and the other says normal.

Example 3: Weighted kappa, prerecorded weight \( w2 \)

The other prerecorded weight is \( w2 \), where the weights are given by \( 1 - \{(i - j)/(k - 1)\}^2 \):

```
.kap rada radb, wgt(w2)
Ratings weighted by:
1.0000 0.8889 0.5556 0.0000
0.8889 1.0000 0.8889 0.5556
0.5556 0.8889 1.0000 0.8889
0.0000 0.5556 0.8889 1.0000
Expected Agreement Agreement Kappa Std. Err. Z Prob>Z
94.77% 84.09% 0.6714 0.1079 6.22 0.0000
```

The \( w2 \) weight makes the categories even more alike and is probably inappropriate here.
Example 4: Weighted kappa, user-defined weights

In addition to using prerecorded weights, we can define our own weights with the `kapwgt` command. For instance, we might feel that suspicious and cancerous are reasonably similar, that benign and normal are reasonably similar, but that the suspicious/cancerous group is nothing like the benign/normal group:

```stata
.kapwgt xm 1 \ .8 1 \ 0 0 1 \ 0 0 .8 1
.kapwgt xm
1.0000
0.8000 1.0000
0.0000 0.0000 1.0000
0.0000 0.0000 0.8000 1.0000
```

We name the weights `xm`, and after the weight name, we enter the lower triangle of the weighting matrix, using \ to separate rows. We have four outcomes, so we continued entering numbers until we had defined the fourth row of the weighting matrix. If we type `kapwgt` followed by a name and nothing else, it shows us the weights recorded under that name. Satisfied that we have entered them correctly, we now use the weights to recalculate kappa:

```stata
.kap rada radb, wgt(xm)
```

Technical note

In addition to using weights for weighting the differences in categories, you can specify Stata’s traditional weights for weighting the data. In the examples above, we have 85 observations in our dataset—one for each patient. If we only knew the table of outcomes—that there were 21 patients rated normal by both radiologists, etc.—it would be easier to enter the table into Stata and work from it. The easiest way to enter the data is with `tabi`; see [R] `tabulate twoway`.

```stata
.tabi 21 12 0 0 \ 4 17 1 0 \ 3 9 15 2 \ 0 0 0 1, replace
total
```

`tabi` reported the Pearson $\chi^2$ for this table, but we do not care about it. The important thing is that, with the `replace` option, `tabi` left the table in memory:
The variable `row` is radiologist A’s assessment, `col` is radiologist B’s assessment, and `pop` is the number so assessed by both. Thus

```
.kap row col [freq=pop]
```

<table>
<thead>
<tr>
<th>Agreement</th>
<th>Expected</th>
<th>Kappa</th>
<th>Std. Err.</th>
<th>Z</th>
<th>Prob&gt;Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>63.53%</td>
<td>30.82%</td>
<td>0.4728</td>
<td>0.0694</td>
<td>6.81</td>
<td>0.0000</td>
</tr>
</tbody>
</table>

If we are going to keep these data, the names `row` and `col` are not indicative of what the data reflect. We could type (see [U] 12.6 Dataset, variable, and value labels)

```
rename row rada
rename col radb
label var rada "Radiologist A’s assessment"
label var radb "Radiologist B’s assessment"
label define assess 1 normal 2 benign 3 suspect 4 cancer
label values rada assess
label values radb assess
label data "Altman, page 403"
```

`kap`’s `tab` option, which can be used with or without weighted data, shows the table of assessments:

```
.kap rada radb [freq=pop], tab
```

<table>
<thead>
<tr>
<th>Radiologist A’s assessment</th>
<th>Radiologist B’s assessment</th>
<th>cancer</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>normal</td>
<td>21</td>
<td>12</td>
<td>0</td>
</tr>
<tr>
<td>benign</td>
<td>4</td>
<td>17</td>
<td>1</td>
</tr>
<tr>
<td>suspect</td>
<td>3</td>
<td>9</td>
<td>15</td>
</tr>
<tr>
<td>cancer</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Total</td>
<td>28</td>
<td>38</td>
<td>16</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Agreement</th>
<th>Expected</th>
<th>Kappa</th>
<th>Std. Err.</th>
<th>Z</th>
<th>Prob&gt;Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>63.53%</td>
<td>30.82%</td>
<td>0.4728</td>
<td>0.0694</td>
<td>6.81</td>
<td>0.0000</td>
</tr>
</tbody>
</table>
Technical note

You have data on individual patients. There are two raters, and the possible ratings are 1, 2, 3, and 4, but neither rater ever used rating 3:

```
.use http://www.stata-press.com/data/r14/rate2no3, clear
.tabulate ratera raterb
```

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>6</td>
<td>4</td>
<td>3</td>
<td>13</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
<td>3</td>
<td>3</td>
<td>11</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>1</td>
<td>26</td>
<td>28</td>
</tr>
<tr>
<td>Total</td>
<td>12</td>
<td>8</td>
<td>32</td>
<td>52</td>
</tr>
</tbody>
</table>

Here `kap` would determine that the ratings are from the set \{1, 2, 4\} because those were the only values observed. `kap` would expect a user-defined weighting matrix to be 3 \times 3, and if it were not, `kap` would issue an error message. In the formula-based weights, the calculation would be based on \(i, j = 1, 2, 3\) corresponding to the three observed ratings \{1, 2, 4\}.

Specifying the `absolute` option would clarify that the ratings are 1, 2, 3, and 4; it just so happens that rating 3 was never assigned. If a user-defined weighting matrix were also specified, `kap` would expect it to be 4 \times 4 or larger (larger because we can think of the ratings being 1, 2, 3, 4, 5, \ldots and it just so happens that ratings 5, 6, \ldots were never observed, just as rating 3 was not observed). In the formula-based weights, the calculation would be based on \(i, j = 1, 2, 4\).

```
.kap ratera raterb, wgt(w)
Ratings weighted by:
   1.0000  0.5000  0.0000
   0.5000  1.0000  0.5000
   0.0000  0.5000  1.0000
   Expected Agreement Agreement  Kappa  Std. Err.  Z  Prob>Z
   79.81%   57.17%   0.5285   0.1169   4.52   0.0000
```

```
.kap ratera raterb, wgt(w) absolute
Ratings weighted by:
   1.0000  0.6667  0.0000
   0.6667  1.0000  0.3333
   0.0000  0.3333  1.0000
   Expected Agreement Agreement  Kappa  Std. Err.  Z  Prob>Z
   81.41%   55.08%   0.5862   0.1209   4.85   0.0000
```

If all conceivable ratings are observed in the data, specifying `absolute` makes no difference. For instance, if rater A assigns ratings \{1, 2, 4\} and rater B assigns \{1, 2, 3, 4\}, the complete set of assigned ratings is \{1, 2, 3, 4\}, the same that `absolute` would specify. Without `absolute`, it makes no difference whether the ratings are coded \{1, 2, 3, 4\}, \{0, 1, 2, 3\}, \{1, 7, 9, 100\}, \{0, 1, 1.5, 2.0\}, or otherwise.
More than two raters

For more than two raters, the mathematics are such that the two raters are not considered unique. For instance, if there are three raters, there is no assumption that the three raters who rate the first subject are the same as the three raters who rate the second. Although we call this the “more than two raters” case, it can be used with two raters when the raters’ identities vary.

The nonunique rater case can be usefully broken down into three subcases: 1) there are two possible ratings, which we will call positive and negative; 2) there are more than two possible ratings, but the number of raters per subject is the same for all subjects; and 3) there are more than two possible ratings, and the number of raters per subject varies. kappa handles all these cases. To emphasize that there is no assumption of constant identity of raters across subjects, the variables specified contain counts of the number of raters rating the subject into a particular category.

Example 5: Two ratings

Fleiss, Levin, and Paik (2003, 612) offers the following hypothetical ratings by different sets of raters on 25 subjects:

<table>
<thead>
<tr>
<th>Subject</th>
<th>No. of raters</th>
<th>No. of pos. ratings</th>
<th>Subject</th>
<th>No. of raters</th>
<th>No. of pos. ratings</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>2</td>
<td>14</td>
<td>4</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>0</td>
<td>15</td>

</tr>
</tbody>
</table>

We have entered these data into Stata, and the variables are called subject, raters, and pos. kappa, however, requires that we specify variables containing the number of positive ratings and negative ratings, that is, pos and raters-pos:
. use http://www.stata-press.com/data/r14/p612
. generate neg = raters-pos
. kappa pos neg

Two-outcomes, multiple raters:

<table>
<thead>
<tr>
<th></th>
<th>Kappa</th>
<th>Z</th>
<th>Prob&gt;Z</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0.5415</td>
<td>5.28</td>
<td>0.0000</td>
</tr>
</tbody>
</table>

We would have obtained the same results if we had typed `kappa neg pos`.

Example 6: More than two ratings, constant number of raters, kappa

Each of 10 subjects is rated into one of three categories by five raters (Fleiss, Levin, and Paik 2003, 615):

. use http://www.stata-press.com/data/r14/p615, clear
. list

<table>
<thead>
<tr>
<th>subject</th>
<th>cat1</th>
<th>cat2</th>
<th>cat3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>1</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>2.</td>
<td>2</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>3.</td>
<td>3</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>4.</td>
<td>4</td>
<td>4</td>
<td>0</td>
</tr>
<tr>
<td>5.</td>
<td>5</td>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>6.</td>
<td>6</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>7.</td>
<td>7</td>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>8.</td>
<td>8</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>9.</td>
<td>9</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>10.</td>
<td>10</td>
<td>3</td>
<td>0</td>
</tr>
</tbody>
</table>

We obtain the kappa statistic:

. kappa cat1-cat3

<table>
<thead>
<tr>
<th>Outcome</th>
<th>Kappa</th>
<th>Z</th>
<th>Prob&gt;Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat1</td>
<td>0.2917</td>
<td>2.92</td>
<td>0.0018</td>
</tr>
<tr>
<td>cat2</td>
<td>0.6711</td>
<td>6.71</td>
<td>0.0000</td>
</tr>
<tr>
<td>cat3</td>
<td>0.3490</td>
<td>3.49</td>
<td>0.0002</td>
</tr>
</tbody>
</table>

| combined | 0.4179 | 5.83 | 0.0000 |

The first part of the output shows the results of calculating kappa for each of the categories separately against an amalgam of the remaining categories. For instance, the `cat1` line is the two-rating kappa, where positive is `cat1` and negative is `cat2` or `cat3`. The test statistic, however, is calculated differently (see Methods and formulas). The combined kappa is the appropriately weighted average of the individual kappas. There is considerably less agreement about the rating of subjects into the first category than there is for the second.
Example 7: More than two ratings, constant number of raters, kap

Now suppose that we have the same data as in the previous example but that the data are organized differently:

```
. use http://www.stata-press.com/data/r14/p615b
. list

<table>
<thead>
<tr>
<th>subject</th>
<th>rater1</th>
<th>rater2</th>
<th>rater3</th>
<th>rater4</th>
<th>rater5</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>2</td>
<td>2</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>1</td>
<td>1</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>5</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>6</td>
<td>6</td>
<td>1</td>
<td>2</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>7</td>
<td>7</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>8</td>
<td>2</td>
<td>2</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>9</td>
<td>9</td>
<td>1</td>
<td>3</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>10</td>
<td>10</td>
<td>1</td>
<td>1</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>
```

Here we would use *kap* rather than *kappa* because the variables record ratings for each rater.

```
. kap rater1 rater2 rater3 rater4 rater5
There are 5 raters per subject:

<table>
<thead>
<tr>
<th>Outcome</th>
<th>Kappa</th>
<th>Z</th>
<th>Prob&gt;Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.2917</td>
<td>2.92</td>
<td>0.0018</td>
</tr>
<tr>
<td>2</td>
<td>0.6711</td>
<td>6.71</td>
<td>0.0000</td>
</tr>
<tr>
<td>3</td>
<td>0.3490</td>
<td>3.49</td>
<td>0.0002</td>
</tr>
</tbody>
</table>
```

It does not matter which rater is which when there are more than two raters.

Example 8: More than two ratings, varying number of raters, kappa

In this unfortunate case, kappa can be calculated, but there is no test statistic for testing against $\kappa > 0$. We do nothing differently—*kappa* calculates the total number of raters for each subject, and, if it is not a constant, *kappa* suppresses the calculation of test statistics.
. use http://www.stata-press.com/data/r14/rvary
. list

<td>0.2938</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>combined</td>
<td>0.3816</td>
<td>.</td>
<td>.</td>
</tr>
</tbody>
</table>

Note: Number of ratings per subject vary; cannot calculate test statistics.

Example 9: More than two ratings, varying number of raters, kap

This case is similar to the previous example, but the data are organized differently:

. use http://www.stata-press.com/data/r14/rvary2
. list

<table>
<thead>
<tr>
<th>subject</th>
<th>rater1</th>
<th>rater2</th>
<th>rater3</th>
<th>rater4</th>
<th>rater5</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>2</td>
<td>2</td>
<td>.</td>
</tr>
<tr>

<td>5</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>6</td>
<td>6</td>
<td>1</td>
<td>2</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>7</td>
<td>7</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>8</td>
<td>2</td>
<td>2</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>9</td>
<td>9</td>
<td>1</td>
<td>3</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>10</td>
<td>10</td>
<td>1</td>
<td>1</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>
Here we specify \texttt{kap} instead of \texttt{kappa} because the variables record ratings for each rater.

```
.kap rater1-rater5
```

There are between 3 and 5 (median = 5.00) raters per subject:

<table>
<thead>
<tr>
<th>Outcome</th>
<th>Kappa</th>
<th>Z</th>
<th>Prob&gt;Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0.2685</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>2</td>
<td>0.6457</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>3</td>
<td>0.2938</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>combined</td>
<td>0.3816</td>
<td>.</td>
<td>.</td>
</tr>
</tbody>
</table>

Note: Number of ratings per subject vary; cannot calculate test statistics.

### Stored results

\texttt{kap} and \texttt{kappa} store the following in \texttt{r()}:

<table>
<thead>
<tr>
<th>Scalars</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{r(N)}</td>
<td>number of subjects (\texttt{kap} only)</td>
</tr>
<tr>
<td>\texttt{r(prop_o)}</td>
<td>observed proportion of agreement (\texttt{kap} only)</td>
</tr>
<tr>
<td>\texttt{r(prop_e)}</td>
<td>expected proportion of agreement (\texttt{kap} only)</td>
</tr>
<tr>
<td>\texttt{r(kappa)}</td>
<td>kappa</td>
</tr>
<tr>
<td>\texttt{r(z)}</td>
<td>(z) statistic</td>
</tr>
<tr>
<td>\texttt{r(se)}</td>
<td>standard error for kappa statistic</td>
</tr>
</tbody>
</table>

### Methods and formulas

The kappa statistic was first proposed by Cohen (1960). The generalization for weights reflecting the relative seriousness of each possible disagreement is due to Cohen (1968). The analysis-of-variance approach for \(k = 2\) and \(m \geq 2\) is due to Landis and Koch (1977b). See Altman (1991, 403–409) or Dunn (2000, chap. 2) for an introductory treatment and Fleiss, Levin, and Paik (2003, chap. 18) for a more detailed treatment. All formulas below are as presented in Fleiss, Levin, and Paik (2003). Let \(m\) be the number of raters, and let \(k\) be the number of rating outcomes.

Methods and formulas are presented under the following headings:

- \texttt{kap: m = 2}
- \texttt{kappa: m > 2, k = 2}
- \texttt{kappa: m > 2, k > 2}

#### \texttt{kap: m = 2}

Define \(w_{ij} (i = 1, \ldots, k \text{ and } j = 1, \ldots, k)\) as the weights for agreement and disagreement (\texttt{wgt()}), or, if the data are not weighted, define \(w_{ii} = 1\) and \(w_{ij} = 0\) for \(i \neq j\). If \texttt{wgt(w)} is specified, \(w_{ij} = 1 - |i - j|/(k - 1)\). If \texttt{wgt(w2)} is specified, \(w_{ij} = 1 - \{(i - j)/(k - 1)\}^2\).

The observed proportion of agreement is

\[
p_o = \sum_{i=1}^{k} \sum_{j=1}^{k} w_{ij} p_{ij}
\]
where \( p_{ij} \) is the fraction of ratings \( i \) by the first rater and \( j \) by the second. The expected proportion of agreement is

\[
p_e = \sum_{i=1}^{k} \sum_{j=1}^{k} w_{ij} p_i \cdot p_j
\]

where \( p_i = \sum_j p_{ij} \) and \( p_j = \sum_i p_{ij} \).

Kappa is given by

\[
\hat{\kappa} = \frac{p_o - p_e}{1 - p_e}
\]

The standard error of \( \hat{\kappa} \) for testing against 0 is

\[
\hat{s}_0 = \frac{1}{(1 - p_e) \sqrt{n}} \left( \left[ \sum_i \sum_j p_i \cdot p_j \{ w_{ij} - (\bar{w}_i + \bar{w}_j)^2 \} \right]^2 - p_e^2 \right)^{1/2}
\]

where \( n \) is the number of subjects being rated, \( \bar{w}_i = \sum_j p_j w_{ij} \), and \( \bar{w}_j = \sum_i p_i w_{ij} \). The test statistic \( Z = \hat{\kappa}/\hat{s}_0 \) is assumed to be distributed \( N(0, 1) \).

**kappa: \( m > 2, k = 2 \)**

Each subject \( i, i = 1, \ldots, n \), is found by \( x_i \) of \( m_i \) raters to be positive (the choice as to what is labeled positive is arbitrary).

The overall proportion of positive ratings is \( \bar{p} = \sum_i x_i / (n \bar{m}) \), where \( \bar{m} = \sum_i m_i / n \). The between-subjects mean square is (approximately)

\[
B = \frac{1}{n} \sum_i \frac{(x_i - m_i \bar{p})^2}{m_i}
\]

and the within-subject mean square is

\[
W = \frac{1}{n(\bar{m} - 1)} \sum_i x_i (m_i - x_i)
\]

Kappa is then defined as

\[
\hat{\kappa} = \frac{B - W}{B + (\bar{m} - 1)W}
\]

The standard error for testing against 0 (Fleiss and Cuzick 1979) is approximately equal to and is calculated as

\[
\hat{s}_0 = \frac{1}{(\bar{m} - 1) \sqrt{n \bar{m}_H}} \left\{ 2(\bar{m}_H - 1) + \frac{(\bar{m} - \bar{m}_H)(1 - 4\bar{p} \bar{q})}{\bar{m} \bar{p} \bar{q}} \right\}^{1/2}
\]

where \( \bar{m}_H \) is the harmonic mean of \( m_i \) and \( \bar{q} = 1 - \bar{p} \).

The test statistic \( Z = \hat{\kappa}/\hat{s}_0 \) is assumed to be distributed \( N(0, 1) \).
kappa: $m > 2, k > 2$

Let $x_{ij}$ be the number of ratings on subject $i$, $i = 1, \ldots, n$, into category $j$, $j = 1, \ldots, k$. Define $\bar{p}_j$ as the overall proportion of ratings in category $j$, $\bar{q}_j = 1 - \bar{p}_j$, and let $\hat{\kappa}_j$ be the kappa statistic given above for $k = 2$ when category $j$ is compared with the amalgam of all other categories. Kappa is

$$\kappa = \frac{\sum_j \bar{p}_j \bar{q}_j \hat{\kappa}_j}{\sum_j \bar{p}_j \bar{q}_j}$$

(Landis and Koch 1977b). In the case where the number of raters per subject, $\sum_j x_{ij}$, is a constant $m$ for all $i$, Fleiss, Nee, and Landis (1979) derived the following formulas for the approximate standard errors. The standard error for testing $\hat{\kappa}_j$ against 0 is

$$\hat{s}_j = \left\{ \frac{2}{nm(m - 1)} \right\}^{1/2}$$

and the standard error for testing $\kappa$ is

$$s = \frac{\sqrt{2}}{\sum_j \bar{p}_j \bar{q}_j \sqrt{nm(m - 1)}} \left\{ \left( \sum_j \bar{p}_j \bar{q}_j \right)^2 - \sum_j \bar{p}_j \bar{q}_j (\bar{q}_j - \bar{p}_j) \right\}^{1/2}$$

**kdensity** — Univariate kernel density estimation

### Description

kdensity produces kernel density estimates and graphs the result.

### Quick start

Graph of the kernel density estimate for \( v1 \)

kdensity \( v1 \)

Add a normal curve

kdensity \( v1 \), normal

With a kernel bandwidth of 2

kdensity \( v1 \), bwidth(2)

Gaussian kernel function for \( v1 \)

kdensity \( v1 \), kernel(gaussian)

Kernel density estimate for \( v1 \) and \( v2 \) in the same graph area

twoway kdensity \( v1 \) || kdensity \( v2 \)

Separate graphs of kernel density estimate of \( v1 \) for each level of \( \text{catvar} \)

twoway kdensity \( v1 \), by(catvar)

Kernel density estimates of \( v1 \) for \( \text{catvar} = 0 \) and 1 in the same graph area

twoway kdensity \( v1 \) if catvar==0 || kdensity \( v1 \) if catvar==1

## Options

**Main**

kernel(kernel) specifies the kernel function for use in calculating the kernel density estimate. The default kernel is the Epanechnikov kernel (epanechnikov).
bwidth(#) specifies the half-width of the kernel, the width of the density window around each point. If bwidth() is not specified, the “optimal” width is calculated and used. The optimal width is the width that would minimize the mean integrated squared error if the data were Gaussian and a Gaussian kernel were used, so it is not optimal in any global sense. In fact, for multimodal and highly skewed densities, this width is usually too wide and oversmooths the density (Silverman 1986).

generate(newvar\_x, newvar\_d) stores the results of the estimation. newvar\_x will contain the points at which the density is estimated. newvar\_d will contain the density estimate.

n(#) specifies the number of points at which the density estimate is to be evaluated. The default is min(N, 50), where N is the number of observations in memory.

at(var\_x) specifies a variable that contains the values at which the density should be estimated. This option allows you to more easily obtain density estimates for different variables or different subsamples of a variable and then overlay the estimated densities for comparison.

nograph suppresses the graph. This option is often used with the generate() option.

cline\_options affect the rendition of the plotted kernel density estimate. See [G-3] cline\_options.

Density plots

normal requests that a normal density be overlaid on the density estimate for comparison.

normopts(cline\_options) specifies details about the rendition of the normal curve, such as the color and style of line used. See [G-3] cline\_options.

student(#) specifies that a Student’s t density with # degrees of freedom be overlaid on the density estimate for comparison.

stopts(cline\_options) affects the rendition of the Student’s t density. See [G-3] cline\_options.

Add plots

addplot(plot) provides a way to add other plots to the generated graph. See [G-3] addplot\_option.

Y axis, X axis, Titles, Legend, Overall

twoway\_options are any of the options documented in [G-3] twoway\_options, excluding by(). These include options for titling the graph (see [G-3] title\_options) and for saving the graph to disk (see [G-3] saving\_option).

Remarks and examples

Kernel density estimators approximate the density \( f(x) \) from observations on \( x \). Histograms do this, too, and the histogram itself is a kind of kernel density estimate. The data are divided into nonoverlapping intervals, and counts are made of the number of data points within each interval. Histograms are bar graphs that depict these frequency counts—the bar is centered at the midpoint of each interval—and its height reflects the average number of data points in the interval.

In more general kernel density estimates, the range is still divided into intervals, and estimates of the density at the center of intervals are produced. One difference is that the intervals are allowed to overlap. We can think of sliding the interval—called a window—along the range of the data and collecting the center-point density estimates. The second difference is that, rather than merely counting the number of observations in a window, a kernel density estimator assigns a weight between
0 and 1—based on the distance from the center of the window—and sums the weighted values. The function that determines these weights is called the kernel.

Kernel density estimates have the advantages of being smooth and of being independent of the choice of origin (corresponding to the location of the bins in a histogram).

See Salgado-Ugarte, Shimizu, and Taniuchi (1993) and Fox (1990) for discussions of kernel density estimators that stress their use as exploratory data-analysis tools.

Cox (2007) gives a lucid introductory tutorial on kernel density estimation with several Stata produced examples. He provides tips and tricks for working with skewed or bounded distributions and applying the same techniques to estimate the intensity function of a point process.

Example 1: Histogram and kernel density estimate

Goeden (1978) reports data consisting of 316 length observations of coral trout. We wish to investigate the underlying density of the lengths. To begin on familiar ground, we might draw a histogram. In [R] `histogram`, we suggest setting the bins to \( \min(\sqrt{n}, 10 \cdot \log_{10} n) \), which for \( n = 316 \) is roughly 18:

```stata
use http://www.stata-press.com/data/r14/trocolen
.histogram length, bin(18)
(bin=18, start=226, width=19.777778)
```

![Histogram and kernel density estimate](image)
The kernel density estimate, on the other hand, is smooth.

```
. kdensity length
```

Kernel density estimators are, however, sensitive to an assumption, just as are histograms. In histograms, we specify a number of bins. For kernel density estimators, we specify a width. In the graph above, we used the default width. `kdensity` is smarter than `twoway histogram` in that its default width is not a fixed constant. Even so, the default width is not necessarily best.

`kdensity` stores the width in the returned scalar `bwidth`, so typing `display r(bwidth)` reveals it. Doing this, we discover that the width is approximately 20.

Widths are similar to the inverse of the number of bins in a histogram in that smaller widths provide more detail. The units of the width are the units of \( x \), the variable being analyzed. The width is specified as a half-width, meaning that the kernel density estimator with half-width 20 corresponds to sliding a window of size 40 across the data.

We can specify half-widths for ourselves by using the `bwidth()` option. Smaller widths do not smooth the density as much:

```
. kdensity length, bwidth(10)
```

```
Example 2: Different kernels can produce different results

When widths are held constant, different kernels can produce surprisingly different results. This is really an attribute of the kernel and width combination; for a given width, some kernels are more sensitive than others at identifying peaks in the density estimate.

We can see this when using a dataset with lots of peaks. In the automobile dataset, we characterize the density of weight, the weight of the vehicles. Below we compare the Epanechnikov and Parzen kernels.

```
. use http://www.stata-press.com/data/r14/auto
   (1978 Automobile Data)
. kdensity weight, kernel(epanechnikov) nograph generate(x epan)
. kdensity weight, kernel(parzen) nograph generate(x2 parzen)
. label var epan "Epanechnikov density estimate"
. label var parzen "Parzen density estimate"
. line epan parzen x, sort ytitle(Density) legend(cols(1))
```
We did not specify a width, so we obtained the default width. That width is not a function of the selected kernel, but of the data. See *Methods and formulas* for the calculation of the optimal width.

> Example 3: Density with overlaid normal density

In examining the density estimates, we may wish to overlay a normal density or a Student’s $t$ density for comparison. Using automobile weights, we can get an idea of the distance from normality by using the `normal` option.

```stata
.kdensity weight, kernel(epanechnikov) normal
```

> Example 4: Compare two densities

We also may want to compare two or more densities. In this example, we will compare the density estimates of the weights for the foreign and domestic cars.

```stata
use http://www.stata-press.com/data/r14/auto, clear
(1978 Automobile Data)
.kdensity weight, nograph generate(x fx)
.kdensity weight if foreign==0, nograph generate(fx0) at(x)
.kdensity weight if foreign==1, nograph generate(fx1) at(x)
.label var fx0 "Domestic cars"
.label var fx1 "Foreign cars"
```
. line fx0 fx1 x, sort ytitle(Density)

Technical note

Although all the examples we included had densities of less than 1, the density may exceed 1.

The probability density $f(x)$ of a continuous variable, $x$, has the units and dimensions of the reciprocal of $x$. If $x$ is measured in meters, $f(x)$ has units $1$/meter. Thus the density is not measured on a probability scale, so it is possible for $f(x)$ to exceed 1.

To see this, think of a uniform density on the interval 0 to 1. The area under the density curve is 1: this is the product of the density, which is constant at 1, and the range, which is 1. If the variable is then transformed by doubling, the area under the curve remains 1 and is the product of the density, constant at 0.5, and the range, which is 2. Conversely, if the variable is transformed by halving, the area under the curve also remains at 1 and is the product of the density, constant at 2, and the range, which is 0.5. (Strictly, the range is measured in certain units, and the density is measured in the reciprocal of those units, so the units cancel on multiplication.)

Stored results

kdensity stores the following in r():

Scalars

- r(bwidth)    kernel bandwidth
- r(n)         number of points at which the estimate was evaluated
- r(scale)     density bin width

Macros

- r(kernel)    name of kernel
Methods and formulas

A kernel density estimate is formed by summing the weighted values calculated with the kernel function \( K \), as in

\[
\hat{f}_K = \frac{1}{qh} \sum_{i=1}^{n} w_i K\left(\frac{x - X_i}{h}\right)
\]

where \( q = \sum w_i \) if weights are frequency weights (fweight) or analytic weights (aweight), and \( q = 1 \) if weights are importance weights (iweight). Analytic weights are rescaled so that \( \sum w_i = n \) (see [U] 11 Language syntax). If weights are not used, then \( w_i = 1 \), for \( i = 1, \ldots, n \). \( \text{kdensity} \) includes seven different kernel functions. The Epanechnikov is the default function if no other kernel is specified and is the most efficient in minimizing the mean integrated squared error.

<table>
<thead>
<tr>
<th>Kernel</th>
<th>Formula</th>
</tr>
</thead>
</table>
| Biweight        | \( K[z] = \begin{cases} 
\frac{15}{16} (1 - z^2)^2 & \text{if } |z| < 1 \\
0 & \text{otherwise} 
\end{cases} \) |
| Cosine          | \( K[z] = \begin{cases} 
1 + \cos(2\pi z) & \text{if } |z| < 1/2 \\
0 & \text{otherwise} 
\end{cases} \) |
| Epanechnikov    | \( K[z] = \begin{cases} 
\frac{3}{4} (1 - \frac{1}{5} z^2) / \sqrt{5} & \text{if } |z| < \sqrt{5} \\
0 & \text{otherwise} 
\end{cases} \) |
| Epan2           | \( K[z] = \begin{cases} 
\frac{3}{4} (1 - z^2) & \text{if } |z| < 1 \\
0 & \text{otherwise} 
\end{cases} \) |
| Gaussian        | \( K[z] = \frac{1}{\sqrt{2\pi}} e^{-z^2/2} \) |
| Parzen          | \( K[z] = \begin{cases} 
\frac{4}{3} - 8z^2 + 8|z|^3 & \text{if } |z| \leq 1/2 \\
8(1 - |z|)^3/3 & \text{if } 1/2 < |z| \leq 1 \\
0 & \text{otherwise} 
\end{cases} \) |
| Rectangular     | \( K[z] = \begin{cases} 
1/2 & \text{if } |z| < 1 \\
0 & \text{otherwise} 
\end{cases} \) |
| Triangular      | \( K[z] = \begin{cases} 
1 - |z| & \text{if } |z| < 1 \\
0 & \text{otherwise} 
\end{cases} \) |

From the definitions given in the table, we can see that the choice of \( h \) will drive how many values are included in estimating the density at each point. This value is called the window width or bandwidth. If the window width is not specified, it is determined as

\[
m = \min\left(\sqrt{\text{variance}_x}, \frac{\text{interquartile range}_x}{1.349}\right)
\]

\[
h = \frac{0.9m}{n^{1/5}}
\]

where \( x \) is the variable for which we wish to estimate the kernel and \( n \) is the number of observations.

Most researchers agree that the choice of kernel is not as important as the choice of bandwidth. There is a great deal of literature on choosing bandwidths under various conditions; see, for example, Parzen (1962) or Tapia and Thompson (1978). Also see Newton (1988) for a comparison with sample spectral density estimation in time-series applications.
Acknowledgments

We gratefully acknowledge the previous work by Isaías H. Salgado-Ugarte of Universidad Nacional Autónoma de México, and Makoto Shimizu and Toru Taniuchi of the University of Tokyo; see Salgado-Ugarte, Shimizu, and Taniuchi (1993). Their article provides a good overview of the subject of univariate kernel density estimation and presents arguments for its use in exploratory data analysis.

### Description

`ksmirnov` performs one- and two-sample Kolmogorov–Smirnov tests of the equality of distributions. A one-sample test compares the distribution of the tested variable with the specified distribution. A two-sample test tests the equality of the distributions of two samples.

When testing for normality, please see [R] `sktest` and [R] `swilk`.

### Quick start

**One-sample test comparing the distribution of v1 with a Student’s t distribution with 5 degrees of freedom**

```stata
ksmirnov v1 = t(5,v1)
```

**Two-sample test comparing distributions of v2 in two groups defined by catvar**

```stata
ksmirnov v2, by(catvar)
```

As above, but calculate an exact p-value

```stata
ksmirnov v2, by(catvar) exact
```

### Menu

Statistics > Nonparametric analysis > Tests of hypotheses > Kolmogorov-Smirnov test
Syntax

One-sample Kolmogorov–Smirnov test

\texttt{ksmirnov varname = exp [if] [in]}

Two-sample Kolmogorov–Smirnov test

\texttt{ksmirnov varname [if] [in], by(groupvar) [ exact ]}

In the first syntax, \textit{varname} is the variable whose distribution is being tested, and \textit{exp} must evaluate to the corresponding (theoretical) cumulative. In the second syntax, \textit{groupvar} must take on two distinct values. The distribution of \textit{varname} for the first value of \textit{groupvar} is compared with that of the second value.

Options for two-sample test

\underline{Main}

\texttt{by(groupvar)} is required. It specifies a binary variable that identifies the two groups. \texttt{exact} specifies that the exact \textit{p}-value be computed.

Remarks and examples

\textbf{Example 1: Two-sample test}

Say that we have data on \textit{x} that resulted from two different experiments, labeled as \texttt{group==1} and \texttt{group==2}. Our data contain

\begin{verbatim}
  . use http://www.stata-press.com/data/r14/ksxmpl
  . list

  +-------------+-----+
  | group | x   |
  |-------+-----|
  | 1     |  2  |
  | 2     |  0  |
  | 3     |  3  |
  | 4     |  4  |
  | 5     |  5  |
  | 6     |  8  |
  | 7     | 10  |
  +-------------+-----+
\end{verbatim}

We wish to use the two-sample Kolmogorov–Smirnov test to determine if there are any differences in the distribution of \textit{x} for these two groups:

\begin{verbatim}
  . ksmirnov x, by(group)
  Two-sample Kolmogorov-Smirnov test for equality of distribution functions

  Small group       D    P-value
  +-------+-------+-------+
  1:     0.5000  0.424
  2:     -0.1667 0.909
  Combined K-S:  0.5000  0.785
  +-------+-------+-------+
\end{verbatim}
The first line tests the hypothesis that \( x \) for group 1 contains *smaller* values than for group 2. The largest difference between the distribution functions is 0.5. The approximate asymptotic \( p \)-value for this is 0.424, which is not significant.

The second line tests the hypothesis that \( x \) for group 1 contains *larger* values than for group 2. The largest difference between the distribution functions in this direction is 0.1667. The approximate asymptotic \( p \)-value for this small difference is 0.909.

Finally, the approximate asymptotic \( p \)-value for the combined test is 0.785. The approximate \( p \)-values \texttt{ksmirnov} calculates are based on the five-term approximation of the asymptotic distributions derived by Smirnov (1933). These approximations are not good for small samples (\( n < 50 \)). They are too conservative.

An exact \( p \)-value can be calculated using the \texttt{exact} option:

\[
\texttt{. ksmirnov x, by(group) exact}
\]

Two-sample Kolmogorov-Smirnov test for equality of distribution functions

<table>
<thead>
<tr>
<th>Smaller group</th>
<th>D</th>
<th>P-value</th>
<th>Exact</th>
</tr>
</thead>
<tbody>
<tr>
<td>1:</td>
<td>0.5000</td>
<td>0.424</td>
<td></td>
</tr>
<tr>
<td>2:</td>
<td>-0.1667</td>
<td>0.909</td>
<td></td>
</tr>
<tr>
<td>Combined K-S:</td>
<td>0.5000</td>
<td>0.785</td>
<td>0.657</td>
</tr>
</tbody>
</table>

\[\text{Example 2: One-sample test}\]

Let’s now test whether \( x \) in the example above is distributed normally. Kolmogorov–Smirnov is not a particularly powerful test in testing for normality, and we do not endorse such use of it; see \texttt{[R] sktest} and \texttt{[R] swilk} for better tests.

In any case, we will test against a normal distribution with the same mean and standard deviation:

\[
\texttt{. summarize x}
\]

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>7</td>
<td>4.571429</td>
<td>3.457222</td>
<td>0</td>
<td>10</td>
</tr>
</tbody>
</table>

\[
\texttt{. ksmirnov x = normal((x-4.571429)/3.457222)}
\]

One-sample Kolmogorov-Smirnov test against theoretical distribution \( \text{normal}((x-4.571429)/3.457222) \)

<table>
<thead>
<tr>
<th>Smaller group</th>
<th>D</th>
<th>P-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>x:</td>
<td>0.1650</td>
<td>0.683</td>
</tr>
<tr>
<td>Cumulative:</td>
<td>-0.1250</td>
<td>0.803</td>
</tr>
<tr>
<td>Combined K-S:</td>
<td>0.1650</td>
<td>0.991</td>
</tr>
</tbody>
</table>

Because Stata has no way of knowing that we based this calculation on the calculated mean and standard deviation of \( x \), the \( p \)-values will be slightly conservative in addition to being approximations. Nevertheless, they clearly indicate that the data cannot be distinguished from normally distributed data.
Stored results

ksmirnov stores the following in r():

Scalars
- r(D_1) D from line 1
- r(p_1) p-value from line 1
- r(D_2) D from line 2
- r(p_2) p-value from line 2
- r(D) combined D
- r(p) combined p-value
- r(p_exact) exact combined p-value

Macros
- r(group1) name of group from line 1
- r(group2) name of group from line 2

Methods and formulas

In general, the Kolmogorov–Smirnov test (Kolmogorov 1933; Smirnov 1933; also see Conover [1999], 428–465) is not very powerful against differences in the tails of distributions. In return for this, it is fairly powerful for alternative hypotheses that involve lumpiness or clustering in the data.

The directional hypotheses are evaluated with the statistics

\[ D^+ = \max_x \left\{ F(x) - G(x) \right\} \]
\[ D^- = \min_x \left\{ F(x) - G(x) \right\} \]

where \( F(x) \) and \( G(x) \) are the empirical distribution functions for the sample being compared. The combined statistic is

\[ D = \max \left( |D^+|, |D^-| \right) \]

The \( p \)-value for this statistic may be obtained by evaluating the asymptotic limiting distribution. Let \( m \) be the sample size for the first sample, and let \( n \) be the sample size for the second sample. Smirnov (1933) shows that

\[ \lim_{m,n \to \infty} \Pr \left\{ \sqrt{mn/(m+n)}D_{m,n} \leq z \right\} = 1 - 2 \sum_{i=1}^{\infty} (-1)^{i-1} \exp(-2i^2z^2) \]

The first five terms form the approximation \( P_a \) used by Stata. The exact \( p \)-value is calculated by a counting algorithm; see Gibbons and Chakraborti (2011, 236–238).
Andrei Nikolayevich Kolmogorov (1903–1987), of Russia, was one of the great mathematicians of the twentieth century, making outstanding contributions in many different branches, including set theory, measure theory, probability and statistics, approximation theory, functional analysis, classical dynamics, and theory of turbulence. He was a faculty member at Moscow State University for more than 60 years.

Nikolai Vasilyevich Smirnov (1900–1966) was a Russian statistician whose work included contributions in nonparametric statistics, order statistics, and goodness of fit. After army service and the study of philosophy and philology, he turned to mathematics and eventually rose to be head of mathematical statistics at the Steklov Mathematical Institute in Moscow.

**Title**

```plaintext
kwallis — Kruskal–Wallis equality-of-populations rank test
```

### Description

`kwallis` performs a Kruskal–Wallis test of the hypothesis that several samples are from the same population. This test is a multisample generalization of the two-sample Wilcoxon (Mann–Whitney) rank-sum test.

### Quick start

Test the equality of distribution of `v1` across all levels of categorical variable `cvar`

```plaintext
kwallis v1, by(cvar)
```

As above, but perform the test only for observations with `v2 = 1`

```plaintext
kwallis v1 if v2==1, by(cvar)
```

### Menu

```
Statistics > Nonparametric analysis > Tests of hypotheses > Kruskal-Wallis rank test
```

### Syntax

```plaintext
kwallis varname [if] [in], by(groupvar)
```

### Option

`by(groupvar)` is required. It specifies a variable that identifies the groups.

### Remarks and examples

#### Example 1

We have data on the 50 states. The data contain the median age of the population, `medage`, and the region of the country, `region`, for each state. We wish to test for the equality of the median age distribution across all four regions simultaneously:
. use http://www.stata-press.com/data/r14/census
(1980 Census data by state)
. kwallis medage, by(region)
Kruskal–Wallis equality-of-populations rank test

<table>
<thead>
<tr>
<th>region</th>
<th>Obs</th>
<th>Rank Sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>NE</td>
<td>9</td>
<td>376.50</td>
</tr>
<tr>
<td>N Cntrl</td>
<td>12</td>
<td>294.00</td>
</tr>
<tr>
<td>South</td>
<td>16</td>
<td>398.00</td>
</tr>
<tr>
<td>West</td>
<td>13</td>
<td>206.50</td>
</tr>
</tbody>
</table>

chi-squared = 17.041 with 3 d.f.
probability = 0.0007
chi-squared with ties = 17.062 with 3 d.f.
probability = 0.0007

From the output, we see that we can reject the hypothesis that the populations are the same at any level below 0.07%.

Stored results

kwallis stores the following in r():
Scalars
- r(df) degrees of freedom
- r(chi2) \( \chi^2 \)
- r(chi2_adj) \( \chi^2 \) adjusted for ties

Methods and formulas

The Kruskal–Wallis test (Kruskal and Wallis 1952, 1953; also see Altman [1991, 213–215]; Conover [1999, 288–297]; and Riffenburgh [2012, sec. 11.6]) is a multiple-sample generalization of the two-sample Wilcoxon (also called Mann–Whitney) rank-sum test (Wilcoxon 1945; Mann and Whitney 1947). Samples of sizes \( n_j, j = 1, \ldots, m \), are combined and ranked in ascending order of magnitude. Tied values are assigned the average ranks. Let \( n \) denote the overall sample size, and let \( R_j = \sum_{i=1}^{n_j} R(X_{ji}) \) denote the sum of the ranks for the \( j \)th sample. The Kruskal–Wallis one-way analysis-of-variance test, \( H \), is defined as

\[
H = \frac{1}{S^2} \left\{ \sum_{j=1}^{m} \frac{R_j^2}{n_j} - \frac{n(n+1)^2}{4} \right\}
\]

where

\[
S^2 = \frac{1}{n-1} \left\{ \sum_{\text{all ranks}} R(X_{ji})^2 - \frac{n(n+1)^2}{4} \right\}
\]

If there are no ties, this equation simplifies to

\[
H = \frac{12}{n(n+1)} \sum_{j=1}^{m} \frac{R_j^2}{n_j} - 3(n+1)
\]

The sampling distribution of \( H \) is approximately \( \chi^2 \) with \( m - 1 \) degrees of freedom.
William Henry Kruskal (1919–2005) was born in New York City. He studied mathematics and statistics at Antioch College, Harvard, and Columbia, and joined the University of Chicago in 1951. He made many outstanding contributions to linear models, nonparametric statistics, government statistics, and the history and methodology of statistics.

Wilson Allen Wallis (1912–1998) was born in Philadelphia. He studied psychology and economics at the Universities of Minnesota and Chicago and at Columbia. He taught at Yale, Stanford, and Chicago, before moving as president (later chancellor) to the University of Rochester in 1962. He also served in several Republican administrations. Wallis served as editor of the *Journal of the American Statistical Association*, coauthored a popular introduction to statistics, and contributed to nonparametric statistics.

ladder searches a subset of the ladder of powers (Tukey 1977) for a transform that converts varname into a normally distributed variable.

gladder and qladder each display a graph matrix. gladder displays nine histograms of transforms of varname according to the ladder of powers. qladder displays the quantiles of transforms of varname according to the ladder of powers against the quantiles of a normal distribution.

**Quick start**

Table showing Tukey’s ladder of powers transformations for v

```
  ladder v
```

As above, but with separate tables for each level of the categorical variable catvar

```
  by catvar: ladder v
```

Display transformations graphically using histograms

```
  gladder v
```

As above, but using quantile plots

```
  qladder v
```

**Menu**

**ladder**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Ladder of powers

**gladder**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Ladder-of-powers histograms

**qladder**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Ladder-of-powers quantile-normal plots
Syntax

Ladder of powers

```plaintext
ladder varname [if] [in] [, generate(newvar) noadjust]
```

Ladder-of-powers histograms

```plaintext
gladder varname [if] [in] [, histogram_options combine_options]
```

Ladder-of-powers quantile–normal plots

```plaintext
qladder varname [if] [in] [, qnorm_options combine_options]
```

by is allowed with ladder; see [D] by.

Options for ladder

- **generate(newvar)** saves the transformed values corresponding to the minimum chi-squared value from the table. We do not recommend using generate() because it is literal in interpreting the minimum, thus ignoring nearly equal but perhaps more interpretable transforms.

- **noadjust** is the noadjust option to sktest; see [R] sktest.

Options for gladder

- **histogram_options** affect the rendition of the histograms across all relevant transformations; see [R] histogram. Here the normal option is assumed, so you must supply the nonormal option to suppress the overlaid normal density. Also, gladder does not allow the width(#) option of histogram.

- **combine_options** are any of the options documented in [G-2] graph combine. These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

Options for qladder

- **qnorm_options** affect the rendition of the quantile–normal plots across all relevant transformations. See [R] diagnostic plots.

- **combine_options** are any of the options documented in [G-2] graph combine. These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).
Remarks and examples

> Example 1: ladder

We have data on the mileage rating of 74 automobiles and wish to find a transform that makes
the variable normally distributed:

```plaintext
use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
ladder mpg
```

<table>
<thead>
<tr>
<th>Transformation</th>
<th>Formula</th>
<th>chi2(2)</th>
<th>P(chi2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>cubic</td>
<td>mpg^3</td>
<td>43.59</td>
<td>0.000</td>
</tr>
<tr>
<td>square</td>
<td>mpg^2</td>
<td>27.03</td>
<td>0.000</td>
</tr>
<tr>
<td>identity</td>
<td>mpg</td>
<td>10.95</td>
<td>0.004</td>
</tr>
<tr>
<td>square root</td>
<td>sqrt(mpg)</td>
<td>4.94</td>
<td>0.084</td>
</tr>
<tr>
<td>log</td>
<td>log(mpg)</td>
<td>0.87</td>
<td>0.647</td>
</tr>
<tr>
<td>1/(square root)</td>
<td>1/sqrt(mpg)</td>
<td>0.20</td>
<td>0.905</td>
</tr>
<tr>
<td>inverse</td>
<td>1/mpg</td>
<td>2.36</td>
<td>0.307</td>
</tr>
<tr>
<td>1/square</td>
<td>1/(mpg^2)</td>
<td>11.99</td>
<td>0.002</td>
</tr>
<tr>
<td>1/cubic</td>
<td>1/(mpg^3)</td>
<td>24.30</td>
<td>0.000</td>
</tr>
</tbody>
</table>

If we had typed `ladder mpg, gen(mpgx)`, the variable `mpgx` containing $1/\sqrt{\text{mpg}}$ would have been
automatically generated for us. This is the perfect example of why you should not, in general, specify
the `generate()` option. We also cannot reject the hypothesis that the inverse of `mpg` is normally
distributed and that $1/\text{mpg}$—gallons per mile—has a better interpretation. It is a measure of energy
consumption.
Example 2: gladder

gladder explores the same transforms as ladder but presents results graphically:

```
. gladder mpg, fraction
```

Histograms by transformation

Technical note

```
gladder is useful pedagogically, but be careful when using it for research work, especially with many observations. For instance, consider the following data on the average July temperature in degrees Fahrenheit for 954 U.S. cities:

. use http://www.stata-press.com/data/r14/citytemp
   (City Temperature Data)
. ladder tempjuly
```

<table>
<thead>
<tr>
<th>Transformation</th>
<th>formula</th>
<th>chi2(2)</th>
<th>P(chi2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>cubic</td>
<td>tempjuly^3</td>
<td>47.49</td>
<td>0.000</td>
</tr>
<tr>
<td>square</td>
<td>tempjuly^2</td>
<td>19.70</td>
<td>0.000</td>
</tr>
<tr>
<td>identity</td>
<td>tempjuly</td>
<td>3.83</td>
<td>0.147</td>
</tr>
<tr>
<td>square root</td>
<td>sqrt(tempjuly)</td>
<td>1.83</td>
<td>0.400</td>
</tr>
<tr>
<td>log</td>
<td>log(tempjuly)</td>
<td>5.40</td>
<td>0.067</td>
</tr>
<tr>
<td>1/(square root)</td>
<td>1/sqrt(tempjuly)</td>
<td>13.72</td>
<td>0.001</td>
</tr>
<tr>
<td>inverse</td>
<td>1/tempjuly</td>
<td>26.36</td>
<td>0.000</td>
</tr>
<tr>
<td>1/square</td>
<td>1/(tempjuly^2)</td>
<td>64.43</td>
<td>0.000</td>
</tr>
<tr>
<td>1/cubic</td>
<td>1/(tempjuly^3)</td>
<td>.</td>
<td>0.000</td>
</tr>
</tbody>
</table>

The period in the last line indicates that the $\chi^2$ is very large; see [R] sktest.
From the table, we see that there is certainly a difference in normality between the square and square-root transform. If, however, you can see the difference between the transforms in the diagram below, you have better eyes than we do:

```
. gladder tempjuly, ltitle("") ylabel(none) xlabel(none)
```

<table>
<thead>
<tr>

<th>square</th>
<th>identity</th>
</tr>
</thead>
<tbody>
<tr>
<td>sqrt</td>
<td>log</td>
<td>1/sqrt</td>
</tr>
<tr>
<td>inverse</td>
<td>1/square</td>
<td>1/cubic</td>
</tr>
</tbody>
</table>

Average July temperature

Histograms by transformation

➢ Example 3: qladder

A better graph for seeing normality is the quantile–normal graph, which can be produced by qladder.
This graph shows that for the square transform, the upper tail—and only the upper tail—diverges from what would be expected. This divergence is detected by `sktest` (see [R] `sktest`) as a problem with skewness, as we would learn from using `sktest` to examine `tempjuly` squared and square rooted.
Stored results

`ladder` stores the following in `r()`:

Scalars

- `r(N)` number of observations
- `r(invcube)` $\chi^2$ for inverse-cubic transformation
- `r(P_invcube)` significance level for inverse-cubic transformation
- `r(invsq)` $\chi^2$ for inverse-square transformation
- `r(P_invsq)` significance level for inverse-square transformation
- `r(inv)` $\chi^2$ for inverse transformation
- `r(P_inv)` significance level for inverse transformation
- `r(invsqrt)` $\chi^2$ for inverse-root transformation
- `r(P_invsqrt)` significance level for inverse-root transformation
- `r(log)` $\chi^2$ for log transformation
- `r(P_log)` significance level for log transformation
- `r(sqrt)` $\chi^2$ for square-root transformation
- `r(P_sqrt)` significance level for square-root transformation
- `r(ident)` $\chi^2$ for untransformed data
- `r(P_ident)` significance level for untransformed data
- `r(square)` $\chi^2$ for square transformation
- `r(P_square)` significance level for square transformation
- `r(cube)` $\chi^2$ for cubic transformation
- `r(P_cube)` significance level for cubic transformation

Methods and formulas

For `ladder`, results are as reported by `sktest`; see [R] `sktest`. If `generate()` is specified, the transform with the minimum $\chi^2$ value is chosen.

`gladder` sets the number of bins to $\min(\sqrt{n}, 10 \log_{10} n)$, rounded to the closest integer, where $n$ is the number of unique values of `varname`. See [R] `histogram` for a discussion of the optimal number of bins.

Also see Findley (1990) for a ladder-of-powers variable transformation program that produces one-way graphs with overlaid box plots, in addition to histograms with overlaid normals. Buchner and Findley (1990) discuss ladder-of-powers transformations as one aspect of preliminary data analysis. Also see Hamilton (1992, 18–23) and Hamilton (2013, 129–132).

Acknowledgment

`qladder` was written by Jeroen Weesie of the Department of Sociology at Utrecht University, The Netherlands.

**level — Set default confidence level**

**Description**

`set level` specifies the default confidence level for confidence intervals for all commands that report confidence intervals. The initial value is 95, meaning 95% confidence intervals.

**Syntax**

```
set level # [, permanently]
```

# is any number between 10.00 and 99.99 and may be specified with at most two digits after the decimal point.

**Option**

`permanently` specifies that, in addition to making the change right now, the `level` setting be remembered and become the default setting when you invoke Stata.

**Remarks and examples**

To change the level of confidence intervals reported by a particular command, you need not reset the default confidence level. All commands that report confidence intervals have a `level(#)` option. When you do not specify the option, the confidence intervals are calculated for the default level set by `set level`, or for 95% if you have not reset `set level`.

**Example 1**

We use the `ci means` command to obtain the confidence interval for the mean of `mpg`:

```
. use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
. ci means mpg
```

```
Variable |    Obs  Mean    Std. Err.      [95% Conf. Interval]
---------|--------|------------|-----------------------------|
          |        |            |                            |
          |        |            |                            |

<td>21.2973</td>
<td>.6725511</td>
<td>20.17683  22.41776</td>
</tr>
</tbody>
</table>
```

If we opt for the second alternative, the next time that we fit a model (say, with `regress`), 90% confidence intervals will be reported. If we wanted 95% confidence intervals, we could specify `level(95)` on the estimation command, or we could reset the default by typing `set level 95`.

The current setting of `level()` is stored as the c-class value `c(level)`; see [P] `creturn`.

## Description

This entry provides a quick reference for the size limits in Stata. Note that most of these limits are so high that you will never encounter them.

## Remarks and examples

Remarks are presented under the following headings:

**Maximum size limits**

**Matrix size**

**Determining which flavor of Stata you are running**

### Maximum size limits

(1) For Stata/MP, the maximum number of observations is $281,474,976,710,655$, and for Stata/SE, the maximum number is $2,147,483,647$. In practice, both flavors are limited by memory.

(2) The maximum length of the contents of a macro are fixed in Stata/IC and settable in Stata/SE and Stata/MP. The currently set maximum length is recorded in $c(macrolen)$; type `display c(macrolen)`. The maximum length can be changed with `set maxvar`. If you set `maxvar` to a larger value, the maximum length increases; if you set `maxvar` to a smaller value, the maximum length decreases. The relationship between them is $maximum\_length = 129 \times maxvar + 200$.

(3) In Mata, matrices are limited only by the amount of memory on your computer.
Matrix size

See [R] matsize.

Determining which flavor of Stata you are running

Type

. about

The response will be Stata/MP, Stata/SE, Stata/IC, or Small Stata. Other information is also shown, including your serial number. See [R] about.

Description

`lincom` computes point estimates, standard errors, \( t \) or \( z \) statistics, \( p \)-values, and confidence intervals for linear combinations of coefficients after any estimation command, including survey estimation. Results can optionally be displayed as odds ratios, hazard ratios, incidence-rate ratios, or relative-risk ratios.

Quick start

Point estimate and confidence interval for sum of coefficients of \( x_1 \) and \( x_2 \)

```
lincom x1 + x2
```

As above, but report results as a relative-risk ratio

```
lincom x1 + x2, rrr
```

As above, but use coefficients from second equation of a multiequation model

```
```

Difference between coefficients of first and third level of categorical variable \( a \)

```
lincom 1.a - 3.a
```

Sum of coefficients of \( x_1 \) and \( x_2 \) after a model adjusted for complex survey design

```
lincom x1 + x2
```

Menu

Statistics > Postestimation
lincom — Linear combinations of parameters

Syntax

```
lincom exp [, options ]
```

**options**

<table>
<thead>
<tr>
<th>option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>eform</code></td>
<td>generic label; exp(b)</td>
</tr>
<tr>
<td><code>or</code></td>

<td>relative-risk ratio</td>
</tr>
<tr>
<td><code>level(#)</code></td>
<td>set confidence level; default is level(95)</td>
</tr>
</tbody>
</table>

**display_options**

control column formats

| df(#)     | use t distribution with # degrees of freedom for computing p-values and confidence intervals |

*exp* is any linear combination of coefficients that is a valid syntax for *test*; see [R] test. *exp* must not contain an equal sign.

*df(#) does not appear in the dialog box.

**Options**

`eform`, `or`, `hr`, `shr`, `irr`, and `rrr` all report coefficient estimates as exp(\(\hat{\beta}\)) rather than \(\hat{\beta}\). Standard errors and confidence intervals are similarly transformed. `or` is the default after `logistic`. The only difference in these options is how the output is labeled.

<table>
<thead>
<tr>
<th>Option</th>
<th>Label</th>
<th>Explanation</th>
<th>Example commands</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>eform</code></td>
<td>exp(b)</td>

<tr>
<td><code>rrr</code></td>
<td>RRR</td>
<td>Relative-risk ratio</td>
<td>mlogit</td>
</tr>
</tbody>
</table>

*exp* may not contain any additive constants when you use the `eform`, `or`, `hr`, `irr`, or `rrr` option.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by `set level`; see [U] 20.7 Specifying the width of confidence intervals.

`display_options`: `cformat(\%fmt)`, `pformat(\%fmt)`, and `sformat(\%fmt)`; see [R] estimation options.

The following option is available with `lincom` but is not shown in the dialog box:

`df(#)` specifies that the t distribution with # degrees of freedom be used for computing p-values and confidence intervals. The default is to use e(df_r) degrees of freedom or the standard normal distribution if e(df_r) is missing.
Remarks and examples

Remarks are presented under the following headings:

Using lincom
Odds ratios and incidence-rate ratios
Multiple-equation models

Using lincom

After fitting a model and obtaining estimates for coefficients $\beta_1, \beta_2, \ldots, \beta_k$, you may want to view estimates for linear combinations of the $\beta_i$, such as $\beta_1 - \beta_2$. lincom can display estimates for any linear combination of the form $c_0 + c_1 \beta_1 + c_2 \beta_2 + \cdots + c_k \beta_k$.

lincom works after any estimation command for which test works. Any valid expression for test syntax 1 (see [R] test) is a valid expression for lincom.

lincom is useful for viewing odds ratios, hazard ratios, etc., for one group (that is, one set of covariates) relative to another group (that is, another set of covariates). See the examples below.

Example 1

We perform a linear regression:

```
. use http://www.stata-press.com/data/r14/regress
. regress y x1 x2 x3
```

```
Source | SS df MS Number of obs = 148
-------+--------------------------------------------------
Model | 3259.3561 3 1086.45203 Prob > F = 0.0000
Residual | 1627.56282 144 11.3025196 R-squared = 0.6670
Total | 4886.91892 147 33.2443464 Root MSE = 3.3619

y | Coef. Std. Err. t P>|t| [95% Conf. Interval]
---+--------------------------------------------------
x1 | 1.457113 .107461 1.36 0.177 -.666934 3.581161
x2 | 2.221682 .8610358 2.58 0.011 .5197797 3.923583
x3 | -.006139 .0005543 -11.08 0.000 -.0072345 -.0050435
_cons | 36.10135 4.382693 8.24 0.000 27.43863 44.76407
```

To see the difference of the coefficients of $x_2$ and $x_1$, we type

```
. lincom x2 - x1
( 1) - x1 + x2 = 0
```

```
y | Coef. Std. Err. t P>|t| [95% Conf. Interval]
---+--------------------------------------------------
(1) | .7645682 .9950282 0.77 0.444 -.120218 2.731316
```

The expression can be any linear combination.

```
. lincom 3*x1 + 500*x3
( 1) 3*x1 + 500*x3 = 0
```

```
y | Coef. Std. Err. t P>|t| [95% Conf. Interval]
---+--------------------------------------------------
(1) | 1.301825 3.396624 0.38 0.702 -5.411858 8.015507
```
Nonlinear expressions are not allowed.

```
. lincom x2/x1
not possible with test
r(131);
```

For information about estimating nonlinear expressions, see [R] nlcom.

---

**Technical note**

`lincom` uses the same shorthands for coefficients as does `test` (see [R] `test`). When you type `x1`, for instance, `lincom` knows that you mean the coefficient of `x1`. The formal syntax for referencing this coefficient is actually `_b[x1]`, or alternatively, `_coef[x1]`. So, more formally, in the last example we could have typed

```
. lincom 3*_b[x1] + 500*_b[x3]
(output omitted)
```

---

**Odds ratios and incidence-rate ratios**

After logistic regression, the `or` option can be specified with `lincom` to display odds ratios for any effect. Incidence-rate ratios after commands such as `poisson` can be similarly obtained by specifying the `irr` option.

---

**Example 2**

Consider the low birthweight dataset from *Hosmer, Lemeshow, and Sturdivant* (2013, 24). We fit a logistic regression model of low birthweight (variable `low`) on the following variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
<th>Coding</th>
</tr>
</thead>
<tbody>
<tr>
<td>age</td>
<td>age in years</td>
<td></td>
</tr>
<tr>
<td>race</td>
<td>race</td>
<td>1 if white, 2 if black, 3 if other</td>
</tr>
<tr>
<td>smoke</td>
<td>smoking status</td>
<td>1 if smoker, 0 if nonsmoker</td>
</tr>
<tr>
<td>ht</td>
<td>history of hypertension</td>
<td>1 if yes, 0 if no</td>
</tr>
<tr>
<td>ui</td>
<td>uterine irritability</td>
<td>1 if yes, 0 if no</td>
</tr>
<tr>
<td>lwd</td>
<td>maternal weight before pregnancy</td>
<td>1 if weight &lt; 110 lb., 0 otherwise</td>
</tr>
<tr>
<td>ptd</td>
<td>history of premature labor</td>
<td>1 if yes, 0 if no</td>
</tr>
<tr>
<td>c.age##lwd</td>
<td>age main effects, lwd main effects, and their interaction</td>
<td></td>
</tr>
<tr>
<td>smoke##lwd</td>
<td>smoke main effects, lwd main effects, and their interaction</td>
<td></td>
</tr>
</tbody>
</table>
We first fit a model without the interaction terms by using `logit`.

```
. use http://www.stata-press.com/data/r14/lbw3
  (Hosmer & Lemeshow data)
. logit low age lwd i.race smoke ptd ht ui
Iteration 0:  log likelihood =  -117.336
Iteration 1:  log likelihood =  -99.3982
Iteration 2:  log likelihood = -98.780418
Iteration 3:  log likelihood = -98.777998
Iteration 4:  log likelihood = -98.777998

  Logistic regression                     Number of obs   =      189
                                    LR chi2(8)    =     37.12
                                    Prob > chi2    = 0.0000
  Log likelihood                       Pseudo R2       =  0.1582
                                -2(log likelihood) = 198.78
                                Number of obs   =      189
                                LR chi2(8)      =  37.12
                                Prob > chi2     = 0.0000
                                Log likelihood  = -98.777998
                              Pseudo R2       =  0.1582

                        Coef.     Std. Err.      z    P>|z|     [95% Conf. Interval]
  low   age          -.0464796    .0373888   -1.24   0.214    -.1197603    .0268011
         lwd          .8420615    .4055338    2.08   0.038     .0472299    1.636893
  race  black       1.073456    .5150753    2.08   0.037     .0639273    2.082985
         other       .8153673    .4452979    1.83   0.067    -.0574008    1.688135
         smoke       .8071996    .4044465    2.00   0.046     .0145001    1.599899
         ptd         1.281678    .4621157    2.77   0.006     .3759478    2.187408
         ht         1.435227    .6482699    2.21   0.027     .1646141    2.705813
         ui         .6576256    .4666192    1.41   0.159    -.2569313    1.572182
         _cons       -1.216781   .9556797   -1.27   0.203    -3.089878   .6563179
```

To get the odds ratio for black smokers relative to white nonsmokers (the reference group), we type

```
. lincom 2.race + smoke, or
( 1)  [low]2.race + [low]smoke = 0

                     Odds Ratio  Std. Err.     z    P>|z|      [95% Conf. Interval]
(1)       6.557805    4.744692    2.60   0.009       1.588176    27.07811
```

`lincom` computed $\exp(\beta_{\text{race}} + \beta_{\text{smoke}}) = 6.56$. To see the odds ratio for white smokers relative to black nonsmokers, we type

```
. lincom smoke - 2.race, or
( 1)  - [low]2.race + [low]smoke = 0

                     Odds Ratio  Std. Err.     z    P>|z|      [95% Conf. Interval]
(1)       .7662425     .4430176   -0.46   0.645       .2467334    2.379603
```
Now let's add the interaction terms to the model (Hosmer and Lemeshow 1989, table 4.10). This time, we will use `logistic` rather than `logit`. By default, `logistic` displays odds ratios.

```
.logistic low i.race ht ui ptd c.age##lwd smoke##lwd
```

Logistic regression

```
Number of obs = 189
LR chi2(10) = 42.66
Prob > chi2 = 0.0000
Log likelihood = -96.00616 Pseudo R2 = 0.1818
```

| low  | Odds Ratio | Std. Err. | z     | P>|z|   | [95% Conf. Interval] |
|------|------------|-----------|-------|------|---------------------|

| lwd##c.age 1| 1.15883| .09602   | 1.78  | 0.075| .9851215            |
|      |            |           |       |      | 1.36317             |
| smoke| 3.168096   | 1.452378  | 2.52  | 0.012| 1.289956            |
|      |            |           |       |      | 7.78076             |
| smoker#lwd smoker#1| .2447849| .2003996| -1.72 | 0.086| .0491956            |
|      |            |           |       |      | 1.217988            |
| _cons| .599443    | .6519163  | -0.47 | 0.638| .0711271            |
|      |            |           |       |      | 5.051971            |

Hosmer and Lemeshow (1989, table 4.13) consider the effects of smoking (smoke = 1) and low maternal weight before pregnancy (lwd = 1). The effect of smoking among non–low-weight mothers (lwd = 0) is given by the odds ratio 3.17 for `smoke` in the `logistic` output. The effect of smoking among low-weight mothers is given by

```
.lincom 1.smoke + 1.smoke#1.lwd
( 1) [low]1.smoke + [low]1.smoke#1.lwd = 0
```

```
| low  | Odds Ratio | Std. Err. | z     | P>|z|   | [95% Conf. Interval] |
|------|------------|-----------|-------|------|---------------------|
| (1)  | .7755022   | .574951   | -0.34 | 0.732| .1813465            |
|      |            |           |       |      | 3.316323            |
```

We did not have to specify the `or` option. After `logistic`, `lincom` assumes `or` by default.

The effect of low weight (lwd = 1) is more complicated because we fit an age × lwd interaction. We must specify the age of mothers for the effect. The effect among 30-year-old nonsmokers is given by

```
.lincom 1.lwd + 30*1.lwd#c.age
( 1) [low]1.lwd + 30*[low]1.lwd#c.age = 0
```

```
| low  | Odds Ratio | Std. Err. | z     | P>|z|   | [95% Conf. Interval] |
|------|------------|-----------|-------|------|---------------------|
| (1)  | 14.7669    | 13.5669   | 2.93  | 0.003| 2.439264            |
|      |            |           |       |      | 89.39633            |
lincom computed \( \exp(\beta_{1.lwd} + 30\beta_{agelwd}) = 14.8 \). It may seem odd that we entered it as \( 1.lwd + 30*1.lwd#c.age \), but remember that these terms are just lincom’s (and test’s) shorthands for \( _b[1.lwd] \) and \( _b[1.lwd#c.age] \). We could have typed

```
.lincom _b[1.lwd] + 30*_b[1.lwd#c.age]
( 1) \[low\]1.lwd + 30*[low]1.lwd#c.age = 0
```

| low | Odds Ratio | Std. Err. | z   | P>|z|   | [95% Conf. Interval] |
|-----|------------|-----------|-----|-------|----------------------|
| (1) | 14.7669    | 13.5669   | 2.93| 0.003 | 2.439264             |

### Multiple-equation models

lincom also works with multiple-equation models. The only difference is how you refer to the coefficients. Recall that for multiple-equation models, coefficients are referenced using the syntax

```
[eqno]varname
```

where `eqno` is the equation number or equation name and `varname` is the corresponding variable name for the coefficient; see [U] 13.5 Accessing coefficients and standard errors and [R] test for details.

#### Example 3

Let’s consider example 4 from [R] mlogit (Tarlov et al. 1989; Wells et al. 1989).

```
use http://www.stata-press.com/data/r14/sysdsn1 (Health insurance data)

. mlogit insure age male nonwhite i.site, nolog
```

Multinomial logistic regression  Number of obs = 615
LR chi2(10) = 42.99
Prob > chi2 = 0.0000
Log likelihood = -534.36165  Pseudo R2 = 0.0387

| insure     | Coef.   | Std. Err. | z     | P>|z|   | [95% Conf. Interval] |
|------------|---------|-----------|-------|-------|----------------------|
| (base outcome) |
| Indemnity  |
| Prepaid    |
| age        | -0.11745| 0.061946  | -1.90 | 0.058 | -0.238862            |
| male       | 0.561693| 0.202746  | 2.77  | 0.006 | 0.1643175            |
| nonwhite   | 0.974776| 0.2363213 | 4.12  | 0.000 | 0.5165955            |
| site       |
| 2          | 0.1130359| 0.2101903| 0.54  | 0.591 | -0.298926            |
| 3          | -0.5879879| 0.2279351| -2.58 | 0.010 | -1.034733            |
| _cons      | 0.2697127| 0.3284422| 0.82  | 0.412 | -0.3740222           |
| Uninsure   |
| age        | -0.0077961| 0.0114418| -0.68 | 0.496 | -0.0302217            |
| male       | 0.4518496| 0.3674867| 1.23  | 0.219 | -0.268411            |
| nonwhite   | 0.2170589| 0.4256361| 0.51  | 0.610 | -0.6171725           |
| site       |
| 2          | -1.211563| 0.4705127| -2.57 | 0.010 | -2.133751            |
| 3          | -0.2078123| 0.3662926| -0.57 | 0.570 | -0.9257327           |
| _cons      | -1.286943| 0.5923219| -2.17 | 0.030 | -2.447872            |
To see the estimate of the sum of the coefficient of \textit{male} and the coefficient of \textit{nonwhite} for the Prepaid outcome, we type

\begin{verbatim}
. lincom [Prepaid]male + [Prepaid]nonwhite
   (1) [Prepaid]male + [Prepaid]nonwhite = 0
\end{verbatim}

| insure | Coef.   | Std. Err. | z    | P>|z|  | [95% Conf. Interval] |
|--------|---------|-----------|------|-------|----------------------|
| (1)    | 1.53647 | .3272489  | 4.70 | 0.000 | .8950741             |

To view the estimate as a ratio of relative risks (see \textit{[R] mlogit} for the definition and interpretation), we specify the \texttt{rrr} option.

\begin{verbatim}
. lincom [Prepaid]male + [Prepaid]nonwhite, rrr
   (1) [Prepaid]male + [Prepaid]nonwhite = 0
\end{verbatim}

| insure | RRR     | Std. Err. | z    | P>|z|  | [95% Conf. Interval] |
|--------|---------|-----------|------|-------|----------------------|
| (1)    | 4.648154| 1.521103  | 4.70 | 0.000 | 2.447517             |

\textbf{Stored results}

\texttt{lincom} stores the following in \(r()\):

- Scalars
  - \(r(\text{estimate})\): point estimate
  - \(r(\text{se})\): estimate of standard error
  - \(r(\text{df})\): degrees of freedom

\texttt{[U] 20 Estimation and postestimation commands}
**Description**

`linktest` performs a link test for model specification after any single-equation estimation command, such as `logistic`, `regress`, or `stcox`.

**Quick start**

Specification link test after a single-equation estimation command without options

```
linktest
```

After `tobit` estimated with right-censoring limit at 24

```
linktest, ul(24)
```

After `stcox` estimated with Efron method for tied failures

```
linktest, efron
```

Perform test on full dataset when estimation used a subset of observations

```
linktest if e(sample) < .
```

**Menu**

Statistics > Postestimation
Syntax

\[ \text{linktest} \ [ \text{if} \] \ [ \text{in} \] \ [ \ , \ cmd\_options \] \]

When if and in are not specified, the link test is performed on the same sample as the previous estimation.

Option

\text{cmd\_options} must be the same options specified with the underlying estimation command, except the \text{display\_options} may differ.

Remarks and examples

The form of the link test implemented here is based on an idea of Tukey (1949), which was further described by Pregibon (1980), elaborating on work in his unpublished thesis (Pregibon 1979). See \text{Methods and formulas} below for more details.

\textbf{Example 1}

We want to explain the mileage ratings of cars in our automobile dataset by using the weight, engine displacement, and whether the car is manufactured outside the United States:

\begin{verbatim}
. use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
. regress mpg weight displ foreign
\end{verbatim}

\begin{tabular}{llllll}
\hline
Source & SS & df & MS & Number of obs & = & 74 \\
\hline
Model & 1619.71935 & 3 & 539.906448 & F(3, 70) & = & 45.88 \\
Residual & 823.740114 & 70 & 11.7677159 & Prob > F & = & 0.0000 \\
\hline
Total & 2443.45946 & 73 & 33.4720474 & Adj R-squared & = & 0.6484 \\
\hline
\end{tabular}

\begin{tabular}{llllll}
\hline
& Coef. & Std. Err. & t & P>|t| & [95% Conf. Interval] \\
\hline
weight & -.0067745 & .0011665 & -5.81 & 0.000 & -.0091011 & -.0044479 \\
displacement & .0019286 & .0100701 & 0.19 & 0.849 & -.0181556 & .0220129 \\
foreign & -1.600631 & 1.113648 & -1.44 & 0.155 & -3.821732 & .6204699 \\
_cons & 41.84795 & 2.350704 & 17.80 & 0.000 & 37.15962 & 46.53628 \\
\hline
\end{tabular}

On the basis of the $R^2$, we are reasonably pleased with this model.
If our model really is specified correctly, then if we were to regress \( \text{mpg} \) on the prediction and the prediction squared, the prediction squared would have no explanatory power. This is what \text{linktest} does:

```
. linktest
```

<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>Number of obs = 74</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model</td>
<td>1670.71514</td>
<td>2</td>
<td>835.357572</td>
<td>F(2, 71) = 76.75</td>
</tr>
<tr>
<td>Residual</td>
<td>772.744316</td>
<td>71</td>
<td>10.8837228</td>
<td>Prob &gt; F = 0.0000</td>
</tr>
<tr>
<td>Total</td>
<td>2443.45946</td>
<td>73</td>
<td>33.4720474</td>
<td>R-squared = 0.6748</td>
</tr>
</tbody>
</table>

We find that the prediction squared does have explanatory power, so our specification is not as good as we thought.

Although \text{linktest} is formally a test of the specification of the dependent variable, it is often interpreted as a test that, conditional on the specification, the independent variables are specified incorrectly. We will follow that interpretation and now include weight squared in our model:

```
. regress mpg weight c.weight#c.weight displ foreign
```

<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>Number of obs = 74</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model</td>
<td>1699.02634</td>
<td>4</td>
<td>424.756584</td>

We now pass the link test.

Example 2

Above we followed a standard misinterpretation of the link test—when we discovered a problem, we focused on the explanatory variables of our model. We might consider varying exactly what the link test tests. The link test told us that our dependent variable was misspecified. For those with an engineering background, mpg is indeed a strange measure. It would make more sense to model energy consumption—gallons per mile—in terms of weight and displacement:

```
. gen gpm = 1/mpg
. regress gpm weight displ foreign
```

<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>Number of obs = 74</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model</td>
<td>.009157962</td>
<td>3</td>
<td>.003052654</td>
<td>F(3, 70) = 76.33</td>
</tr>
<tr>
<td>Residual</td>
<td>.002799666</td>
<td>70</td>
<td>.000039995</td>
<td>Prob &gt; F = 0.0000</td>
</tr>
<tr>
<td>Total</td>
<td>.011957628</td>
<td>73</td>
<td>.000163803</td>
<td>Adj R-squared = 0.7558</td>
</tr>
</tbody>
</table>

| gpm    | Coef.     | Std. Err. | t     | P>|t|   | [95% Conf. Interval] |
|--------|-----------|-----------|-------|-------|----------------------|
| weight | .0000144  | 2.15e-06  | 6.72  | 0.000 | .0000102             | .0000187 |

<td>.011957628</td>
<td>73</td>
<td>.000163803</td>
<td>R-squared = 0.7673</td>
</tr>
</tbody>
</table>

```
gpm
```

| Coef. Std. Err. t P>|t| [95% Conf. Interval] |
|-------------------|-------------------|-----------------|-------------------|
| _hat              | .6608413 .515275 1.28 0.204 -3.665877 1.68827 |
| _hatsq            | 3.275857 4.936655 0.66 0.509 -6.567553 13.11927 |
| _cons             | 0.008365 .0130468 0.64 0.523 -.0176496 .0343795 |

Specifying the model in terms of gallons per mile also solves the specification problem and results in a more parsimonious specification.

Example 3

The link test can be used with any single-equation estimation procedure, not solely regression. Let’s turn our problem around and attempt to explain whether a car is manufactured outside the United States by its mileage rating and weight. To save paper, we will specify `logit`’s `nolog` option, which suppresses the iteration log:

```
. logit foreign mpg weight, nolog
```

```
Logistic regression Number of obs = 74
LR chi2(2) = 35.72
Prob > chi2 = 0.0000
Log likelihood = -27.175156 Pseudo R2 = 0.3966
```

<table>
<thead>
<tr>
<th>foreign</th>
<th>Coef. Std. Err. z P&gt;</th>
<th>z</th>
<th>[95% Conf. Interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>-.1685869 .0919175 -1.83 0.067 -.3487418 .011568</td>
<td></td>
<td></td>
</tr>
<tr>
<td>weight</td>
<td>-.0039067 .0010116 -3.86 0.000 -.0058894 -.001924</td>
<td></td>
<td></td>
</tr>
<tr>
<td>_cons</td>
<td>13.70837 4.518709 3.03 0.002 4.851859 22.56487</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When we run `linktest` after `logit`, the result is another logit specification:

```
. linktest, nolog
```

```
Logistic regression Number of obs = 74
LR chi2(2) = 36.83
Prob > chi2 = 0.0000
Log likelihood = -26.615714 Pseudo R2 = 0.3966
```

<table>
<thead>
<tr>
<th>foreign</th>
<th>Coef. Std. Err. z P&gt;</th>
<th>z</th>
<th>[95% Conf. Interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>_hat</td>
<td>.8438531 .2738759 3.08 0.002 .3070661 1.38064</td>
<td></td>
<td></td>
</tr>
<tr>
<td>_hatsq</td>
<td>-.1559115 .1566842 -0.99 0.320 -.4633596 .1515366</td>
<td></td>
<td></td>
</tr>
<tr>
<td>_cons</td>
<td>0.2630557 .4299598 0.61 0.541 -.57965 1.105761</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The link test reveals no problems with our specification.
If there had been a problem, we would have been virtually forced to accept the misinterpretation of the link test—we would have reconsidered our specification of the independent variables. When using logit, we have no control over the specification of the dependent variable other than to change likelihood functions.

We admit to having seen a dataset once for which the link test rejected the logit specification. We did change the likelihood function, refitting the model using probit, and satisfied the link test. Probit has thinner tails than logit. In general, however, you will not be so lucky.

Technical note

You should specify the same options with linktest that you do with the estimation command, although you do not have to follow this advice as literally as we did in the preceding example. logit’s nolog option merely suppresses a part of the output, not what is estimated. We specified nolog both times to save space.

If you are testing a tobit model, you must specify the censoring points just as you do with the tobit command.

If you are not sure which options are important, duplicate exactly what you specified on the estimation command.

If you do not specify if exp or in range with linktest, Stata will by default perform the link test on the same sample as the previous estimation. Suppose that you omitted some data when performing your estimation, but want to calculate the link test on all the data, which you might do if you believe the model is appropriate for all the data. You would type linktest if e(sample) < . to do this.

Stored results

linktest stores the following in r():

Scalars
- r(t) \( t \) statistic on \_hatsq
- r(df) degrees of freedom

linktest is not an estimation command in the sense that it leaves previous estimation results unchanged. For instance, after running a regression and performing the link test, typing regress without arguments after the link test still replays the original regression.

For integrating an estimation command with linktest, linktest assumes that the name of the estimation command is stored in e(cmd) and that the name of the dependent variable is stored in e(depvar). After estimation, it assumes that the number of degrees of freedom for the \( t \) test is given by e(df_m) if the macro is defined.

If the estimation command reports \( z \) statistics instead of \( t \) statistics, linktest will also report \( z \) statistics. The \( z \) statistic, however, is still returned in r(t), and r(df) is set to a missing value.
Methods and formulas

The link test is based on the idea that if a regression or regression-like equation is properly specified, you should be able to find no additional independent variables that are significant except by chance. One kind of specification error is called a link error. In regression, this means that the dependent variable needs a transformation or “link” function to properly relate to the independent variables. The idea of a link test is to add an independent variable to the equation that is especially likely to be significant if there is a link error.

Let
\[ y = f(X\beta) \]
be the model and \( \hat{\beta} \) be the parameter estimates. \texttt{linktest} calculates
\[ \_\text{hat} = X\hat{\beta} \]
and
\[ \_\text{hatsq} = \_\text{hat}^2 \]
The model is then refit with these two variables, and the test is based on the significance of \( \_\text{hatsq} \). This is the form suggested by Pregibon (1979) based on an idea of Tukey (1949). Pregibon (1980) suggests a slightly different method that has come to be known as “Pregibon’s goodness-of-link test”. We prefer the older version because it is universally applicable, straightforward, and a good second-order approximation. It can be applied to any single-equation estimation technique, whereas Pregibon’s more recent tests are estimation-technique specific.

### Description

**lnskew0** creates \( newvar = \ln(\pm \exp - k) \), choosing \( k \) and the sign of \( \exp \) so that the skewness of \( newvar \) is zero.

**bcskew0** creates \( newvar = (\exp^\lambda - 1)/\lambda \), the Box–Cox power transformation (Box and Cox 1964), choosing \( \lambda \) so that the skewness of \( newvar \) is zero. \( \exp \) must be strictly positive.

### Quick start

Generate \( newv1 \), the zero-skewness log transform of continuous variable \( v1 \)

\[
\text{lnskew0 newv1} = v1
\]

As above, but transform ratio of \( v1 \) to \( v2 \)

\[
\text{lnskew0 newv1} = v1/v2
\]

Zero-skewness Box–Cox transform, \( newv2 \), of \( v2 \)

\[
\text{bcskew0 newv2} = v2
\]

As above, and change the value for convergence to 0.0001 from the default 0.001

\[
\text{bcskew0 newv2} = v2, \text{ zero(.0001)}
\]

### Menu

**lnskew0**

Data > Create or change data > Other variable-creation commands > Zero-skewness log transform

**bcskew0**

Data > Create or change data > Other variable-creation commands > Box-Cox transform
Syntax

Zero-skewness log transform

\[ \text{lnskew0} \ newvar = \exp [\text{if}] [\text{in}] [\ , \text{options}] \]

Zero-skewness Box–Cox transform

\[ \text{bcskew0} \ newvar = \exp [\text{if}] [\text{in}] [\ , \text{options}] \]

options Description

<table>
<thead>
<tr>
<th>Main</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{delta(#)}</td>
<td>increment for derivative of skewness function; default is \text{delta(0.02)} for \text{lnskew0} and \text{delta(0.01)} for \text{bcskew0}</td>
</tr>
<tr>
<td>\text{zero(#)}</td>
<td>value for determining convergence; default is \text{zero(0.001)}</td>
</tr>
<tr>
<td>\text{level(#)}</td>
<td>set confidence level; default is \text{level(95)}</td>
</tr>
</tbody>
</table>

Options

delta(#) specifies the increment used for calculating the derivative of the skewness function with respect to \( k \) (\text{lnskew0}) or \( \lambda \) (\text{bcskew0}). The default values are 0.02 for \text{lnskew0} and 0.01 for \text{bcskew0}.

zero(#) specifies a value for skewness to determine convergence that is small enough to be considered zero and is, by default, 0.001.

level(#) specifies the confidence level for the confidence interval for \( k \) (\text{lnskew0}) or \( \lambda \) (\text{bcskew0}). The confidence interval is calculated only if \text{level()} is specified. \# is specified as an integer; 95 means 95% confidence intervals. The \text{level()} option is honored only if the number of observations exceeds 7.

Remarks and examples

Example 1: lnskew0

Using our automobile dataset (see [U] 1.2.2 Example datasets), we want to generate a new variable equal to \( \ln(mpg - k) \) to be approximately normally distributed. \text{mpg} records the miles per gallon for each of our cars. One feature of the normal distribution is that it has skewness 0.

\[
\text{. use http://www.stata-press.com/data/r14/auto} \\
\text{(1978 Automobile Data)} \\
\text{. lnskew0 lnmpg = mpg} \\
\]

<table>
<thead>
<tr>
<th>Transform</th>
<th>k</th>
<th>[95% Conf. Interval]</th>
<th>Skewness</th>
</tr>
</thead>
<tbody>
<tr>
<td>ln(mpg-k)</td>
<td>5.383659</td>
<td>(not calculated)</td>
<td>-7.05e-06</td>
</tr>
</tbody>
</table>
This created the new variable \( \text{lnmpg} = \ln(\text{mpg} - 5.384) \):

```
. describe lnmpg
storage  display  value
variable name   type     format   label      variable label
  lnmpg          float   %9.0g   ln(mpg-5.383659)
```

Because we did not specify the `level()` option, no confidence interval was calculated. At the outset, we could have typed

```
. use http://www.stata-press.com/data/r14/auto, clear
(Automobile Data)
. lnskew0 lnmpg = mpg, level(95)
```

```
Transform         k              [95% Conf. Interval]       Skewness
ln(mpg-k)        5.383659       -17.12339 9.892416        -7.05e-06
```

The confidence interval is calculated under the assumption that \( \ln(\text{mpg} - k) \) really does have a normal distribution. It would be perfectly reasonable to use `lnskew0`, even if we did not believe that the transformed variable would have a normal distribution—if we literally wanted the zero-skewness transform—although, then the confidence interval would be an approximation of unknown quality to the true confidence interval. If we now wanted to test the believability of the confidence interval, we could also test our new variable `lnmpg` by using `swilk` (see `[R] swilk`) with the `lnnormal` option.

**Technical note**

`lnskew0` and `bcskew0` report the resulting skewness of the variable merely to reassure you of the accuracy of its results. In our example above, `lnskew0` found \( k \) such that the resulting skewness was \( -7 \times 10^{-6} \), a number close enough to zero for all practical purposes. If we wanted to make it even smaller, we could specify the `zero()` option. Typing `lnskew0 new=mpg, zero(1e-8)` changes the estimated \( k \) to 5.383552 from 5.383659 and reduces the calculated skewness to \( -2 \times 10^{-11} \).

When you request a confidence interval, `lnskew0` may report the lower confidence interval as `.`., which should be taken as indicating the lower confidence limit \( k_L = -\infty \). (This cannot happen with `bcskew0`.)

As an example, consider a sample of size \( n \) on \( x \) and assume that the skewness of \( x \) is positive, but not significantly so, at the desired significance level—say, 5%. Then no matter how large and negative you make \( k_L \), there is no value extreme enough to make the skewness of \( \ln(x - k_L) \) equal the corresponding percentile (97.5 for a 95% confidence interval) of the distribution of skewness in a normal distribution of the same sample size. You cannot do this because the distribution of \( \ln(x - k_L) \) tends to that of \( x \)—apart from location and scale shift—as \( x \to \infty \). This “problem” never applies to the upper confidence limit, \( k_U \), because the skewness of \( \ln(x - k_U) \) tends to \( -\infty \) as \( k \) tends upward to the minimum value of \( x \).

---

**Example 2: bcskew0**

In example 1, using `lnskew0` with a variable such as `mpg` is probably undesirable. `mpg` has a natural zero, and we are shifting that zero arbitrarily. On the other hand, use of `lnskew0` with a variable such as temperature measured in Fahrenheit or Celsius would be more appropriate, as the zero is indeed arbitrary.
For a variable like mpg, it makes more sense to use the Box–Cox power transform (Box and Cox 1964):

\[ y(\lambda) = \frac{y^\lambda - 1}{\lambda} \]

\( \lambda \) is free to take on any value, but \( y^{(1)} = y - 1 \), \( y^{(0)} = \ln(y) \), and \( y^{(-1)} = 1 - 1/y \).

bcskew0 works like lnskew0:

```
.bcskew0 bcmpg = mpg, level(95)
```

<table>
<thead>
<tr>
<th>Transform</th>
<th>L</th>
<th>[95% Conf. Interval]</th>
<th>Skewness</th>
</tr>
</thead>
<tbody>
<tr>
<td>(mpg^L-1)/L</td>
<td>-.3673283</td>
<td>-1.212752</td>
<td>.4339645</td>
</tr>
</tbody>
</table>

The 95% confidence interval includes \( \lambda = -1 \) (\( \lambda \) is labeled L in the output), which has a rather more pleasing interpretation—gallons per mile—than \( (\text{mpg}^{-0.3673} - 1)/(-0.3673) \). The confidence interval, however, is calculated assuming that the power transformed variable is normally distributed. It makes perfect sense to use bcskew0, even when you do not believe that the transformed variable will be normally distributed, but then the confidence interval is an approximation of unknown quality. If you believe that the transformed data are normally distributed, you can alternatively use boxcox to estimate \( \lambda \); see [R] boxcox.

### Stored results

lnskew0 and bcskew0 store the following in \( r() \):

**Scalars**

- \( r(\text{gamma}) \): \( k \) (lnskew0)
- \( r(\text{lambda}) \): \( \lambda \) (bcskew0)
- \( r(lb) \): lower bound of confidence interval
- \( r(ub) \): upper bound of confidence interval
- \( r(\text{skewness}) \): resulting skewness of transformed variable

### Methods and formulas

Skewness is as calculated by summarize; see [R] summarize. Newton’s method with numeric, uncentered derivatives is used to estimate \( k \) (lnskew0) and \( \lambda \) (bcskew0). For lnskew0, the initial value is chosen so that the minimum of \( x - k \) is 1, and thus \( \ln(x - k) \) is 0. bcskew0 starts with \( \lambda = 1 \).

### Acknowledgment

lnskew0 and bcskew0 were written by Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book *Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model*.

log — Echo copy of session to file

**Description**

`log` and its subcommands tell Stata to open a log file and create a record of what you type and any output that appears in the Results window, to suspend or resume logging, to check logging status, and to close the log file. The default format is Stata Markup and Control Language (SMCL) but can be plain text. You can have up to five SMCL and five text logs open at a time. `cmdlog` and its subcommands are similar to `log` but create a command log recording only what you type and can be only plain text. You can have only one command log open at a time.

`set logtype` and `set linesize` are commands to control system parameters that relate to logs.

**Quick start**

Begin recording your Stata session in `mylog.smcl`

```
log using mylog
```

As above, but use a text format that can be read by a word processor

```
log using mylog, text
```

Save a subset of output to `mylog2.smcl` while `mylog.smcl` is still open

```
log using mylog2, name(mylog2)
```

Close `mylog2.smcl` and keep `mylog.smcl` open

```
log close mylog2
```

Create a do-file from commands typed interactively

```
cmdlog using mydo.do
```

**Menu**

File > Log
Syntax

Report status of log file

log

log query [logname | all]

Open log file

log using filename [, append replace [text | smcl] name(logname)]

Close log

log close [logname | all]

Temporarily suspend logging or resume logging

log {off | on} [logname]

Report status of command log file

cmdlog

Open command log file

cmdlog using filename [, append replace]

Close command log, temporarily suspend logging, or resume logging

cmdlog {close | on | off}

Set default format for logs

set logtype {text | smcl} [, permanently]

Specify screen width

set linesize #

In addition to using the log command, you may access the capabilities of log by selecting File > Log from the menu and choosing one of the options in the list.

Options for use with both log and cmdlog

append specifies that results be appended to an existing file. If the file does not already exist, a new file is created.

replace specifies that filename, if it already exists, be overwritten. When you do not specify either replace or append, the file is assumed to be new. If the specified file already exists, an error message is issued and logging is not started.
Options for use with log

text and smcl specify the format in which the log is to be recorded. The default is complicated to describe but is what you would expect:

If you specify the file as filename.smcl, the default is to write the log in SMCL format (regardless of the value of set logtype).

If you specify the file as filename.log, the default is to write the log in text format (regardless of the value of set logtype).

If you type filename without an extension and specify neither the smcl option nor the text option, the default is to write the file according to the value of set logtype. If you have not set logtype, then the default is SMCL. Also, the filename you specified will be fixed to read filename.smcl if a SMCL log is being created or filename.log if a text log is being created.

If you specify either the text or smcl option, then what you specify determines how the log is written. If filename was specified without an extension, the appropriate extension is added for you.

If you open multiple log files, you may choose a different format for each file.

name(logname) specifies an optional name you may use to refer to the log while it is open. You can start multiple log files, give each a different logname, and then close, temporarily suspend, or resume them each individually. The default logname is <unnamed>.

Option for use with set logtype

permanently specifies that, in addition to making the change right now, the logtype setting be remembered and become the default setting when you invoke Stata.

Remarks and examples

A full log is a file containing what you type and Stata’s output that is shown in the Results window. To begin logging your session, you type log using filename. If filename contains embedded spaces, remember to enclose it in double quotation marks.

When the default log format is SMCL, log will add the extension .smcl if filename is specified without one. If text is specified or the default log type is changed to text, log adds the extension .log.

We recommend using SMCL because it preserves fonts and colors. SMCL logs can be viewed and printed from the Viewer window, as can any text file; see [R] view. Users of console Stata can use translate to produce printable versions of log files. translate also converts SMCL logs to text or other formats, such as PostScript or PDF; see [R] translate.

When you open a full log, the default is to show the name of the file and a time and date stamp:

    . log using myfile

    name: <unnamed>
    log: C:\data\proj1\myfile.smcl
    log type: smcl
    opened on: 12 Jan 2015, 12:28:23
The above information will appear in the log. If you do not want this information to appear, precede the command by quietly:

```
. quietly log using myfile
```

quietly will not suppress any error messages or anything else you need to know.

Similarly, when you close a full log, the default is to show the full information,

```
. log close
    name: <unnamed>
    log: C:\data\proj1\myfile.smcl
    log type: smcl
    closed on: 12 Jan 2015, 12:32:41
```

and that information will also appear in the log. If you want to suppress that, type quietly log close.

If you do not specify name(logname), Stata will use the name <unnamed>, as shown above. However, you can start multiple log files by specifying the name() option with each new log using command. To control a specific log, type, for example, log close logname; to close all log files at one time, type log close _all.

Stata also lets you log only your commands using cmdlog. Command logs are always text files, which makes them easy to convert to do-files. The default extension is .txt instead of .do to keep you from accidentally overwriting your important do-files. However, cmdlog will allow you to specify .do as the extension of filename.

You can have only one command log open at a time. However, you can have full logs open while logging your commands. Moreover, the text file you create for your command log does not count against the limit of five text logs.

set logtype specifies the default format in which full logs are to be recorded. Initially, full logs are recorded in SMCL format.

set linesize specifies the maximum width, in characters, of Stata output. Most commands in Stata do not respect linesize, because it is not important for most commands. Most users never need to set linesize, because it will automatically be reset if you resize your Results window. This is also why there is no permanently option allowed with set linesize. set linesize is for use with commands such as list and display and is typically used by programmers who wish the output of those commands to be wider or narrower than the current width of the Results window.

### Stored results

log and cmdlog store the following in r():

**Macros**

- r(name) \( \rightarrow \) logname
- r(filename) \( \rightarrow \) name of file
- r(status) \( \rightarrow \) on or off
- r(type) \( \rightarrow \) smcl or text

log query _all stores the following in r():

** Scalars**

- r(numlogs) \( \rightarrow \) number of open log files
For each open log file, \texttt{log query \_all} also stores

\begin{itemize}
\item \texttt{r(name\#)} \hspace{1cm} \textit{logname}
\item \texttt{r(filename\#)} \hspace{1cm} \text{name of file}
\item \texttt{r(status\#)} \hspace{1cm} \text{on or off}
\item \texttt{r(type\#)} \hspace{1cm} \text{smcl or text}
\end{itemize}

where \# varies between 1 and the value of \texttt{r(numlogs)}. Be aware that \# will not necessarily represent the order in which the log files were first opened, nor will it necessarily remain constant for a given log file upon multiple calls to \texttt{log query}.

**Description**

logistic fits a logistic regression model of *depvar* on *indepvars*, where *depvar* is a 0/1 variable (or, more precisely, a 0/non-0 variable). Without arguments, logistic redisplay the last logistic estimates. logistic displays estimates as odds ratios; to view coefficients, type logit after running logistic. To obtain odds ratios for any covariate pattern relative to another, see [R] lincom.

**Quick start**

Report odds ratios from logistic regression of y on x1 and x2

```
logistic y x1 x2
```

Add indicators for values of categorical variable a

```
logistic y x1 x2 i.a
```

As above, and apply frequency weights defined by wvar

```
logistic y x1 x2 i.a [fweight=wvar]
```

Show base level of a

```
logistic y x1 x2 i.a, baselevels
```
Syntax

```
logistic  depvar  indepvars  [if]  [in]  [weight]  [,  options]
```

`indepvars` may contain factor variables; see [U] 11.4.3 Factor variables.
`depvar` and `indepvars` may contain time-series operators; see [U] 11.4.4 Time-series varlists.
`bootstrap`, `by`, `fp`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 Prefix commands.
`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] mi estimate.
Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.
`vce()` and weights are not allowed with the `svy` prefix; see [SVY] svy.
`fweight`, `iweight`, and `pweight` are allowed; see [U] 11.1.6 weight.
`coeflegend` does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

**Options**

```
Model
noconstant, offset(varname), constraints(constraints), collinear; see [R] estimation options.
```

`asis` forces retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] probit.
SE/Robust

\texttt{vce(vcetype)} specifies the type of standard error reported, which includes types that are derived from asymptotic theory (\texttt{oim}), that are robust to some kinds of misspecification (\texttt{robust}), that allow for intragroup correlation (\texttt{cluster clustvar}), and that use bootstrap or jackknife methods (\texttt{bootstrap}, \texttt{jackknife}); see \cite{R vce option}. Reporting level(#); see \cite{R estimation options}. \texttt{coef} causes \texttt{logistic} to report the estimated coefficients rather than the odds ratios (exponentiated coefficients). \texttt{coef} may be specified when the model is fit or may be used later to redisplay results. \texttt{coef} affects only how results are displayed and not how they are estimated. \texttt{nocsreport}; see \cite{R estimation options}. display_options: \texttt{noci}, \texttt{nopvalues}, \texttt{noomitted}, \texttt{vsquish}, \texttt{noemptycells}, \texttt{baselevels}, \texttt{allbaselevels}, \texttt{nofvlabel}, \texttt{fvwrap(#)}, \texttt{fvwrapon(style)}, \texttt{cformat(\%fmt)}, \texttt{pformat(\%fmt)}, \texttt{sformat(\%fmt)}, and \texttt{nolstretch}; see \cite{R estimation options}. Maximization \texttt{maximize} options: \texttt{difficult}, \texttt{technique(algorithm_spec)}, \texttt{iterate(#)}, \texttt{[no]log}, \texttt{trace}, \texttt{gradient}, \texttt{showstep}, \texttt{hessian}, \texttt{showtolerance}, \texttt{tolerance(#)}, \texttt{ltolerance(#)}, \texttt{nrtolerance(#)}, \texttt{nonrtolerance}, and from\texttt{(init_specs)}; see \cite{R maximize}. These options are seldom used. The following option is available with \texttt{logistic} but is not shown in the dialog box: \texttt{coeflegend}; see \cite{R estimation options}. Remarks and examples Remarks are presented under the following headings:

\texttt{logistic and logit}
\texttt{Robust estimate of variance}
\texttt{Video examples}

\texttt{logistic and logit}

\texttt{logistic} provides an alternative and preferred way to fit maximum-likelihood logit models, the other choice being \texttt{logit} \cite{R logit}. First, let’s dispose of some confusing terminology. We use the words \texttt{logit} and \texttt{logistic} to mean the same thing: maximum likelihood estimation. To some, one or the other of these words connotes transforming the dependent variable and using weighted least squares to fit the model, but that is not how we use either word here. Thus the \texttt{logit} and \texttt{logistic} commands produce the same results.

The \texttt{logistic} command is generally preferred to the \texttt{logit} command because \texttt{logistic} presents the estimates in terms of odds ratios rather than coefficients. To some people, this may seem disadvantageous, but you can type \texttt{logit} without arguments after \texttt{logistic} to see the underlying coefficients. You should be cautious when interpreting the odds ratio of the constant term. Usually, this odds ratio represents the baseline odds of the model when all predictor variables are set to zero. However, you must verify that a zero value for all predictor variables in the model actually makes sense before continuing with this interpretation.
Nevertheless, \texttt{[R] logit} is still worth reading because \texttt{logistic} shares the same features as \texttt{logit}, including omitting variables due to collinearity or one-way causation.

For an introduction to logistic regression, see Lemeshow and Hosmer (2005), Pagano and Gauvreau (2000, 470–487), or Pampel (2000); for a complete but nonmathematical treatment, see Kleinbaum and Klein (2010); and for a thorough discussion, see Hosmer, Lemeshow, and Sturdivant (2013). See Gould (2000) for a discussion of the interpretation of logistic regression. See Dupont (2009) or Hilbe (2009) for a discussion of logistic regression with examples using Stata. For a discussion using Stata with an emphasis on model specification, see Vittinghoff et al. (2012).

Stata has a variety of commands for performing estimation when the dependent variable is dichotomous or polytomous. See Long and Freese (2014) for a book devoted to fitting these models with Stata. Below is a list of some estimation commands that may be of interest. See \texttt{help estimation commands} for a complete list of all of Stata’s estimation commands.

```

Sorted by:

We want to investigate the causes of low birthweight. Here `race` is a categorical variable indicating whether a person is white (`race = 1`), black (`race = 2`), or some other race (`race = 3`). We want indicator (dummy) variables for `race` included in the regression, so we will use factor variables.

```stata
.logistic low age lwt i.race smoke ptl ui
Logistic regression Number of obs = 189
LR chi2(8) = 33.22
Prob > chi2 = 0.0001
Log likelihood = -100.724 Pseudo R2 = 0.1416

|        | Odds Ratio | Std. Err. | z      | P>|z| [95% Conf. Interval] |
|--------|------------|-----------|--------|--------|-----------------------|
| low    |            |           |        |        |                       |
| age    | .9732636   | .0354759  | -0.74  | 0.457  | .9061578 1.046339    |

| race   |            |           |        |        |                       |
| black  | 3.534767   | 1.860737  | 2.40   | 0.016  | 1.259736 9.918406    |
| other  | 2.368079   | 1.039949  | 1.96   | 0.050  | 1.001356 5.600207    |
| smoke  |            |           |        |        |                       |
| ptl    | 1.719161   | .5952579  | 1.56   | 0.118  | .8721455 3.388787    |
| ht     | 6.249602   | 4.322408  | 2.65   | 0.008  | 1.611152 24.24199    |
| ui     | 2.1351     | .9808153  | 1.65   | 0.099  | .8677528 5.2534      |
| _cons  | 1.586014   | 1.910496  | 0.38   | 0.702  | .1496092 16.8134     |
```

The odds ratios are for a one-unit change in the variable. If we wanted the odds ratio for `age` to be in terms of 4-year intervals, we would type
. gen age4 = age/4
. logistic low age4 lwt i.race smoke ptl ht ui
(output omitted)

After logistic, we can type logit to see the model in terms of coefficients and standard errors:

. logit

Logistic regression
Number of obs = 189
LR chi2(8) = 33.22
Prob > chi2 = 0.0001
Log likelihood = -100.724  Pseudo R2 = 0.1416

|   | Coef. | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|---|-------|-----------|------|------|----------------------|
| age4 | -.1084012 | .1458017 | -0.74 | 0.457 | -.3941673 - .1773649 |
| lwt  | -.0151508 | .0069259 | -2.19 | 0.029 | -.0287263 - .0015763 |
| race |           |           |      |      |                      |
| black | 1.262647  | .5264101 | 2.40 | 0.016 | .2309024 2.294392  |
| other | .8620792  | .4391532 | 1.96 | 0.050 | .0013548 1.722804  |
| smoke|           |           |      |      |                      |
| ptl  | .5418366  | .346249  | 1.56 | 0.118 | -.136799 1.220472  |
| ht   | 1.832518  | .6916292 | 2.65 | 0.008 | .4769494 3.188086  |
| ui   | .7585135  | .4593768 | 1.65 | 0.099 | -.1418484 1.658875  |
| _cons | .4612239  | 1.20459  | 0.38 | 0.702 | -1.899729 2.822176  |

If we wanted to see the logistic output again, we would type logistic without arguments.

Example 2

We can specify the confidence interval for the odds ratios with the level() option, and we can do this either at estimation time or when replaying the model. For instance, to see our first model in example 1 with narrower, 90% confidence intervals, we might type

. logistic, level(90)

Logistic regression
Number of obs = 189
LR chi2(8) = 33.22
Prob > chi2 = 0.0001
Log likelihood = -100.724  Pseudo R2 = 0.1416

|   | Odds Ratio | Std. Err. | z    | P>|z| | [90% Conf. Interval] |
|---|------------|-----------|------|------|---------------------|
| age4 | .8972675  | .1308231 | -0.74 | 0.457 | .7059409 1.140448  |
| lwt  | .9849634  | .0068217 | -2.19 | 0.029 | .9738063  .9962483 |
| race |           |           |      |      |                      |

</tbody>
</table>
\end{verbatim}

Also you can specify \texttt{vce(cluster clustvar)} and then, within cluster, relax the assumption of independence. To illustrate this, we have made some fictional additions to the low-birthweight data.

Say that these data are not a random sample of mothers but instead are a random sample of mothers from a random sample of hospitals. In fact, that may be true—we do not know the history of these data.

Hospitals specialize, and it would not be too incorrect to say that some hospitals specialize in more difficult cases. We are going to show two extremes. In one, all hospitals are alike, but we are going to estimate under the possibility that they might differ. In the other, hospitals are strikingly different. In both cases, we assume that patients are drawn from 20 hospitals.

In both examples, we will fit the same model, and we will type the same command to fit it. Below are the same data we have been using but with a new variable, \texttt{hospid}, that identifies from which of the 20 hospitals each patient was drawn (and which we have made up):

. use http://www.stata-press.com/data/r14/hospid1, clear
. logistic low age lwt i.race smoke ptl ht ui, vce(cluster hospid)

Logistic regression
Number of obs = 189
Wald chi2(8) = 49.67
Prob > chi2 = 0.0000
Log pseudolikelihood = -100.724 Pseudo R2 = 0.1416
(Std. Err. adjusted for 20 clusters in hospid)

<table>
<thead>
<tr>
<th>Robust</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Odds Ratio</td>
<td>Std. Err.</td>
<td>z</td>
</tr>
<tr>
<td>age</td>
<td>.9732636</td>
<td>.0397476</td>
<td>-0.66</td>
</tr>
<tr>

</tr>
</tbody>
</table>

The standard errors are similar to the standard errors we have previously obtained, whether we used the robust or conventional estimators. In this example, we invented the hospital IDs randomly.

Here are the results of the estimation with the same data but with a different set of hospital IDs:

. use http://www.stata-press.com/data/r14/hospid2
. logistic low age lwt i.race smoke ptl ht ui, vce(cluster hospid)

Logistic regression
Number of obs = 189
Wald chi2(8) = 7.19
Prob > chi2 = 0.5167
Log pseudolikelihood = -100.724 Pseudo R2 = 0.1416
(Std. Err. adjusted for 20 clusters in hospid)

Note the strikingly larger standard errors. What happened? In these data, women most likely to have low-birthweight babies are sent to certain hospitals, and the decision on likeliness is based not just on age, smoking history, etc., but on other things that doctors can see but that are not recorded in our data. Thus merely because a woman is at one of the centers identifies her to be more likely to have a low-birthweight baby.

Logistic regression, part 1: Binary predictors
Logistic regression, part 2: Continuous predictors
Logistic regression, part 3: Factor variables

Stored results

logistic stores the following in e():

Scalars

e(N) number of observations

e(N_cds) number of completely determined successes

e(N_cdf) number of completely determined failures

e(k) number of parameters

e(k_eq) number of equations in e(b)

e(k_eq_model) number of equations in overall model test

e(k_dv) number of dependent variables

e(df_m) model degrees of freedom

e(r2_p) pseudo-R-squared

Scalars (continued)
e(ll) log likelihood

e(ll_0) log likelihood, constant-only model

e(N_clust) number of clusters

e(chi2) $\chi^2$ significance of model test

e(p) significance of model test

e(rank) rank of e(V)

e(ic) number of iterations

e(rc) return code

e(converged) 1 if converged, 0 otherwise

Macros

e(cmd) logistic

e(cmdline) command as typed

e(depvar) name of dependent variable

e(wtype) weight type

e(wexp) weight expression

eタイトル) title in estimation output

e(clustvar) name of cluster variable

e(offset) linear offset variable

e(chi2type) Wald or LR: type of model $\chi^2$ test

e(vcsetype) vcetype specified in vce()

e(vctype) title used to label Std. Err.

e(opt) type of optimization

e(technique) maximization technique

e(ml_method) type of ml method

e(user) name of likelihood-evaluator program

e(properties) b V

e(estat_cmd) program used to implement estat

e(predict) program used to implement predict

e(marginsnotok) predictions disallowed by margins

e(asbalanced) factor variables fvset as asbalanced

e(asobserved) factor variables fvset as asobserved
Methods and formulas

Define $x_j$ as the (row) vector of independent variables, augmented by 1, and $b$ as the corresponding estimated parameter (column) vector. The logistic regression model is fit by \texttt{logit}; see \texttt{[R logit]} for details of estimation.

The odds ratio corresponding to the $i$th coefficient is $\psi_i = \exp(b_i)$. The standard error of the odds ratio is $s_i^\psi = s_i^b$, where $s_i^b$ is the standard error of $b_i$ estimated by \texttt{logit}.

Define $I_j = x_jb$ as the predicted index of the $j$th observation. The predicted probability of a positive outcome is

$$p_j = \frac{\exp(I_j)}{1 + \exp(I_j)}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See \texttt{[P] _robust}, particularly \texttt{Maximum likelihood estimators} and \texttt{Methods and formulas}.

\texttt{logistic} also supports estimation with survey data. For details on VCEs with survey data, see \texttt{[SVY] variance estimation}.

Postestimation commands

The following postestimation commands are of special interest after `logistic`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>estat classification</code></td>
<td>report various summary statistics, including the classification table</td>
</tr>
<tr>
<td><code>estat gof</code></td>
<td>Pearson or Hosmer–Lemeshow goodness-of-fit test</td>
</tr>
<tr>
<td><code>lroc</code></td>
<td>compute area under ROC curve and graph the curve</td>
</tr>
<tr>
<td><code>lsens</code></td>
<td>graph sensitivity and specificity versus probability cutoff</td>
</tr>
</tbody>
</table>

These commands are not appropriate after the `svy` prefix.

The following standard postestimation commands are also available:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>contrast</code></td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td><code>estat ic</code></td>
<td>Akaike’s and Schwarz’s Bayesian information criteria (AIC and BIC)</td>
</tr>
<tr>
<td><code>estat summarize</code></td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td><code>estat vce</code></td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td><code>estat (svy)</code></td>
<td>postestimation statistics for survey data</td>
</tr>
<tr>
<td><code>estimates</code></td>
<td>cataloging estimation results</td>
</tr>
<tr>
<td><code>forecast</code></td>
<td>dynamic forecasts and simulations</td>
</tr>
<tr>
<td><code>hausman</code></td>
<td>Hausman’s specification test</td>
</tr>
<tr>
<td><code>lincom</code></td>
<td>point estimates, standard errors, testing, and inference for linear combinations of coefficients</td>
</tr>
<tr>
<td><code>linktest</code></td>
<td>link test for model specification</td>
</tr>
<tr>
<td><code>lrtest</code></td>
<td>likelihood-ratio test</td>
</tr>
<tr>
<td><code>margins</code></td>
<td>marginal means, predictive margins, marginal effects, and average marginal effects</td>
</tr>
<tr>
<td><code>marginsplot</code></td>
<td>graph the results from margins (profile plots, interaction plots, etc.)</td>
</tr>
<tr>
<td><code>nlcom</code></td>
<td>point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients</td>
</tr>
<tr>
<td><code>predict</code></td>
<td>predictions, residuals, influence statistics, and other diagnostic measures</td>
</tr>
<tr>
<td><code>predictnl</code></td>
<td>point estimates, standard errors, testing, and inference for generalized predictions</td>
</tr>
<tr>
<td><code>pwcompare</code></td>
<td>pairwise comparisons of estimates</td>
</tr>
<tr>
<td><code>suest</code></td>
<td>seemingly unrelated estimation</td>
</tr>
<tr>
<td><code>test</code></td>
<td>Wald tests of simple and composite linear hypotheses</td>
</tr>
<tr>
<td><code>testnl</code></td>
<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.
predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, standard errors, influence statistics, deviance residuals, leverages, sequential numbers, Pearson residuals, and equation-level scores.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , statistic nooffset rules asif ]
```

<table>

<td>score</td>
<td>first derivative of the log likelihood with respect to $x_j \beta$</td>
</tr>
</tbody>
</table>

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample)` ... if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

pr, xb, stdp, and score are the only options allowed with svy estimation results.

Options for predict

- `pr`, the default, calculates the probability of a positive outcome.
- `xb` calculates the linear prediction.
- `stdp` calculates the standard error of the linear prediction.
- `dbeta` calculates the Pregibon (1981) $\Delta \hat{\beta}$ influence statistic, a standardized measure of the difference in the coefficient vector that is due to deletion of the observation along with all others that share the same covariate pattern. In Hosmer, Lemeshow, and Sturdivant (2013, 154–155) jargon, this statistic is $M$-asymptotic; that is, it is adjusted for the number of observations that share the same covariate pattern.
deviance calculates the deviance residual.

dx2 calculates the Hosmer, Lemeshow, and Sturdivant (2013, 191) $\Delta \chi^2$ influence statistic, reflecting the decrease in the Pearson $\chi^2$ that is due to deletion of the observation and all others that share the same covariate pattern.

ddeviance calculates the Hosmer, Lemeshow, and Sturdivant (2013, 191) $\Delta D$ influence statistic, which is the change in the deviance residual that is due to deletion of the observation and all others that share the same covariate pattern.

hat calculates the Pregibon (1981) leverage or the diagonal elements of the hat matrix adjusted for the number of observations that share the same covariate pattern.

number numbers the covariate patterns—observations with the same covariate pattern have the same number. Observations not used in estimation have number set to missing. The first covariate pattern is numbered 1, the second 2, and so on.

residuals calculates the Pearson residual as given by Hosmer, Lemeshow, and Sturdivant (2013, 155) and adjusted for the number of observations that share the same covariate pattern.

rstandard calculates the standardized Pearson residual as given by Hosmer, Lemeshow, and Sturdivant (2013, 191) and adjusted for the number of observations that share the same covariate pattern.

score calculates the equation-level score, $\partial \ln L / \partial (x_j \beta)$.

Options

nooffset is relevant only if you specified offset(varname) for logistic. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $x_j b$ rather than as $x_j b + \text{offset}_j$.

rules requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations. See example 1 in [R] logit postestimation.

asif requests that Stata ignore the rules and the exclusion criteria and calculate predictions for all observations possible by using the estimated parameter from the model. See example 1 in [R] logit postestimation.
margins

Description for margins

margins estimates margins of response for probabilities and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [ predict(statistic ...) ... ] [ options ]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>probability of a positive outcome; the default</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>

<td>not allowed with margins</td>
</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than \( e(b) \).

For the full syntax, see [R] margins.

Remarks and examples

predict is used after logistic to obtain predicted probabilities, residuals, and influence statistics for the estimation sample. The suggested diagnostic graphs below are from Hosmer, Lemeshow, and Sturdivant (2013), where they are more elaborately explained. Also see Collett (2003, 129–168) for a thorough discussion of model checking.
Remarks are presented under the following headings:

predict without options
predict with the xb and stdp options
predict with the residuals option
predict with the number option
predict with the deviance option
predict with the rstandard option
predict with the hat option
predict with the dx2 option
predict with the ddeviance option
predict with the dbeta option

predict without options

Typing `predict newvar` after estimation calculates the predicted probability of a positive outcome.

In example 1 of [R] logistic, we ran the model `logistic low age lwt i.race smoke ptl ht ui`. We obtain the predicted probabilities of a positive outcome by typing:

```
. use http://www.stata-press.com/data/r14/lbw
(Hosmer & Lemeshow data)
. logistic low age lwt i.race smoke ptl ht ui
(output omitted)
. predict p (option `pr` assumed; Pr(low))
. summarize p low
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>p</td>
<td>189</td>
<td>.3121693</td>
<td>.1913915</td>
<td>.0272559</td>
<td>.8391283</td>
</tr>
<tr>
<td>low</td>
<td>189</td>
<td>.3121693</td>
<td>.4646093</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

predict with the xb and stdp options

`predict` with the `xb` option calculates the linear combination $x_j b$, where $x_j$ are the independent variables in the $j$th observation and $b$ is the estimated parameter vector. This is sometimes known as the index function because the cumulative distribution function indexed at this value is the probability of a positive outcome.

With the `stdp` option, `predict` calculates the standard error of the prediction, which is not adjusted for replicated covariate patterns in the data. The influence statistics described below are adjusted for replicated covariate patterns in the data.

predict with the residuals option

`predict` can calculate more than predicted probabilities. The Pearson residual is defined as the square root of the contribution of the covariate pattern to the Pearson $\chi^2$ goodness-of-fit statistic, signed according to whether the observed number of positive responses within the covariate pattern is less than or greater than expected. For instance,
. predict r, residuals
. summarize r, detail

<table>
<thead>
<tr>
<th>Percentiles</th>
<th>Smallest</th>
</tr>
</thead>
<tbody>
<tr>
<td>1%</td>
<td>-1.750923 -2.283885</td>
</tr>
<tr>
<td>5%</td>
<td>-1.129907 -1.750923</td>
</tr>
<tr>
<td>10%</td>
<td>-.9581174 -1.636279</td>
</tr>
<tr>
<td>25%</td>
<td>-.6545911 -1.636279</td>
</tr>
<tr>
<td>50%</td>
<td>-.3806923 Mean -.0242299</td>
</tr>
<tr>
<td>75%</td>
<td>.8162894 2.23879</td>
</tr>
<tr>
<td>90%</td>
<td>1.510355 2.317558 Variance .9941981</td>

</tbody>
</table>

**predict with the number option**

Covariate patterns play an important role in logistic regression. Two observations are said to share the same covariate pattern if the independent variables for the two observations are identical. Although we might think of having individual observations, the statistical information in the sample can be summarized by the covariate patterns, the number of observations with that covariate pattern, and the number of positive outcomes within the pattern. Depending on the model, the number of covariate patterns can approach or be equal to the number of observations, or it can be considerably less.

Stata calculates all the residual and diagnostic statistics in terms of covariate patterns, not observations. That is, all observations with the same covariate pattern are given the same residual and diagnostic statistics. Hosmer, Lemeshow, and Sturdivant (2013, 154–155) argue that such “M-asymptotic” statistics are more useful than “N-asymptotic” statistics.

To understand the difference, think of an observed positive outcome with predicted probability of 0.8. Taking the observation in isolation, the residual must be positive—we expected 0.8 positive responses and observed 1. This may indeed be the correct residual, but not necessarily. Under the M-asymptotic definition, we ask how many successes we observed across all observations with this covariate pattern. If that number were, say, six, and there were a total of 10 observations with this covariate pattern, then the residual is negative for the covariate pattern—we expected eight positive outcomes but observed six. predict makes this kind of calculation and then attaches the same residual to all observations in the covariate pattern.
Occasionally, you might want to find all observations sharing a covariate pattern. `number` allows you to do this:

```plaintext
. predict pattern, number  
. summarize pattern
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>pattern</td>
<td>189</td>
<td>89.2328</td>
<td>53.16573</td>
<td>1</td>
<td>182</td>
</tr>
</tbody>
</table>

We previously fit the model `logistic low age lwt i.race smoke ptl ht ui` over 189 observations. There are 182 covariate patterns in our data.

**predict with the deviance option**

The deviance residual is defined as the square root of the contribution to the likelihood-ratio test statistic of a saturated model versus the fitted model. It has slightly different properties from the Pearson residual (see Hosmer, Lemeshow, and Sturdivant [2013, 155–157]):

```plaintext
. predict d, deviance  
. summarize d, detail
```

<table>
<thead>
<tr>
<th>Percentiles</th>
<th>Smallest</th>

<td>.9970949</td>
<td>-2.283885</td>
<td>3.126763</td>
</tr>
<tr>
<td>189</td>
<td>-.0279135</td>
<td>1.026406</td>
<td>-2.4478</td>
<td>3.149081</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>r</th>
<th>rs</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0000</td>
<td>0.9998</td>
</tr>
</tbody>
</table>

**predict with the rstandard option**

Pearson residuals do not have a standard deviation equal to 1. `rstandard` generates Pearson residuals normalized to have an expected standard deviation equal to 1.

```plaintext
. predict rs, rstandard  
. summarize r rs
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>

Remember that we previously created `r` containing the (unstandardized) Pearson residuals. In these data, whether we use standardized or unstandardized residuals does not matter much.
**predict with the hat option**

Hat calculates the leverage of a covariate pattern—a scaled measure of distance in terms of the independent variables. Large values indicate covariate patterns far from the average covariate pattern that can have a large effect on the fitted model even if the corresponding residual is small. Consider the following graph:

\[
\texttt{. predict h, hat} \\
\texttt{. scatter h r, xline(0)}
\]

The points to the left of the vertical line are observed negative outcomes; here our data contain almost as many covariate patterns as observations, so most covariate patterns are unique. In such unique patterns, we observe either 0 or 1 success and expect \( p \), thus forcing the sign of the residual. If we had fewer covariate patterns—if we did not have continuous variables in our model—there would be no such interpretation, and we would not have drawn the vertical line at 0.

Points on the left and right edges of the graph represent large residuals—covariate patterns that are not fit well by our model. Points at the top of our graph represent high leverage patterns. When analyzing the influence of observations on the model, we are most interested in patterns with high leverage and small residuals—patterns that might otherwise escape our attention.

**predict with the dx2 option**

There are many ways to measure influence, and hat is one example. dx2 measures the decrease in the Pearson \( \chi^2 \) goodness-of-fit statistic that would be caused by deleting an observation (and all others sharing the covariate pattern):
Paraphrasing Hosmer, Lemeshow, and Sturdivant (2013, 195–197), the points going from the top left to the bottom right correspond to covariate patterns with the number of positive outcomes equal to the number in the group; the points on the other curve correspond to 0 positive outcomes. In our data, most of the covariate patterns are unique, so the points tend to lie along one or the other curves; the points that are off the curves correspond to the few repeated covariate patterns in our data in which all the outcomes are not the same.

We examine this graph for large values of \( dx^2 \)—there are two at the top left.

**predict with the ddeviance option**

Another measure of influence is the change in the deviance residuals due to deletion of a covariate pattern:

```
predict dd, ddeviance
```

As with \( dx^2 \), we typically graph \( ddeviance \) against the probability of a positive outcome. We direct you to Hosmer, Lemeshow, and Sturdivant (2013, 195) for an example and for the interpretation of this graph.
One of the more direct measures of influence of interest to model fitters is the Pregibon (1981) \texttt{dbeta} measure, a measure of the change in the coefficient vector that would be caused by deleting an observation (and all others sharing the covariate pattern):

\begin{verbatim}
. predict db, dbeta
. scatter db p
\end{verbatim}

One observation has a large effect on the estimated coefficients. We can easily find this point:

\begin{verbatim}
. sort db
. list in 1
\end{verbatim}

\begin{verbatim}
<table>
<thead>
<tr>
<th>id</th>
<th>low</th>
<th>age</th>
<th>lwt</th>
<th>race</th>
<th>smoke</th>
<th>ptl</th>
<th>ht</th>
<th>ui</th>
<th>ftv</th>

<td>db</td>
<td>.8909163</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
\end{verbatim}
Hosmer, Lemeshow, and Sturdivant (2013, 196) suggest a graph that combines two of the influence measures:

```
. scatter dx2 p [aw=db], title("Symbol size proportional to dBeta") mcolor(none)
```

We can easily spot the most influential points by the `dbeta` and `dx2` measures.

### Methods and formulas

Let $j$ index observations. Define $M_j$ for each observation as the total number of observations sharing $j$’s covariate pattern. Define $Y_j$ as the total number of positive responses among observations sharing $j$’s covariate pattern.

The Pearson residual for the $j$th observation is defined as

$$r_j = \frac{Y_j - M_j p_j}{\sqrt{M_j p_j (1 - p_j)}}$$

For $M_j > 1$, the deviance residual $d_j$ is defined as

$$d_j = \pm \left(2 \left[ Y_j \ln \left( \frac{Y_j}{M_j p_j} \right) + (M_j - Y_j) \ln \left\{ \frac{M_j - Y_j}{M_j (1 - p_j)} \right\} \right]\right)^{1/2}$$

where the sign is the same as the sign of $(Y_j - M_j p_j)$. In the limiting cases, the deviance residual is given by

$$d_j = \begin{cases} 
- \sqrt{2M_j \ln(1 - p_j)} & \text{if } Y_j = 0 \\
\sqrt{2M_j \ln p_j} & \text{if } Y_j = M_j 
\end{cases}$$

The unadjusted diagonal elements of the hat matrix $h_{Uj}$ are given by $h_{Uj} = (XVX')_{jj}$, where $V$ is the estimated covariance matrix of parameters. The adjusted diagonal elements $h_j$ created by `hat` are then $h_j = M_j p_j (1 - p_j) h_{Uj}$.

The standardized Pearson residual $r_{Sj}$ is $r_j / \sqrt{1 - h_j}$. 
The Pregibon (1981) $\Delta \hat{\beta}_j$ influence statistic is

$$
\Delta \hat{\beta}_j = \frac{r^2_j h_j}{(1 - h_j)^2}
$$

The corresponding change in the Pearson $\chi^2$ is $r^2_{Sj}$. The corresponding change in the deviance residual is $\Delta D_j = d^2_j / (1 - h_j)$.

**logit — Logistic regression, reporting coefficients**

**Description**

`logit` fits a logit model for a binary response by maximum likelihood; it models the probability of a positive outcome given a set of regressors. `depvar` equal to nonzero and nonmissing (typically `depvar` equal to one) indicates a positive outcome, whereas `depvar` equal to zero indicates a negative outcome.

Also see [R] logistic; logistic displays estimates as odds ratios. Many users prefer the `logistic` command to `logit`. Results are the same regardless of which you use—both are the maximum-likelihood estimator. Several auxiliary commands that can be run after `logit`, `probit`, or `logistic` estimation are described in [R] logistic postestimation. A list of related estimation commands is given in [R] logistic.

**Quick start**

Logit model of `y` on `x1` and `x2`

```
logit y x1 x2
```

Add indicators for categorical variable `a`

```
logit y x1 x2 i.a
```

With cluster–robust standard errors for clustering by levels of `cvar`

```
logit y x1 x2 i.a, vce(cluster cvar)
```

Save separate coefficient estimates for each level of `cvar` to `myresults.dta`

```
statsby _b, by(cvar) saving(myresults): logit y x1 x2 i.a
```

Adjust for complex survey design using `svyset` data

```
svy: logit y x1 x2 i.a
```

`indepvars` may contain factor variables; see [U] 11.4.3 Factor variables.
`depvar` and `indepvars` may contain time-series operators; see [U] 11.4.4 Time-series varlists.
`bootstrap`, `by`, `fp`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 Prefix commands.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] mi estimate.

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.
`vce()`, `nocoef`, and weights are not allowed with the `svy` prefix; see [SVY] svy.
`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.
`nocoef` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

- Model `noconstant`, `offset(varname)`, `constraints(constraints)`, `collinear`; see [R] estimation options.

`asis` forces retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] probit.
vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

level(#) ; see [R] estimation options.

or reports the estimated coefficients transformed to odds ratios, that is, \( e^b \) rather than \( b \). Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. or may be specified at estimation or when replaying previously estimated results.

cnsonreport ; see [R] estimation options.

display_options : noci, nogvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, noflabel, fvwrap(#), fvwrapon(style), cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch ; see [R] estimation options.

Maximization

maximize_options : difficult, technique(algorithm_spec), iterate(#), [no] log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs) ; see [R] maximize. These options are seldom used.

The following options are available with logit but are not shown in the dialog box:

nocoef specifies that the coefficient table not be displayed. This option is sometimes used by program writers but is of no use interactively.

coefflegend ; see [R] estimation options.

Remarks and examples

Remarks are presented under the following headings:

Basic usage
Model identification

Basic usage

logit fits maximum likelihood models with dichotomous dependent (left-hand-side) variables coded as 0/1 (or, more precisely, coded as 0 and not-0).

For grouped data or data in binomial form, a probit model can be fit using glm with the family(binomial) and link(logit) options.

Example 1

We have data on the make, weight, and mileage rating of 22 foreign and 52 domestic automobiles. We wish to fit a logit model explaining whether a car is foreign on the basis of its weight and mileage. Here is an overview of our data:
. use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
. keep make mpg weight foreign
. describe

(2 unique values)

foreign is labeled and all values are documented in the label.

The variable `foreign` takes on two unique values, 0 and 1. The value 0 denotes a domestic car, and 1 denotes a foreign car.

The model that we wish to fit is

$$Pr(foreign = 1) = F(\beta_0 + \beta_1 weight + \beta_2 mpg)$$

where $F(z) = e^z/(1 + e^z)$ is the cumulative logistic distribution.
To fit this model, we type

```
.logit foreign weight mpg
```

Iteration 0: log likelihood = -45.03321
Iteration 1: log likelihood = -29.238536
Iteration 2: log likelihood = -27.244139
Iteration 3: log likelihood = -27.175277
Iteration 4: log likelihood = -27.175156
Iteration 5: log likelihood = -27.175156

Logistic regression

|       | Coef. | Std. Err. | z     | P>|z| | [95% Conf. Interval] |
|-------|-------|-----------|-------|-----|----------------------|
| weight| -.0039067 | .0010116 | -3.86 | 0.000 | -.0058894 to -.001924 |
| mpg   | -.1685869 | .0919175 | -1.83 | 0.067 | -.3487418 to .011568  |
| _cons | 13.70837  | 4.518709 | 3.03  | 0.002| 4.851859 to 22.56487  |

We find that heavier cars are less likely to be foreign and that cars yielding better gas mileage are also less likely to be foreign, at least holding the weight of the car constant.

Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if your dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

If you prefer a more formal mathematical statement, when you type `logit y x`, Stata fits the model

\[ Pr(y_j \neq 0 | x_j) = \frac{\exp(x_j\beta)}{1 + \exp(x_j\beta)} \]

Model identification

The `logit` command has one more feature, and it is probably the most useful. `logit` automatically checks the model for identification and, if it is underidentified, drops whatever variables and observations are necessary for estimation to proceed. (`logistic`, `probit`, and `ivprobit` do this as well.)

Example 2

Have you ever fit a logit model where one or more of your independent variables perfectly predicted one or the other outcome?

For instance, consider the following data:

<table>
<thead>
<tr>
<th>Outcome</th>
<th>Independent variable x</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>
Say that we wish to predict the outcome on the basis of the independent variable. The outcome is always zero whenever the independent variable is one. In our data, \( \Pr(y = 0 \mid x = 1) = 1 \), which means that the logit coefficient on \( x \) must be minus infinity with a corresponding infinite standard error. At this point, you may suspect that we have a problem.

Unfortunately, not all such problems are so easily detected, especially if you have a lot of independent variables in your model. If you have ever had such difficulties, you have experienced one of the more unpleasant aspects of computer optimization. The computer has no idea that it is trying to solve for an infinite coefficient as it begins its iterative process. All it knows is that at each step, making the coefficient a little bigger, or a little smaller, works wonders. It continues on its merry way until either 1) the whole thing comes crashing to the ground when a numerical overflow error occurs or 2) it reaches some predetermined cutoff that stops the process. In the meantime, you have been waiting. The estimates that you finally receive, if you receive any at all, may be nothing more than numerical roundoff.

Stata watches for these sorts of problems, alerts us, fixes them, and properly fits the model.

Let’s return to our automobile data. Among the variables we have in the data is one called \textit{repair}, which takes on three values. A value of 1 indicates that the car has a poor repair record, 2 indicates an average record, and 3 indicates a better-than-average record. Here is a tabulation of our data:

```
use http://www.stata-press.com/data/r14/repair, clear
(1978 Automobile Data)
tabulate foreign repair
```

<table>
<thead>
<tr>
<th>Car type</th>
<th>repair</th>
<th></th>
<th></th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domestic</td>
<td>10</td>
<td>27</td>
<td>9</td>
<td>46</td>
</tr>
<tr>
<td>Foreign</td>
<td>0</td>
<td>3</td>
<td>9</td>
<td>12</td>
</tr>
<tr>
<td>Total</td>
<td>10</td>
<td>30</td>
<td>18</td>
<td>58</td>
</tr>
</tbody>
</table>

All the cars with poor repair records (\textit{repair} = 1) are domestic. If we were to attempt to predict \textit{foreign} on the basis of the repair records, the predicted probability for the \textit{repair} = 1 category would have to be zero. This in turn means that the logit coefficient must be minus infinity, and that would set most computer programs buzzing.
Let’s try Stata on this problem.

```
.logit foreign b3.repair
```

```
note: 1.repair != 0 predicts failure perfectly
1.repair dropped and 10 obs not used
```

Iteration 0: log likelihood = -26.992087
Iteration 1: log likelihood = -22.483187
Iteration 2: log likelihood = -22.230498
Iteration 3: log likelihood = -22.229139
Iteration 4: log likelihood = -22.229138

Logistic regression Number of obs = 48
LR chi2(1) = 9.53
Prob > chi2 = 0.0020
Log likelihood = -22.229138 Pseudo R2 = 0.1765

| foreign | Coef.   | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|---------|---------|-----------|------|-----|---------------------|
| repair  |         |           |      |     |                     |
| 1       | 0 (empty) |           |      |     |                     |
| 2       | -2.197225 | .7698003  | -2.85 | 0.004 | -3.706005 to -.688436 |
| _cons   | 7.94e-17 | .4714045  | 0.00 | 1.000 | -.9239359 to .9239359 |

Remember that all the cars with poor repair records (repair = 1) are domestic, so the model cannot be fit, or at least it cannot be fit if we restrict ourselves to finite coefficients. Stata noted that fact “note: 1.repair !=0 predicts failure perfectly”. This is Stata’s mathematically precise way of saying what we said in English. When repair is 1, the car is domestic.

Stata then went on to say “1.repair dropped and 10 obs not used”. This is Stata eliminating the problem. First 1.repair had to be removed from the model because it would have an infinite coefficient. Then the 10 observations that led to the problem had to be eliminated, as well, so as not to bias the remaining coefficients in the model. The 10 observations that are not used are the 10 domestic cars that have poor repair records.

Stata then fit what was left of the model, using the remaining observations. Because no observations remained for cars with poor repair records, Stata reports “(empty)” in the row for repair = 1.

Technical note

Stata is pretty smart about catching problems like this. It will catch “one-way causation by a dummy variable”, as we demonstrated above.

Stata also watches for “two-way causation”, that is, a variable that perfectly determines the outcome, both successes and failures. Here Stata says, “so-and-so predicts outcome perfectly” and stops. Statistics dictates that no model can be fit.

Stata also checks your data for collinear variables; it will say, “so-and-so omitted because of collinearity”. No observations need to be eliminated in this case, and model fitting will proceed without the offending variable.

It will also catch a subtle problem that can arise with continuous data. For instance, if we were estimating the chances of surviving the first year after an operation, and if we included in our model age, and if all the persons over 65 died within the year, Stata would say, “age > 65 predicts failure perfectly”. It would then inform us about the fix-up it takes and fit what can be fit of our model.
logit (and logistic, probit, and ivprobit) will also occasionally display messages such as

Note: 4 failures and 0 successes completely determined.

There are two causes for a message like this. The first—and most unlikely—case occurs when a continuous variable (or a combination of a continuous variable with other continuous or dummy variables) is simply a great predictor of the dependent variable. Consider Stata’s auto.dta dataset with 6 observations removed.

```
. use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
. drop if foreign==0 & gear_ratio > 3.1
(6 observations deleted)
. logit foreign mpg weight gear_ratio, nolog
Logistic regression
Number of obs = 68
LR chi2(3) = 72.64
Prob > chi2 = 0.0000
Log likelihood = -6.4874814 Pseudo R2 = 0.8484

foreign             Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
-------------    -------------------    -------    --------    -------------------
      mpg            -.4944907   .2655508    -1.86   0.063    -.1014961   .0259792
     weight          -.0060919   .0031010    -1.96   0.049    -.0121698  -0.000014
    gear_ratio         15.70509   8.166234     1.92   0.054    -.300436   31.71061
      _cons           -21.39527   25.41486    -0.84   0.400   -71.20747   28.41694
```

Note: 4 failures and 0 successes completely determined.

There are no missing standard errors in the output. If you receive the “completely determined” message and have one or more missing standard errors in your output, see the second case discussed below.

Note gear_ratio’s large coefficient. logit thought that the 4 observations with the smallest predicted probabilities were essentially predicted perfectly.

```
. predict p
(option pr assumed; Pr(foreign))
. sort p
. list p in 1/4

     p
 1. 1.34e-10
 2. 6.26e-09
 3. 7.84e-09
 4. 1.49e-08
```

If this happens to you, you do not have to do anything. Computationally, the model is sound. The second case discussed below requires careful examination.

The second case occurs when the independent terms are all dummy variables or continuous ones with repeated values (for example, age). Here one or more of the estimated coefficients will have missing standard errors. For example, consider this dataset consisting of 6 observations.
. use http://www.stata-press.com/data/r14/logitxmpl, clear
. list, separator(0)

Logistic regression
Number of obs = 6
LR chi2(1) =  2.09
Prob > chi2 = 0.1480
Log likelihood = -2.7725887  Pseudo R2 = 0.2740

|     | Coef. | Std. Err. |      z  |   P>|z| |   95% Conf. Interval |
|-----|-------|-----------|--------|--------|----------------------|
| x1  |  18.3704 |    2.0000 |  9.19  | 0.000  |  14.45047  22.29033 |
| x2  |  18.3704 |    .       |  9.19  | 0.000  | -21.14221 -15.5986  |
| _cons | -18.3704 |  1.414214 | -12.99 | 0.000  | -21.14221 -15.5986  |

Note: 2 failures and 0 successes completely determined.
(convergence not achieved)
r(430);
. egen pattern = group(x1 x2)
. quietly logit y x1 x2, iterate(100)
. predict p
    (option pr assumed; Pr(y))
. summarize p

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>p</td>
<td>6</td>
<td>.3333333</td>
<td>.2581989</td>
<td>1.05e-08</td>
<td>.5</td>
</tr>
</tbody>
</table>

If successes were completely determined, that means that there are predicted probabilities that are almost 1. If failures were completely determined, that means that there are predicted probabilities that are almost 0. The latter is the case here, so we locate the corresponding value of `pattern`:

. tabulate pattern if p < 1e-7

<table>
<thead>
<tr>
<th>group(x1 x2)</th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>100.00</td>
<td>100.00</td>
</tr>
<tr>
<td>Total</td>
<td>2</td>
<td>100.00</td>
<td></td>
</tr>
</tbody>
</table>

Once we omit this covariate pattern from the estimation sample, `logit` can deal with the collinearity:

. logit y x1 x2 if pattern != 1, nolog
    note: x2 omitted because of collinearity

Logistic regression
    Number of obs = 4
    LR chi2(1) = 0.00
    Prob > chi2 = 1.0000
    Log likelihood = -2.7725887 Pseudo R2 = 0.0000

| y     | Coef.  | Std. Err. | z     | P>|z|  | [95% Conf. Interval] |
|-------|--------|-----------|-------|------|---------------------|
| x1    | 0      | 2         | 0.00  | 1.00 | -3.919928            | 3.919928 |
| x2    | 0 (omitted) | 1.414214 | 0.00  | 1.00 | -2.771808            | 2.771808 |

We omit the collinear variable. Then we must decide whether to include or omit the observations with `pattern = 1`. We could include them,

. logit y x1, nolog

Logistic regression
    Number of obs = 6
    LR chi2(1) = 0.37
    Prob > chi2 = 0.5447
    Log likelihood = -3.6356349 Pseudo R2 = 0.0480

| y     | Coef.  | Std. Err. | z     | P>|z|  | [95% Conf. Interval] |
|-------|--------|-----------|-------|------|---------------------|
| x1    | 1.098612 | 1.825742  | 0.60  | 0.547 | -2.479776            | 4.677001 |
| _cons | -1.098612 | 1.154701  | -0.95 | 0.341 | -3.361784            | 1.164559 |
or exclude them,

```
.logit y x1 if pattern != 1, nolog
```

Logistic regression

```
Number of obs = 4
LR chi2(1) = 0.00
Prob > chi2 = 1.0000
Log likelihood = -2.7725887 Pseudo R2 = 0.0000
```

| y     | Coef. | Std. Err. | z     | P>|z|  | [95% Conf. Interval] |
|-------|-------|-----------|-------|------|----------------------|
| x1    | 0     | 2         | 0.00  | 1.000| -3.919928 3.919928   |
| _cons | 0     | 1.414214  | 0.00  | 1.000| -2.771808 2.771808   |

If the covariate pattern that predicts outcome perfectly is meaningful, you may want to exclude these observations from the model. Here you would report that covariate pattern such and such predicted outcome perfectly and that the best model for the rest of the data is.... But, more likely, the perfect prediction was simply the result of having too many predictors in the model. Then you would omit the extraneous variables from further consideration and report the best model for all the data.

**Stored results**

`logit` stores the following in `e()`:

Scalars

- `e(N)` number of observations
- `e(N_cds)` number of completely determined successes
- `e(N_cdf)` number of completely determined failures
- `e(k)` number of parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(r2_p)` pseudo-$R$-squared
- `e(ll)` log likelihood
- `e(ll_0)` log likelihood, constant-only model
- `e(N_clust)` number of clusters
- `e(chi2)` chi-squared
- `e(p)` significance of model test
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise
Macros

- \( e(cmd) \): command as typed
- \( e(cmdline) \): name of dependent variable
- \( e(wtype) \): weight type
- \( e(wexp) \): weight expression
- \( e(title) \): title in estimation output
- \( e(clustvar) \): name of cluster variable
- \( e(offset) \): linear offset variable
- \( e(chi2type) \): Wald or LR; type of model \( \chi^2 \) test
- \( e(vcetype) \): type of optimization
- \( e(which) \): \texttt{ml} method
- \( e(model) \): name of likelihood-evaluator program
- \( e(properties) \): type of \texttt{ml} method
- \( e(estat\_cmd) \): program used to implement \texttt{estat}
- \( e(predict) \): program used to implement \texttt{predict}
- \( e(marginsnotok) \): predictions disallowed by \texttt{margins}
- \( e(asbalanced) \): factor variables \texttt{fvset} as \texttt{asbalanced}
- \( e(asobserved) \): factor variables \texttt{fvset} as \texttt{asobserved}

Matrices

- \( e(b) \): coefficient vector
- \( e(Cns) \): constraints matrix
- \( e(iilog) \): iteration log (up to 20 iterations)
- \( e(gradient) \): gradient vector
- \( e(mns) \): vector of means of the independent variables
- \( e(rules) \): information about perfect predictors
- \( e(V) \): variance–covariance matrix of the estimators
- \( e(V\_modelbased) \): model-based variance

Functions

- \( e(sample) \): marks estimation sample

### Methods and formulas

Cramer (2003, chap. 9) surveys the prehistory and history of the logit model. The word “logit” was coined by Berkson (1944) and is analogous to the word “probit”. For an introduction to probit and logit, see, for example, Aldrich and Nelson (1984), Cameron and Trivedi (2010), Greene (2012), Jones (2007), Long (1997), Long and Freese (2014), Pampel (2000), or Powers and Xie (2008).

The likelihood function for logit is

\[
\ln L = \sum_{j \in S} w_j \ln F(x_j \beta) + \sum_{j \not\in S} w_j \ln \left( 1 - F(x_j \beta) \right)
\]
where $S$ is the set of all observations $j$, such that $y_j \neq 0$, $F(z) = e^z/(1 + e^z)$, and $w_j$ denotes the optional weights. $\ln L$ is maximized as described in \texttt{[R} maximize].

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See \texttt{[P} \_robust, particularly \textit{Maximum likelihood estimators} and \textit{Methods and formulas}. The scores are calculated as $u_j = \{1 - F(x_j b)\}x_j$ for the positive outcomes and $-F(x_j b)x_j$ for the negative outcomes.

\texttt{logit} also supports estimation with survey data. For details on VCEs with survey data, see \texttt{[SVY} variance estimation].

Joseph Berkson (1899–1982) was born in New York City and studied at the College of the City of New York, Columbia, and Johns Hopkins, earning both an MD and a doctorate in statistics. He then worked at Johns Hopkins before moving to the Mayo Clinic in 1931 as a biostatistician. Among many other contributions, his most influential one drew upon a long-sustained interest in the logistic function, especially his 1944 paper on bioassay, in which he introduced the term “logit”. Berkson was a frequent participant in controversy—sometimes humorous, sometimes bitter—on subjects such as the evidence for links between smoking and various diseases and the relative merits of probit and logit methods and of different calculation methods.

Postestimation commands

The following postestimation commands are of special interest after `logit`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>estat classification</code></td>
<td>report various summary statistics, including the classification table</td>
</tr>
<tr>
<td><code>estat gof</code></td>
<td>Pearson or Hosmer–Lemeshow goodness-of-fit test</td>
</tr>
<tr>
<td><code>lroc</code></td>
<td>compute area under ROC curve and graph the curve</td>
</tr>
<tr>
<td><code>lsens</code></td>
<td>graph sensitivity and specificity versus probability cutoff</td>
</tr>
</tbody>
</table>

These commands are not appropriate after the `svy` prefix.

The following standard postestimation commands are also available:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>contrast</code></td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td><code>estat ic</code></td>
<td>Akaike’s and Schwarz’s Bayesian information criteria (AIC and BIC)</td>
</tr>
<tr>
<td><code>estat summarize</code></td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td><code>estat vce</code></td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td><code>estat (svy)</code></td>
<td>postestimation statistics for survey data</td>
</tr>
<tr>
<td><code>estimates</code></td>
<td>cataloging estimation results</td>
</tr>
<tr>
<td><code>forecast</code></td>
<td>dynamic forecasts and simulations</td>
</tr>
<tr>
<td><code>hausman</code></td>
<td>Hausman’s specification test</td>
</tr>
<tr>
<td><code>lincom</code></td>
<td>point estimates, standard errors, testing, and inference for linear combinations of coefficients</td>
</tr>
<tr>
<td><code>linktest</code></td>
<td>link test for model specification</td>
</tr>
<tr>
<td><code>lrtest</code></td>
<td>likelihood-ratio test</td>
</tr>
<tr>
<td><code>margins</code></td>
<td>marginal means, predictive margins, marginal effects, and average marginal effects</td>
</tr>
<tr>
<td><code>marginsplot</code></td>
<td>graph the results from margins (profile plots, interaction plots, etc.)</td>
</tr>
<tr>
<td><code>nlcom</code></td>
<td>point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients</td>
</tr>
<tr>
<td><code>predict</code></td>
<td>predictions, residuals, influence statistics, and other diagnostic measures</td>
</tr>
<tr>
<td><code>predictnl</code></td>
<td>point estimates, standard errors, testing, and inference for generalized predictions</td>
</tr>
<tr>
<td><code>pwcompare</code></td>
<td>pairwise comparisons of estimates</td>
</tr>
<tr>
<td><code>suest</code></td>
<td>seemingly unrelated estimation</td>
</tr>
<tr>
<td><code>test</code></td>
<td>Wald tests of simple and composite linear hypotheses</td>
</tr>
<tr>
<td><code>testnl</code></td>
<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.
predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, standard errors, influence statistics, deviance residuals, leverages, sequential numbers, Pearson residuals, and equation-level scores.

Menu for predict

Syntax for predict

```
predict [type] newvar [if] [in] [ , statistic nooffset rules asif ]

<td>first derivative of the log likelihood with respect to $x_j \beta$</td>
</tr>
</tbody>
</table>

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

pr, xb, stdp, and score are the only options allowed with `svy` estimation results.

Options for predict

- **Main**
  - pr, the default, calculates the probability of a positive outcome.
  - xb calculates the linear prediction.
  - stdp calculates the standard error of the linear prediction.
  - dbeta calculates the Pregibon (1981) $\Delta \hat{\beta}$ influence statistic, a standardized measure of the difference in the coefficient vector that is due to deletion of the observation along with all others that share the same covariate pattern. In Hosmer, Lemeshow, and Sturdivant (2013, 154–155) jargon, this statistic is $M$-asymptotic; that is, it is adjusted for the number of observations that share the same covariate pattern.
deviance calculates the deviance residual.

dx2 calculates the Hosmer, Lemeshow, and Sturdivant (2013, 191) $\Delta \chi^2$ influence statistic, reflecting the decrease in the Pearson $\chi^2$ that is due to deletion of the observation and all others that share the same covariate pattern.

ddeviance calculates the Hosmer, Lemeshow, and Sturdivant (2013, 191) $\Delta D$ influence statistic, which is the change in the deviance residual that is due to deletion of the observation and all others that share the same covariate pattern.

hat calculates the Pregibon (1981) leverage or the diagonal elements of the hat matrix adjusted for the number of observations that share the same covariate pattern.

number numbers the covariate patterns—observations with the same covariate pattern have the same number. Observations not used in estimation have number set to missing. The first covariate pattern is numbered 1, the second 2, and so on.

residuals calculates the Pearson residual as given by Hosmer, Lemeshow, and Sturdivant (2013, 155) and adjusted for the number of observations that share the same covariate pattern.

rstandard calculates the standardized Pearson residual as given by Hosmer, Lemeshow, and Sturdivant (2013, 191) and adjusted for the number of observations that share the same covariate pattern.

score calculates the equation-level score, $\partial \ln L / \partial (x_j \beta)$.

\begin{verbatim}
Options
\end{verbatim}

nooffset is relevant only if you specified offset(varname) for logit. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $x_j \beta$ rather than as $x_j \beta + \text{offset}_j$.

rules requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations.

asif requests that Stata ignore the rules and exclusion criteria and calculate predictions for all observations possible by using the estimated parameter from the model.
margins

Description for margins

margins estimates margins of response for probabilities and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

\texttt{margins} \[marginlist]\ [, \textit{options}\]
\texttt{margins} \[marginlist]\ , \texttt{predict(statistic \dots)} \[\texttt{predict(statistic \dots) \dots}\] [\textit{options}]

<table>
<thead>

</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than \(e(b)\).

For the full syntax, see [R] margins.

Remarks and examples

Once you have fit a logit model, you can obtain the predicted probabilities by using the \texttt{predict} command for both the estimation sample and other samples; see [U] 20 Estimation and postestimation commands and [R] predict. Here we will make only a few more comments.

\texttt{predict} without arguments calculates the predicted probability of a positive outcome, that is, \(\Pr(y_j = 1) = F(x_jb)\). With the \texttt{xb} option, \texttt{predict} calculates the linear combination \(x_jb\), where \(x_j\) are the independent variables in the \(j\)th observation and \(b\) is the estimated parameter vector. This is sometimes known as the index function because the cumulative distribution function indexed at this value is the probability of a positive outcome.

In both cases, Stata remembers any rules used to identify the model and calculates missing for excluded observations, unless \texttt{rules} or \texttt{asif} is specified. For information about the other statistics available after \texttt{predict}, see [R] logistic postestimation.
Example 1: Predicted probabilities

In example 2 of [R] logit, we fit the logit model `logit foreign b3.repair`. To obtain predicted probabilities, type

```
. use http://www.stata-press.com/data/r14/repair
(1978 Automobile Data)
. logit foreign b3.repair
note: 1.repair != 0 predicts failure perfectly
    1.repair dropped and 10 obs not used
(output omitted)
. predict p
(option pr assumed; Pr(foreign))
(10 missing values generated)
. summarize foreign p
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign</td>
<td>58</td>
<td>.2069</td>
<td>.4086</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>p</td>
<td>48</td>
<td>.25</td>
<td>.1956</td>
<td>.1</td>
<td>.5</td>
</tr>
</tbody>
</table>

Stata remembers any rules used to identify the model and sets predictions to missing for any excluded observations. `logit` dropped the variable `1.repair` from our model and excluded 10 observations. Thus when we typed `predict p`, those same 10 observations were again excluded, and their predictions were set to missing.

`predict`'s `rules` option uses the rules in the prediction. During estimation, we were told “1.repair != 0 predicts failure perfectly”, so the rule is that when `1.repair` is not zero, we should predict 0 probability of success or a positive outcome:

```
. predict p2, rules
(option pr assumed; Pr(foreign))
. summarize foreign p p2
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign</td>
<td>58</td>
<td>.2069</td>
<td>.4086</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>p</td>
<td>48</td>
<td>.25</td>
<td>.1956</td>
<td>.1</td>
<td>.5</td>
</tr>
<tr>
<td>p2</td>
<td>58</td>
<td>.2069</td>
<td>.2016</td>
<td>0</td>
<td>.5</td>
</tr>
</tbody>
</table>

`predict`'s `asif` option ignores the rules and exclusion criteria and calculates predictions for all observations possible by using the estimated parameters from the model:

```
. predict p3, asif
(option pr assumed; Pr(foreign))
. summarize foreign p p2 p3
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign</td>
<td>58</td>
<td>.2069</td>
<td>.4086</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>p</td>
<td>48</td>
<td>.25</td>
<td>.1956</td>
<td>.1</td>
<td>.5</td>
</tr>
<tr>
<td>p2</td>
<td>58</td>
<td>.2069</td>
<td>.2016</td>
<td>0</td>
<td>.5</td>
</tr>
<tr>
<td>p3</td>
<td>58</td>
<td>.2931</td>
<td>.2016</td>
<td>.1</td>
<td>.5</td>
</tr>
</tbody>
</table>

Which is right? What `predict` does by default is the most conservative approach. If many observations had been excluded because of a simple rule, we could be reasonably certain that the `rules` prediction is correct. The `asif` prediction is correct only if the exclusion is a fluke, and we would be willing to exclude the variable from the analysis anyway. Then, however, we would refit the model to include the excluded observations.
Example 2: Predictive margins

We can use the command `margins, contrast` after `logit` to make comparisons on the probability scale. Let’s fit a model predicting low birthweight from characteristics of the mother:

```
. use http://www.stata-press.com/data/r14/lbw, clear
(Hosmer & Lemeshow data)
. logit low age i.race i.smoke ptl i.ht i.ui
```

The coefficients are log odds-ratios: conditional on the other predictors, smoking during pregnancy is associated with an increase of 0.96 in the log odds of low birthweight. The model is linear in the log odds-scale, so the estimate of 0.96 has the same interpretation, whatever the values of the other predictors might be. We could convert 0.96 to an odds ratio by replaying the results with `logit`, or.

But what if we want to talk about the probability of low birthweight, and not the odds? Then we will need the command `margins, contrast`. We will use the `r.` contrast operator to compare each level of `smoke` with a reference level. (`smoke` has only two levels, so there will be only one comparison: a comparison of smokers with nonsmokers.)

```
. use http://www.stata-press.com/data/r14/lbw, clear
(Hosmer & Lemeshow data)
. logit low age i.race i.smoke ptl i.ht i.ui
```

</tbody>
</table>

(smoker vs nonsmoker)

We see that maternal smoking is associated with an 18.3% increase in the probability of low birthweight. (We received a contrast in the probability scale because predicted probabilities are the default when margins is used after logit.)

The contrast of 18.3% is a difference of margins that are computed by averaging over the predictions for observations in the estimation sample. If the values of the other predictors were different, the contrast for smoke would be different, too. Let’s estimate the contrast for 25-year-old mothers:

. margins r.smoke, contrast at(age=25)
Contrasts of predictive margins
Model VCE : OIM
Expression : Pr(low), predict()
at : age = 25

<table>
<thead>
<tr>
<th></th>
<th>df</th>
<th>chi2</th>
<th>P&gt;chi2</th>

</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Delta-method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contrast</td>
</tr>
<tr>
<td>smoke</td>
</tr>
</tbody>
</table>

(smoker vs nonsmoker)

Specifying a maternal age of 25 changed the contrast to 18.1%. Our contrast of probabilities changed because the logit model is nonlinear in the probability scale. A contrast of log odds would not have changed.

Methods and formulas

See Methods and formulas of the individual postestimation commands for details.

[U] 20 Estimation and postestimation commands
Description

loneway fits one-way analysis-of-variance (ANOVA) models. loneway relaxes the restriction imposed by oneway that factors must have fewer than 376 levels. The command additionally reports the intraclass correlation, its standard error, and confidence interval; the estimated reliability of the group-averaged mean; the standard deviation of the group effect; and the standard deviation of the within-group effect.

Quick start

One-way ANOVA model of $y$ for factor $a$

loneway y a

Report an exact 95% confidence interval for the intraclass correlation

loneway y a, exact

As above, but report a 90% confidence interval

loneway y a, exact level(90)

Remarks are presented under the following headings:

- The one-way ANOVA model
- R-squared
- The random-effects ANOVA model
- Intraclass correlation
- Estimated reliability of the group-averaged score
The one-way ANOVA model

Example 1

loneway’s output looks like that of oneway, except that loneway presents more information at the end. Using our automobile dataset, we have created a (numeric) variable called manufacturer_grp identifying the manufacturer of each car, and within each manufacturer we have retained a maximum of four models, selecting those with the lowest mpg. We can compute the intraclass correlation of mpg for all manufacturers with at least four models as follows:

```
. use http://www.stata-press.com/data/r14/auto7
(1978 Automobile Data)
. loneway mpg manufacturer_grp if nummake == 4
```

One-way Analysis of Variance for mpg: Mileage (mpg)

In addition to the standard one-way ANOVA output, loneway produces the R-squared, the estimated standard deviation of the group effect, the estimated standard deviation within group, the intragroup correlation, the estimated reliability of the group-averaged mean, and, for unweighted data, the asymptotic standard error and confidence interval for the intragroup correlation.

R-squared

The R-squared is, of course, simply the underlying $R^2$ for a regression of response_var on the levels of group_var, or mpg on the various manufacturers here.

The random-effects ANOVA model

loneway assumes that we observe a variable, $y_{ij}$, measured for $n_i$ elements within $k$ groups or classes such that

$$y_{ij} = \mu + \alpha_i + \epsilon_{ij}, \quad i = 1, 2, \ldots, k, \quad j = 1, 2, \ldots, n_i$$

and $\alpha_i$ and $\epsilon_{ij}$ are independent zero-mean random variables with variance $\sigma^2_\alpha$ and $\sigma^2_\epsilon$, respectively. This is the random-effects ANOVA model, also known as the components-of-variance model, in which it is typically assumed that the $y_{ij}$ are normally distributed.
The interpretation with respect to our example is that the observed value of our response variable, \( \text{mpg} \), is created in two steps. First, the \( i \)th manufacturer is chosen, and a value, \( \alpha_i \), is determined—the typical \( \text{mpg} \) for that manufacturer less the overall \( \text{mpg} \) \( \mu \). Then a deviation, \( \epsilon_{ij} \), is chosen for the \( j \)th model within this manufacturer. This is how much that particular automobile differs from the typical \( \text{mpg} \) value for models from this manufacturer.

For our sample of 36 car models, the estimated standard deviations are \( \sigma_\alpha = 3.8 \) and \( \sigma_\epsilon = 4.6 \). Thus a little more than half of the variation in \( \text{mpg} \) between cars is attributable to the car model, with the rest attributable to differences between manufacturers. These standard deviations differ from those that would be produced by a (standard) fixed-effects regression in that the regression would require the sum within each manufacturer of the \( \epsilon_{ij} \), \( \epsilon_i \), for the \( i \)th manufacturer, to be zero, whereas these estimates merely impose the constraint that the sum is expected to be zero.

Intraclass correlation

There are various estimators of the intraclass correlation, such as the pairwise estimator, which is defined as the Pearson product-moment correlation computed over all possible pairs of observations that can be constructed within groups. For a discussion of various estimators, see Donner (1986). `loneway` computes what is termed the analysis of variance, or ANOVA, estimator. This intraclass correlation is the theoretical upper bound on the variation in \( \text{response\_var} \) that is explainable by \( \text{group\_var} \), of which \( R \)-squared is an overestimate because of the serendipity of fitting. This correlation is comparable to an \( R \)-squared—you do not have to square it.

In our example, the intra\(-\text{manu} \) correlation, the correlation of \( \text{mpg} \) within manufacturer, is 0.40. Because \text{aweights} were not used and the default correlation was computed (that is, the \text{mean} and \text{median} options were not specified), `loneway` also provided the asymptotic confidence interval and standard error of the intraclass correlation estimate.

Estimated reliability of the group-averaged score

The estimated reliability of the group-averaged score or mean has an interpretation similar to that of the intragroup correlation; it is a comparable number if we average \( \text{response\_var} \) by \( \text{group\_var} \), or \( \text{mpg} \) by \text{manu} in our example. It is the theoretical upper bound of a regression of manufacturer-averaged \( \text{mpg} \) on characteristics of manufacturers. Why would we want to collapse our 36-observation dataset into a 9-observation dataset of manufacturer averages? Because the 36 observations might be a mirage. When General Motors builds cars, do they sometimes put a Pontiac label and sometimes a Chevrolet label on them, so that it appears in our data as if we have two cars when we really have only one, replicated? If that were the case, and if it were the case for many other manufacturers, then we would be forced to admit that we do not have data on 36 cars; we instead have data on nine manufacturer-averaged characteristics.

Stored results

`loneway` stores the following in \( r() \):

<table>
<thead>
<tr>
<th>Scalars</th>
<th>Description</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>( r(N) )</td>
<td>number of observations</td>
<td>( r(\text{rho}_t) ) estimated reliability</td>
</tr>
<tr>
<td>( r(\text{rho}) )</td>
<td>intraclass correlation</td>
<td>( r(\text{se}) ) asymp. SE of intraclass correlation</td>
</tr>
<tr>
<td>( r(\text{lb}) )</td>
<td>lower bound of 95% CI for rho</td>
<td>( r(\text{sd}_w) ) estimated SD within group</td>
</tr>
<tr>
<td>( r(\text{ub}) )</td>
<td>upper bound of 95% CI for rho</td>
<td>( r(\text{sd}_b) ) estimated SD of group effect</td>
</tr>
</tbody>
</table>

The estimated reliability of the group-averaged score or mean has an interpretation similar to that of the intragroup correlation; it is a comparable number if we average \text{response\_var} by \text{group\_var}, or \text{mpg} by \text{manu} in our example. It is the theoretical upper bound of a regression of manufacturer-averaged \text{mpg} on characteristics of manufacturers. Why would we want to collapse our 36-observation dataset into a 9-observation dataset of manufacturer averages? Because the 36 observations might be a mirage. When General Motors builds cars, do they sometimes put a Pontiac label and sometimes a Chevrolet label on them, so that it appears in our data as if we have two cars when we really have only one, replicated? If that were the case, and if it were the case for many other manufacturers, then we would be forced to admit that we do not have data on 36 cars; we instead have data on nine manufacturer-averaged characteristics.
Methods and formulas

The mean squares in the loneway’s ANOVA table are computed as

$$\text{MS}_\alpha = \sum_i w_i (\bar{y}_i - \bar{y}..)^2 / (k - 1)$$

and

$$\text{MS}_\epsilon = \sum_i \sum_j w_{ij} (y_{ij} - \bar{y}_i)^2 / (N - k)$$

in which

$$w_i = \sum_j w_{ij} \quad w.. = \sum_i w_i \quad \bar{y}_i = \sum_j w_{ij} y_{ij} / w_i \quad \text{and} \quad \bar{y}.. = \sum_i w_i \bar{y}_i / w..$$

The corresponding expected values of these mean squares are

$$E(\text{MS}_\alpha) = \sigma_\epsilon^2 + g \sigma_\alpha^2 \quad \text{and} \quad E(\text{MS}_\epsilon) = \sigma_\epsilon^2$$

in which

$$g = \frac{w.. - \sum_i w_i^2 / w..}{k - 1}$$

In the unweighted case, we get

$$g = \frac{N - \sum_i n_i^2 / N}{k - 1}$$

As expected, $g = m$ for the case of no weights and equal group sizes in the data, that is, $n_i = m$ for all $i$. Replacing the expected values with the observed values and solving yields the ANOVA estimates of $\sigma_\alpha^2$ and $\sigma_\epsilon^2$. Substituting these into the definition of the intraclass correlation

$$\rho = \frac{\sigma_\alpha^2}{\sigma_\alpha^2 + \sigma_\epsilon^2}$$

yields the ANOVA estimator of the intraclass correlation:

$$\rho_A = \frac{F_{\text{obs}} - 1}{F_{\text{obs}} - 1 + g}$$

$F_{\text{obs}}$ is the observed value of the $F$ statistic from the ANOVA table. For no weights and equal $n_i$, $\rho_A = \text{roh}$, which is the intragroup correlation defined by Kish (1965). Two slightly different estimators are available through the mean and median options (Gleason 1997). If either of these options is specified, the estimate of $\rho$ becomes

$$\rho = \frac{F_{\text{obs}} - F_m}{F_{\text{obs}} + (g - 1)F_m}$$

For the mean option, $F_m = E(F_{k-1,N-k}) = (N-k)/(N-k-2)$, that is, the expected value of the ANOVA table’s $F$ statistic. For the median option, $F_m$ is simply the median of the $F$ statistic. Setting $F_m$ to 1 gives $\rho_A$, so for large samples, these different point estimators are essentially the same. Also, because the intraclass correlation of the random-effects model is by definition nonnegative, for any of the three possible point estimators, $\rho$ is truncated to zero if $F_{\text{obs}}$ is less than $F_m$. 
For no weighting, interval estimators for $\rho_A$ are computed. If the groups are equal sized (all $n_i$ equal) and the exact option is specified, the following exact (assuming that the $y_{ij}$ are normally distributed) 100(1 - $\alpha$)% confidence interval is computed:

$$\left\{ \frac{F_{\text{obs}} - F_{mF}}{F_{\text{obs}} + (g - 1)F_{mF}}, \frac{F_{\text{obs}} - F_{mF}}{F_{\text{obs}} + (g - 1)F_{mF}} \right\}$$

with $F_m = 1$, $F_l = F_{\alpha/2,k-1,N-k}$, and $F_u = F_{1-\alpha/2,k-1,N-k}$, $F_{k-1,N-k}$ being the cumulative distribution function for the $F$ distribution with $k - 1$ and $N - k$ degrees of freedom. If mean or median is specified, $F_m$ is defined as above. If the groups are equal sized and exact is not specified, the following asymptotic 100(1 - $\alpha$)% confidence interval for $\rho_A$ is computed,

$$\left[ \rho_A - z_{\alpha/2} \sqrt{V(\rho_A)}, \rho_A + z_{\alpha/2} \sqrt{V(\rho_A)} \right]$$

where $z_{\alpha/2}$ is the 100(1 - $\alpha/2$) percentile of the standard normal distribution and $\sqrt{V(\rho_A)}$ is the asymptotic standard error of $\rho$ defined below. This confidence interval is also available for unequal groups. It is not applicable and, therefore, not computed for the estimates of $\rho$ provided by the mean and median options. Again, because the intraclass coefficient is nonnegative, if the lower bound is negative for either confidence interval, it is truncated to zero. As might be expected, the coverage probability of a truncated interval is higher than its nominal value.

The asymptotic standard error of $\rho_A$, assuming that the $y_{ij}$ are normally distributed, is also computed when appropriate, namely, for unweighted data and when $\rho_A$ is computed (neither the mean option nor the median option is specified):

$$V(\rho_A) = \frac{2(1 - \rho)^2}{g^2} (A + B + C)$$

with

$$A = \frac{\{1 + \rho(g - 1)\}^2}{N - k}$$

$$B = \frac{(1 - \rho)(1 + \rho(2g - 1))}{k - 1}$$

$$C = \rho^2 \left\{ \sum n_i^2 - 2N^{-1} \sum n_i^3 + N^{-2} (\sum n_i^2)^2 \right\} / (k - 1)^2$$

and $\rho_A$ is substituted for $\rho$ (Donner 1986).

The estimated reliability of the group-averaged score, known as the Spearman–Brown prediction formula in the psychometric literature (Winer, Brown, and Michels 1991, 1014), is

$$\rho_t = \frac{t \rho}{1 + (t - 1)\rho}$$

for group size $t$. loneway computes $\rho_t$ for $t = g$.

The estimated standard deviation of the group effect is $\sigma_\alpha = \sqrt{(MS_\alpha - MS_\epsilon) / g}$. This deviation comes from the assumption that an observation is derived by adding a group effect to a within-group effect.

The estimated standard deviation within group is the square root of the mean square due to error, or $\sqrt{MS_\epsilon}$.

**Acknowledgment**

We thank John Gleason of Syracuse University (retired) for his contributions to improving loneway.

Description

`lowess` carries out a locally weighted regression of `yvar` on `xvar`, displays the graph, and optionally saves the smoothed variable.

Warning: `lowess` is computationally intensive and may therefore take a long time to run on a slow computer. Lowess calculations on 1,000 observations, for instance, require performing 1,000 regressions.

Quick start

Locally weighted regression of `y1` on `x`

```
lowess y1 x
```

As above, but with a bandwidth of 0.4

```
lowess y1 x, bwidth(.4)
```

With running-mean smoothing

```
lowess y1 x, mean
```

Without the tricube weighting function

```
lowess y1 x, noweight
```

Generate a new variable `v` containing the smoothed values of `y1`

```
lowess y1 x, generate(v)
```

Adjust the mean of the smoothed values to equal the mean of the unsmoothed values

```
lowess y1 x, adjust
```

Lowess smoothing of categorical variable `y2` on `x` in terms of the log of the odds ratio

```
lowess y2 x, logit
```

Statistics > Nonparametric analysis > Lowess smoothing
Syntax

`lowess yvar xvar [if] [in] [, options]`

.options  Description

Main
- `mean`  running-mean smooth; default is running-line least squares
- `noweight`  suppress weighted regressions; default is tricube weighting function
- `bwidth(#)`  use # for the bandwidth; default is `bwidth(0.8)`
- `logit`  transform dependent variable to logits
- `adjust`  adjust smoothed mean to equal mean of dependent variable
- `nograph`  suppress graph
- `generate(newvar)`  create `newvar` containing smoothed values of `yvar`

Plot
- `marker_options`  change look of markers (color, size, etc.)
- `marker_label_options`  add marker labels; change look or position

Smoothed line
- `lineopts(cline_options)`  affect rendition of the smoothed line

Add plots
- `addplot(plot)`  add other plots to generated graph

Y axis, X axis, Titles, Legend, Overall, By
- `twoway_options`  any of the options documented in [G-3] `twoway_options`

`yvar` and `xvar` may contain time-series operators; see [U] 11.4.4 Time-series varlists.

Options

`mean` specifies running-mean smoothing; the default is running-line least-squares smoothing.

`noweight` prevents the use of Cleveland’s (1979) tricube weighting function; the default is to use the weighting function.

`bwidth(#)` specifies the bandwidth. Centered subsets of $bwidth() \times N$ observations are used for calculating smoothed values for each point in the data except for the end points, where smaller, uncentered subsets are used. The greater the `bwidth()`, the greater the smoothing. The default is 0.8.

`logit` transforms the smoothed `yvar` into logits. Predicted values less than 0.0001 or greater than 0.9999 are set to $1/N$ and $1 - 1/N$, respectively, before taking logits.

`adjust` adjusts the mean of the smoothed `yvar` to equal the mean of `yvar` by multiplying by an appropriate factor. This option is useful when smoothing binary (0/1) data.

`nograph` suppresses displaying the graph.

`generate(newvar)` creates `newvar` containing the smoothed values of `yvar`. 
Plot

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] marker_options.

marker_label_options specify if and how the markers are to be labeled; see [G-3] marker_label_options.

lineopts(cline_options) affects the rendition of the lowess-smoothed line; see [G-3] cline_options.

addplot(plot) provides a way to add other plots to the generated graph; see [G-3] addplot_option.

twoway_options are any of the options documented in [G-3] twoway_options. These include options for titling the graph (see [G-3] title_options), options for saving the graph to disk (see [G-3] saving_option), and the by() option (see [G-3] by_option).

Remarks and examples

By default, lowess provides locally weighted scatterplot smoothing. The basic idea is to create a new variable (newvar) that, for each yvar $y_i$, contains the corresponding smoothed value. The smoothed values are obtained by running a regression of yvar on xvar by using only the data $(x_i, y_i)$ and a few of the data near this point. In lowess, the regression is weighted so that the central point $(x_i, y_i)$ gets the highest weight and points that are farther away (based on the distance $|x_j - x_i|$) receive less weight. The estimated regression line is then used to predict the smoothed value $\hat{y}_i$ for $y_i$ only. The procedure is repeated to obtain the remaining smoothed values, which means that a separate weighted regression is performed for every point in the data.

Lowess is a desirable smoother because of its locality—it tends to follow the data. Polynomial smoothing methods, for instance, are global in that what happens on the extreme left of a scatterplot can affect the fitted values on the extreme right.

Example 1

The amount of smoothing is affected by bwidth(#). You are warned to experiment with different values. For instance,
. use http://www.stata-press.com/data/r14/lowess1
(example data for lowess)
. lowess h1 depth

Now compare that with

. lowess h1 depth, bwidth(.4)

In the first case, the default bandwidth of 0.8 is used, meaning that 80% of the data are used in smoothing each point. In the second case, we explicitly specified a bandwidth of 0.4. Smaller bandwidths follow the original data more closely.

Example 2

Two *lowess* options are especially useful with binary (0/1) data: *adjust* and *logit*. *adjust* adjusts the resulting curve (by multiplication) so that the mean of the smoothed values is equal to the mean of the unsmoothed values. *logit* specifies that the smoothed curve be in terms of the log of the odds ratio:
. use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
. lowess foreign mpg, ylabel(0 "Domestic" 1 "Foreign") jitter(5) adjust

With binary data, if you do not use the logit option, it is a good idea to specify graph’s jitter() option; see [G-2] graph twoway scatter. Because the underlying data (whether the car was manufactured outside the United States here) take on only two values, raw data points are more likely to be on top of each other, thus making it impossible to tell how many points there are. graph’s jitter() option adds some noise to the data to shift the points around. This noise affects only the location of points on the graph, not the lowess curve.

When you specify the logit option, the display of the raw data is suppressed.
Technical note

Lowess can be used for more than just lowess smoothing. Lowess can be usefully thought of as a combination of two smoothing concepts: the use of predicted values from regression (rather than means) for imputing a smoothed value and the use of the tricube weighting function (rather than a constant weighting function). Lowess allows you to combine these concepts freely. You can use line smoothing without weighting (specify `noweight`), mean smoothing with tricube weighting (specify `mean`), or mean smoothing without weighting (specify `mean` and `noweight`).

Methods and formulas

Let $y_i$ and $x_i$ be the two variables, and assume that the data are ordered so that $x_i \leq x_{i+1}$ for $i = 1, \ldots, N - 1$. For each $y_i$, a smoothed value $y_i^s$ is calculated.

The subset used in calculating $y_i^s$ is indices $i_- = \max(1, i-k)$ through $i_+ = \min(i+k, N)$, where $k = \lfloor (N \times \text{bwidth} - 0.5)/2 \rfloor$. The weights for each of the observations between $j = i_-, \ldots, i_+$ are either 1 (`noweight`) or the tricube (default),

$$w_j = \left\{1 - \left( \frac{|x_j - x_i|}{\Delta} \right)^3 \right\}^3$$

where $\Delta = 1.0001 \max(x_{i+} - x_i, x_i - x_{i-})$. The smoothed value $y_i^s$ is then the (weighted) mean or the (weighted) regression prediction at $x_i$.

William Swain Cleveland (1943– ) studied mathematics and statistics at Princeton and Yale. He worked for several years at Bell Labs in New Jersey and now teaches statistics and computer science at Purdue. He has made key contributions in many areas of statistics, including graphics and data visualization, time series, environmental applications, and analysis of Internet traffic data.

[R] \texttt{smooth} — Robust nonlinear smoother

[D] \texttt{ipolate} — Linearly interpolate (extrapolate) values
## Description

`lpoly` performs a kernel-weighted local polynomial regression of `yvar` on `xvar` and displays a graph of the smoothed values with (optional) confidence bands.

### Quick start

Kernel-weighted local polynomial regression of `y` on `x`

```
lpoly y x
```

As above, but specify a bandwidth of 2

```
lpoly y x, bwidth(2)
```

As above, but specify a degree of 1

```
lpoly y x, bwidth(2) degree(1)
```

As above, but use the alternative Epanechnikov kernel

```
lpoly y x, bwidth(2) degree(1) kernel(epan2)
```

As above, but create a new variable for the smoothing grid `g` and smoothed values `s`

```
lpoly y x, bwidth(2) degree(1) kernel(epan2) generate(g s)
```

With 95% confidence bands

```
lpoly y x, ci
```

Use `twoway` to graph multiple local polynomial fits

```
twoway scatter y x ||
    lpoly y x, degree(1) kernel(epan2) ||
    lpoly y x, degree(1) kernel(epan2) bwidth(1) ||
    lpoly y x, degree(1) kernel(epan2) bwidth(7) ||
```

-fweights and aweights are allowed; see [U] 11.1.6 weight.

**Note:**

- `kernel(kernel)` specifies the kernel function for use in calculating the weighted local polynomial estimate. The default is `kernel(epanechnikov)`.
- `bwidth(# | varname)` specifies the half-width of the kernel—the width of the smoothing window around each point. If `bwidth()` is not specified, a rule-of-thumb (ROT) bandwidth estimator is calculated and used. A local variable bandwidth may be specified in `varname`, in conjunction with an explicit smoothing grid using the `at()` option.
- `degree(#)` specifies the degree of the polynomial to be used in the smoothing. The default is `degree(0)`, meaning local-mean smoothing.
- `generate([newvar_x] newvar_s)` stores the smoothing grid in `newvar_x` and the smoothed values in `newvar_s`. If `at()` is not specified, then both `newvar_x` and `newvar_s` must be specified. Otherwise, only `newvar_s` is to be specified.
- `n(#)` specifies the number of points at which the smooth is to be calculated. The default is `min(N, 50)`, where `N` is the number of observations.
- `at(varname)` specifies a variable that contains the values at which the smooth should be calculated. By default, the smoothing is done on an equally spaced grid, but you can use `at()` to instead perform the smoothing at the observed `x`'s, for example. This option also allows you to more easily obtain smooths for different variables or different subsamples of a variable and then overlay the estimates for comparison.
- `nograph` suppresses drawing the graph of the estimated smooth. This option is often used with the `generate()` option.
- `noscatter` suppresses superimposing a scatterplot of the observed data over the smooth. This option is useful when the number of resulting points would be so large as to clutter the graph.
- `ci` plots confidence bands, using the confidence level specified in `level()`.
- `level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.7 Specifying the width of confidence intervals.
- `se(newvar)` stores the estimates of the standard errors in `newvar`. This option requires specifying `generate()` or `at()`.
pwidth(#) specifies the pilot bandwidth to be used for standard-error computations. The default is chosen to be 1.5 times the value of the \texttt{ROT} bandwidth selector. If you specify \texttt{pwidth()} without specifying \texttt{se()} or \texttt{ci}, then the \texttt{ci} option is assumed.

\texttt{var(# | varname)} specifies an estimate of a constant residual variance or a variable containing estimates of the residual variances at each grid point required for standard-error computation. By default, the residual variance at each smoothing point is estimated by the normalized weighted residual sum of squares obtained from locally fitting a polynomial of order \( p + 2 \), where \( p \) is the degree specified in \texttt{degree()}. \texttt{var(varname)} is allowed only if \texttt{at()} is specified. If you specify \texttt{var()} without specifying \texttt{se()} or \texttt{ci}, then the \texttt{ci} option is assumed.

\texttt{var(\# | varname)} specifies an estimate of a constant residual variance or a variable containing estimates of the residual variances at each grid point required for standard-error computation. By default, the residual variance at each smoothing point is estimated by the normalized weighted residual sum of squares obtained from locally fitting a polynomial of order \( p + 2 \), where \( p \) is the degree specified in \texttt{degree()}. \texttt{var(varname)} is allowed only if \texttt{at()} is specified. If you specify \texttt{var()} without specifying \texttt{se()} or \texttt{ci}, then the \texttt{ci} option is assumed.

---

**Remarks and examples**

Remarks are presented under the following headings:

- Introduction
- Local polynomial smoothing
- Choice of a bandwidth
- Confidence bands

**Introduction**

The last 25 years or so has seen a significant outgrowth in the literature on scatterplot smoothing, otherwise known as univariate nonparametric regression. Of most appeal is the idea of making no assumptions about the functional form for the expected value of a response given a regressor, but instead allowing the data to “speak for themselves”. Various methods and estimators fall into the category of nonparametric regression, including local mean smoothing as described independently by Nadaraya (1964) and Watson (1964), the Gasser and Müller (1979) estimator, locally weighted scatterplot smoothing (LOWESS) as described by Cleveland (1979), wavelets (for example, Donoho
Local polynomial smoothing

Consider a set of scatterplot data \( \{(x_1, y_1), \ldots, (x_n, y_n)\} \) from the model

\[
y_i = m(x_i) + \sigma(x_i)\epsilon_i
\]

for some unknown mean and variance functions \( m(\cdot) \) and \( \sigma^2(\cdot) \), and symmetric errors \( \epsilon_i \) with \( E(\epsilon_i) = 0 \) and \( \text{Var}(\epsilon_i) = 1 \). The goal is to estimate \( m(x_0) = E[Y|X = x_0] \), making no assumption about the functional form of \( m(\cdot) \).

`lpoly` estimates \( m(x_0) \) as the constant term (intercept) of a regression, weighted by the kernel function specified in `kernel()`, of `yvar` on the polynomial terms \( (xvar - x_0), (xvar - x_0)^2, \ldots, (xvar - x_0)^p \) for each smoothing point \( x_0 \). The degree of the polynomial, \( p \), is specified in `degree()`, the amount of smoothing is controlled by the bandwidth specified in `bwidth()`, and the chosen kernel function is specified in `kernel()`.

Example 1

Consider the motorcycle data as examined (among other places) in Fan and Gijbels (1996). The data consist of 133 observations and measure the acceleration (`accel` measured in grams [g]) of a dummy’s head during impact over time (`time` measured in milliseconds). For these data, we use `lpoly` to fit a local cubic polynomial with the default bandwidth (obtained using the ROT method) and the default Epanechnikov kernel.
. use http://www.stata-press.com/data/r14/motorcycle
(Motorcycle data from Fan & Gijbels (1996))
. lpoly accel time, degree(3)

The default bandwidth and kernel settings do not provide a satisfactory fit in this example. To improve the fit, we can either supply a different bandwidth by using the \texttt{bwidth()} option or specify a different kernel by using the \texttt{kernel()} option. For example, using the alternative Epanechnikov kernel, \texttt{kernel(epan2)}, below provides a better fit for these data.

. lpoly accel time, degree(3) kernel(epan2)

\textbf{Technical note}

\texttt{lpoly} allows specifying in \texttt{degree()} both odd and even orders of the polynomial to be used for the smoothing. However, the odd-order, $2k + 1$, polynomial approximations are preferable. They have
Choice of a bandwidth

The choice of a bandwidth is crucial for many smoothing techniques, including local polynomial smoothing. In general, using a large bandwidth gives smooths with a large bias, whereas a small bandwidth may result in highly variable smoothed values. Various techniques exist for optimal bandwidth selection. By default, \texttt{lpoly} uses the \texttt{ROT} method to estimate the bandwidth used for the smoothing; see \textit{Methods and formulas} for details.

Example 2

Using the motorcycle data, we demonstrate how a local linear polynomial fit changes using different bandwidths.

\begin{verbatim}
. lpoly accel time, degree(1) kernel(epan2) bwidth(1) generate(at smooth1) > nograph
. lpoly accel time, degree(1) kernel(epan2) bwidth(7) at(at) generate(smooth2) > nograph
. label variable smooth1 "smooth: width = 1"
. label variable smooth2 "smooth: width = 7"
. lpoly accel time, degree(1) kernel(epan2) at(at) addplot(line smooth* at) > legend(label(2 "smooth: width = 3.42 (ROT)")) note("kernel = epan2, degree = 1")
\end{verbatim}

From this graph, we can see that the local linear polynomial fit with larger bandwidth (\texttt{width = 7}) corresponds to a smoother line but fails to fit the curvature of the scatterplot data. The smooth obtained using the width equal to one seems to fit most data points, but the corresponding line has several spikes indicating larger variability. The smooth obtained using the ROT bandwidth estimator seems to have a good tradeoff between the fit and variability in this example.
In the above, we also demonstrated how the `generate()` and `addplot()` options may be used to produce overlaid plots obtained from `lpoly` with different options. The `nograph` option saves time when you need to save only results with `generate()`.

However, to avoid generating variables manually, one can use `twoway` `lpoly` instead; see [G-2] `graph twoway lpoly` for more details.

```
. twoway scatter accel time ||
  >   lpoly accel time, degree(1) kernel(epan2) lpattern(solid) ||
  >   lpoly accel time, degree(1) kernel(epan2) bwidth(1) ||
  >   lpoly accel time, degree(1) kernel(epan2) bwidth(7) ||
  >   , legend(label(2 "smooth: width = 3.42 (ROT)") label(3 "smooth: width = 1")
  >   label(4 "smooth: width = 7"))
  >   title("Local polynomial smooth") note("kernel = epan2, degree = 1")
  >   xtitle("time (msec)") ytitle("acceleration (g)")
```

The ROT estimate is commonly used as an initial guess for the amount of smoothing; this approach may be sufficient when the choice of a bandwidth is less important. In other cases, you can pick your own bandwidth.

When the shape of the regression function has a combination of peaked and flat regions, a variable bandwidth may be preferable over the constant bandwidth to allow for different degrees of smoothness in different regions. The `bwidth()` option allows you to specify the values of the local variable bandwidths as those stored in a variable in your data.

Similar issues with bias and variability arise when choosing a pilot bandwidth (the `pwidth()` option) used to compute standard errors of the local polynomial smoother. The default value is chosen to be $1.5 \times \text{ROT}$. For a review of methods for pilot bandwidth selection, see Fan and Gijbels (1996).

**Confidence bands**

The established asymptotic normality of the local polynomial estimators under certain conditions allows the construction of approximate confidence bands. `lpoly` offers the `ci` option to plot these bands.
Example 3

Let us plot the confidence bands for the local polynomial fit from example 1.

```
.lpoly accel time, degree(3) kernel(epan2) ci
```

![Local polynomial smooth](image)

You can obtain graphs with overlaid confidence bands by using `twoway lpolyci`; see [G-2] graph twoway lpolyci for examples.

Constructing the confidence intervals involves computing standard errors obtained by taking a square root of the estimate of the conditional variance of the local polynomial estimator at each grid point $x_0$. Estimating the conditional variance requires fitting a polynomial of a higher order locally by using a different bandwidth, the pilot bandwidth. The value of the pilot bandwidth may be supplied by using `pwidth()`. By default, the value of $1.5 \times ROT$ is used. Also, estimates of the residual variance $\sigma^2(x_0)$ at each grid point, $x_0$, are required to obtain the estimates of the conditional variances. These estimates may be supplied by using the `var()` option. By default, they are computed using the normalized weighted residual sum of squares from a local polynomial fit of a higher order. See Methods and formulas for details. The standard errors may be saved by using `se()`.

Stored results

`lpoly` stores the following in `r()`:

Scalars
- `r(degree)` smoothing polynomial degree
- `r(ngrid)` number of successful regressions
- `r(N)` sample size
- `r(bwidth)` bandwidth of the smooth
- `r(pwidth)` pilot bandwidth

Macros
- `r(kernel)` name of kernel
Methods and formulas

Consider model (1), written in matrix notation,

\[ y = m(x) + \epsilon \]

where \( y \) and \( x \) are the \( n \times 1 \) vectors of scatterplot values, \( \epsilon \) is the \( n \times 1 \) vector of errors with zero mean and covariance matrix \( \Sigma = \text{diag}\{\sigma(x_i)\}I_n \), and \( m() \) and \( \sigma() \) are some unknown functions. Define \( m(x_0) = E[Y|X = x_0] \) and \( \sigma^2(x_0) = \text{Var}[Y|X = x_0] \) to be the conditional mean and conditional variance of random variable \( Y \) (residual variance), respectively, for some realization \( x_0 \) of random variable \( X \).

The method of local polynomial smoothing is based on the approximation of \( m(x) \) locally by a \( p \)th order polynomial in \((x - x_0)\) for some \( x \) in the neighborhood of \( x_0 \). For the scatterplot data \( \{(x_1, y_1), \ldots, (x_n, y_n)\} \), the \( p \)th-order local polynomial smooth \( \hat{m}(x_0) \) is equal to \( \hat{\beta}_0 \), an estimate of the intercept of the weighted linear regression,

\[
\hat{\beta} = (X^T W X)^{-1} X^T W y
\]

where \( \hat{\beta} = (\hat{\beta}_0, \hat{\beta}_1, \ldots, \hat{\beta}_p)^T \) is the vector of estimated regression coefficients (with \( \{\hat{\beta}_j = (j!)^{-1}\hat{m}(j)(x)|_{x=x_0}, j = 0, \ldots, p\} \) also representing estimated coefficients from a corresponding Taylor expansion); \( X = \{(x_i - x_0)^j\}_{i,j=0,1}^{n,p} \) is a design matrix; and \( W = \text{diag}\{K_h(x_i - x_0)\}_{n \times n} \) is a weighting matrix with weights \( K_h(\cdot) \) defined as \( K_h(x) = h^{-1}K(x/h) \), with \( K(\cdot) \) being a kernel function and \( h \) defining a bandwidth. The kernels are defined in Methods and formulas of [R] kdensity.

The default bandwidth is obtained using the ROT method of bandwidth selection. The ROT bandwidth is the plugin estimator of the asymptotically optimal constant bandwidth. This is the bandwidth that minimizes the conditional weighted mean integrated squared error. The ROT plugin bandwidth selector for the smoothing bandwidth \( h \) is defined as follows; assuming constant residual variance \( \sigma^2(x_0) = \sigma^2 \) and odd degree \( p \):

\[
\hat{h} = C_{0,p}(K) \left[ \frac{\hat{\sigma}^2 \int w_0(x)dx}{n \int \{\hat{m}^{(p+1)}(x)\}^2 w_0(x)f(x)dx} \right]^{1/(2p+3)}
\]

where \( C_{0,p}(K) \) is a constant, as defined in Fan and Gijbels (1996), that depends on the kernel function \( K(\cdot) \), and the degree of a polynomial \( p \) and \( w_0 \) is chosen to be an indicator function on the interval \([\min_x + 0.05 \times \text{range}_x, \max_x - 0.05 \times \text{range}_x] \) with \( \min_x \), \( \max_x \), and \( \text{range}_x \) being, respectively, the minimum, maximum, and the range of \( x \). To obtain the estimates of a constant residual variance, \( \hat{\sigma}^2 \), and \((p + 1)\)th order derivative of \( m(x) \), denoted as \( \hat{m}^{(p+1)}(x) \), a polynomial in \( x \) of order \((p + 3)\) is fit globally to \( y \). \( \hat{\sigma}^2 \) is estimated as a standardized residual sum of squares from this fit.

The expression for the asymptotically optimal constant bandwidth used in constructing the ROT bandwidth estimator is derived for the odd-order polynomial approximations. For even-order polynomial fits the expression would depend not only on \( m^{(p+1)}(x) \) but also on \( m^{(p+2)}(x) \) and the design density and its derivative, \( f(x) \) and \( f'(x) \). Therefore, the ROT bandwidth selector would require estimation of these additional quantities. Instead, for an even-degree \( p \) of the local polynomial, 1poly uses the value of the ROT estimator (3) computed using degree \( p + 1 \). As such, for even degrees this is not a plugin estimator of the asymptotically optimal constant bandwidth.

The estimates of the conditional variance of local polynomial estimators are obtained using

\[
\overline{\text{Var}}\{\hat{m}(x_0)|X = x_0\} = \hat{\sigma}_m^2(x_0) = (X^T W X)^{-1}(X^T W^2 X)(X^T W X)^{-1}\hat{\sigma}^2(x_0)
\]
where $\hat{\sigma}^2(x_0)$ is estimated by the normalized weighted residual sum of squares from the $(p + 2)$th order polynomial fit using pilot bandwidth $h^*$. When the bias is negligible the normal-approximation method yields a $(1 - \alpha) \times 100\%$ confidence interval for $m(x_0)$,

$$\left\{ \hat{m}(x_0) - z_{(1-\alpha/2)} \hat{\sigma}_m(x_0), \hat{m}(x_0) + z_{(1-\alpha/2)} \hat{\sigma}_m(x_0) \right\}$$

where $z_{(1-\alpha/2)}$ is the $(1 - \alpha/2)$th quantile of the standard Gaussian distribution, and $\hat{m}(x_0)$ and $\hat{\sigma}_m(x_0)$ are as defined in (2) and (4), respectively.

fweights are allowed; see [U] 11.1.6 weight.
lroc is not appropriate after the svy prefix.

Options

Main

all requests that the statistic be computed for all observations in the data, ignoring any if or in restrictions specified by the estimation command.
nograph suppresses graphical output.

Advanced

beta(matname) specifies a row vector containing model coefficients. The columns of the row vector must be labeled with the corresponding names of the independent variables in the data. The dependent variable depvar must be specified immediately after the command name. See Models other than the last fitted model later in this entry.

Plot

cline_options, marker_options, and marker_label_options affect the rendition of the ROC curve—the plotted points connected by lines. These options affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] cline_options, [G-3] marker_options, and [G-3] marker_label_options.
Reference line

rlopts(cline_options) affects the rendition of the reference line; see [G-3] cline_options.

Add plots

addplot(plot) provides a way to add other plots to the generated graph; see [G-3] addplot_option.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] twoway_options, excluding by(). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

Remarks and examples

Remarks are presented under the following headings:

Introduction

Stata also has a suite of commands for performing both parametric and nonparametric receiver operating characteristic (ROC) analysis. See [R] roc for an overview of these commands.

lroc graphs the ROC curve—a graph of sensitivity versus one minus specificity as the cutoff $c$ is varied—and calculates the area under it. Sensitivity is the fraction of observed positive-outcome cases that are correctly classified; specificity is the fraction of observed negative-outcome cases that are correctly classified. When the purpose of the analysis is classification, you must choose a cutoff.

The curve starts at $(0, 0)$, corresponding to $c = 1$, and continues to $(1, 1)$, corresponding to $c = 0$. A model with no predictive power would be a $45^\circ$ line. The greater the predictive power, the more bowed the curve, and hence the area beneath the curve is often used as a measure of the predictive power. A model with no predictive power has area 0.5; a perfect model has area 1.

The ROC curve was first discussed in signal detection theory (Peterson, Birdsall, and Fox 1954) and then was quickly introduced into psychology (Tanner and Swets 1954). It has since been applied in other fields, particularly medicine (for instance, Metz [1978]). For a classic text on ROC techniques, see Green and Swets (1966).

lsens also plots sensitivity and specificity; see [R] lsens.

Example 1

Hardin and Hilbe (2012) examine data from the National Canadian Registry of Cardiovascular Disease (FASTRAK), sponsored by Hoffman-La Roche Canada. They model death within 48 hours based on whether a patient suffers an anterior infarct (heart attack) rather than an inferior infarct using a logistic regression and evaluate the model using an ROC curve. We replicate their analysis here.

Both anterior and inferior refer to sites on the heart where damage occurs. The model is also adjusted for hcabg, whether the subject has had a cardiac bypass surgery (CABG); age, a four-category age-group indicator; and killip, a four-level risk indicator.
We load the data and then estimate the parameters of the logistic regression with `logistic`. Factor-variable notation is used for each predictor, because they are categorical; see [U] 11.4.3 Factor variables.

```
. use http://www.stata-press.com/data/r14/heart
(Heart attacks)

```

The odds ratios for a unit change in each covariate are reported by `logistic`. At fixed values of the other covariates, patients who enter Canadian hospitals with an anterior infarct have nearly twice the odds of death within 48 hours than those with an inferior infarct. Those who have had a previous CABG have approximately twice the risk of death of those who have not. Those with higher Killip risks and those who are older are also at greater risk of death.

We use `lroc` to draw the ROC curve for the model. The area under the curve of approximately 0.8 indicates acceptable discrimination for the model.
. lroc
Logistic model for death
number of observations = 4483
area under ROC curve = 0.7965

Samples other than the estimation sample

lroc can be used with samples other than the estimation sample. By default, lroc remembers the estimation sample used with the last logistic, logit, probit, or ivprobit command. To override this, simply use an if or in restriction to select another set of observations, or specify the all option to force the command to use all the observations in the dataset.

See example 3 in [R] estat gof for an example of using lroc with a sample other than the estimation sample.

Models other than the last fitted model

By default, lroc uses the last model fit by logistic, logit, probit, or ivprobit. You may also directly specify the model to lroc by inputting a vector of coefficients with the beta() option and passing the name of the dependent variable depvar to lroc.

Example 2

Suppose that someone publishes the following logistic model of low birthweight:
\[
\Pr(\text{low} = 1) = F(-0.02 \text{ age} - 0.01 \text{ lwt} + 1.3 \text{ black} + 1.1 \text{ smoke} + 0.5 \text{ ptl} + 1.8 \text{ ht} + 0.8 \text{ ui} + 0.5)
\]
where \(F\) is the cumulative logistic distribution. These coefficients are not odds ratios; they are the equivalent of what logit produces.

We can see whether this model fits our data. First we enter the coefficients as a row vector and label its columns with the names of the independent variables plus _cons for the constant (see [P] matrix define and [P] matrix rownames).
. use http://www.stata-press.com/data/r14/lbw3, clear
   (Hosmer & Lemeshow data)
. matrix input b = (-.02, -.01, 1.3, 1.1, .5, 1.8, .8, .5)
. matrix colnames b = age lwt black smoke ptl ht ui _cons

Here we use lroc to examine the predictive ability of the model:

   . lroc low, beta(b) nograph
Logistic model for low
   number of observations =  189
   area under ROC curve = 0.7275

The area under the curve indicates that this model does have some predictive power. We can obtain a graph of sensitivity and specificity as a function of the cutoff probability by typing

   . lsens low, beta(b)

See [R] lsens.

Stored results

lroc stores the following in r():

Scalars
   r(N)  number of observations
   r(area)  area under the ROC curve

Methods and formulas

The ROC curve is a graph of sensitivity against (1 – specificity). This is guaranteed to be a monotone nondecreasing function because the number of correctly predicted successes increases and the number of correctly predicted failures decreases as the classification cutoff \( c \) decreases.

The area under the ROC curve is the area on the bottom of this graph and is determined by integrating the curve. The vertices of the curve are determined by sorting the data according to the predicted index, and the integral is computed using the trapezoidal rule.

[U] 20 Estimation and postestimation commands
**Description**

`lrtest` performs a likelihood-ratio test of the null hypothesis that the parameter vector of a statistical model satisfies some smooth constraint. To conduct the test, both the unrestricted and the restricted models must be fit using the maximum likelihood method (or some equivalent method), and the results of at least one must be stored using `estimates store`.

`lrtest` also supports composite models. In a composite model, we assume that the log likelihood and dimension (number of free parameters) of the full model are obtained as the sum of the log-likelihood values and dimensions of the constituting models.

**Quick start**

Likelihood-ratio test that the coefficients for x2 and x3 are equal to 0

logit y x1 x2 x3
estimates store full
logit y x1 if e(sample)
estimates store restricted
lrtest full restricted

Display additional information, including AIC and BIC

lrtest full restricted, stats

Likelihood-ratio test that the coefficients for x1 and x3 are equal

constraint 1 x1=x3
logit y x1 x2 x3, constraints(1)estimates store constrained
lrtest full constrained

Compare stored estimates full to the last model run

lrtest full

**Menu**

Statistics > Postestimation
Syntax

```
lrtest modelspec1 [ modelspec2 ] [ , options ]
```

`modelspec1` and `modelspec2` specify the restricted and unrestricted model in any order. `modelspec#` is

```
name | . | (namelist)
```

`name` is the name under which estimation results were stored using `estimates store` (see [R] estimates store), and “.” refers to the last estimation results, whether or not these were already stored. If `modelspec2` is not specified, the last estimation result is used; this is equivalent to specifying `modelspec2` as “.”.

If `namelist` is specified for a composite model, `modelspec1` and `modelspec2` cannot have names in common; for example, `lrtest (A B C) (C D E)` is not allowed because both model specifications include `C`.

```
options                  Description
stats                   display statistical information about the two models
dir                      display descriptive information about the two models
df(#)                    override the automatic degrees-of-freedom calculation; seldom used
force                   force testing even when apparently invalid
```

Options

- **stats** displays statistical information about the unrestricted and restricted models, including the information indices of Akaike and Schwarz.
- **dir** displays descriptive information about the unrestricted and restricted models; see `estimates dir` in [R] estimates store.
- **df(#)** is seldom specified; it overrides the automatic degrees-of-freedom calculation.
- **force** forces the likelihood-ratio test calculations to take place in situations where `lrtest` would normally refuse to do so and issue an error. Such situations arise when one or more assumptions of the test are violated, for example, if the models were fit with `vce(robust)`, `vce(cluster clustvar)`, or `pweights`; when the dependent variables in the two models differ; when the null log likelihoods differ; when the samples differ; or when the estimation commands differ. If you use the `force` option, there is no guarantee as to the validity or interpretability of the resulting test.

Remarks and examples

The standard way to use `lrtest` is to do the following:

1. Fit either the restricted model or the unrestricted model by using one of Stata’s estimation commands and then store the results using `estimates store name`.
2. Fit the alternative model (the unrestricted or restricted model) and then type `lrtest name .`. `lrtest` determines for itself which of the two models is the restricted model by comparing the degrees of freedom.

Often you may want to store the alternative model with `estimates store name2`, for instance, if you plan additional tests against models yet to be fit. The likelihood-ratio test is then obtained as `lrtest name name2`. 
Remarks are presented under the following headings:

Nested models
Composite models

Nested models

`lrtest` may be used with any estimation command that reports a log likelihood, including `heckman`, `logit`, `poisson`, `stcox`, and `streg`. You must check that one of the model specifications implies a statistical model that is *nested within* the model implied by the other specification. Usually, this means that both models are fit with the same estimation command (for example, both are fit by `logit`, with the same dependent variables) and that the set of covariates of one model is a subset of the covariates of the other model. Second, `lrtest` is valid only for models that are fit by maximum likelihood or by some equivalent method, so it does not apply to models that were fit with probability weights or clusters. Specifying the `vce(robust)` option similarly would indicate that you are worried about the valid specification of the model, so you would not use `lrtest`. Third, `lrtest` assumes that under the null hypothesis, the test statistic is (approximately) distributed as chi-squared. This assumption is not true for likelihood-ratio tests of “boundary conditions”, such as tests for the presence of overdispersion or random effects (Gutiérrez, Carter, and Drukker 2001).

Example 1

We have data on infants born with low birthweights along with the characteristics of the mother (Hosmer, Lemeshow, and Sturdivant 2013; see also [R] `logistic`). We fit the following model:

```
. use http://www.stata-press.com/data/r14/lbw
(Hosmer & Lemeshow data)
. logistic low age lwt i.race smoke ptl ht ui
```

```
Logistic regression Number of obs = 189
LR chi2(8) = 33.22
Prob > chi2 = 0.0001

smoke             1.719161    .5952579  1.56  0.118      .8721455    3.388787
  ptl              6.249602    4.322408  2.65  0.008      1.611152    24.24199
  ht               2.1351     .9808153  1.65  0.099      .8677528    5.2534
  ui               1.586014    1.910496  0.38  0.702      .1496092    16.8134
_cons             6.249602    4.322408  2.65  0.008      1.611152    24.24199
```

We now wish to test the constraint that the coefficients on `age`, `lwt`, `ptl`, and `ht` are all zero or, equivalently here, that the odds ratios are all 1. One solution is to type
. test age lwt ptl ht
( 1) [low]age = 0
( 2) [low]lwt = 0
( 3) [low]ptl = 0
( 4) [low]ht = 0
    chi2( 4) = 12.38
    Prob > chi2 = 0.0147

This test is based on the inverse of the information matrix and is therefore based on a quadratic approximation to the likelihood function; see [R] test. A more precise test would be to refit the model, applying the proposed constraints, and then calculate the likelihood-ratio test.

We first save the current model:

. estimates store full

We then fit the constrained model, which here is the model omitting age, lwt, ptl, and ht:

. logistic low i.race smoke ui

Logistic regression                     Number of obs = 189
                                          LR chi2(4) = 18.80
                                          Prob > chi2 = 0.0009
Log likelihood = -107.93404            Pseudo R2 = 0.0801

Odds Ratio Std. Err.     z    P>|z|      [95% Conf. Interval]

race
  black   3.052746   1.498087  2.27  0.023      1.166747    7.987382

ui
  2.419131   1.047359  2.34  0.019      1.038459    5.651788
  _cons   0.1402209  0.0512295  5.38  0.000      0.0685216    0.2869447

That done, lrtest compares this model with the model we previously stored:

. lrtest full

Likelihood-ratio test                      LR chi2(4) = 14.42
(Assumption: . nested in full)              Prob > chi2 = 0.0061

Let’s compare results. test reported that age, lwt, ptl, and ht were jointly significant at the 1.5% level; lrtest reports that they are significant at the 0.6% level. Given the quadratic approximation made by test, we could argue that lrtest’s results are more accurate.

lrtest explicates the assumption that, from a comparison of the degrees of freedom, it has assessed that the last fit model (. ) is nested within the model stored as full. In other words, full is the unconstrained model and . is the constrained model.

The names in “(Assumption: . nested in full)” are actually links. Click on a name, and the results for that model are replayed.

Aside: The nestreg command provides a simple syntax for performing likelihood-ratio tests for nested model specifications; see [R] nestreg. In the previous example, we fit a full logistic model, used estimates store to store the full model, fit a constrained logistic model, and used lrtest to report a likelihood-ratio test between two models. To do this with one call to nestreg, use the lrtable option.
lrtest determines the degrees of freedom of a model as the rank of the (co)variance matrix $\mathbf{e}(V)$. There are two issues here. First, the numerical determination of the rank of a matrix is a subtle problem that can, for instance, be affected by the scaling of the variables in the model. The rank of a matrix depends on the number of (independent) linear combinations of coefficients that sum exactly to zero. In the world of numerical mathematics, it is hard to tell whether a very small number is really nonzero or is a real zero that happens to be slightly off because of roundoff error from the finite precision with which computers make floating-point calculations. Whether a small number is being classified as one or the other, typically on the basis of a threshold, affects the determined degrees of freedom. Although Stata generally makes sensible choices, it is bound to make mistakes occasionally. The moral of this story is to make sure that the calculated degrees of freedom is as you expect before interpreting the results.

A second issue involves *regress* and related commands such as *anova*. Mainly for historical reasons, *regress* does not treat the residual variance, $\sigma^2$, the same way that it treats the regression coefficients. Type *estat vce* after *regress*, and you will see the regression coefficients, not $\hat{\sigma}^2$. Most estimation commands for models with ancillary parameters (for example, *streg* and *heckman*) treat all parameters as equals. There is nothing technically wrong with *regress* here; we are usually focused on the regression coefficients, and their estimators are uncorrelated with $\hat{\sigma}^2$. But, formally, $\sigma^2$ adds a degree of freedom to the model, which does not matter if you are comparing two regression models by a likelihood-ratio test. This test depends on the difference in the degrees of freedom, and hence being “off by 1” in each does not matter. But, if you are comparing a regression model with a larger model—for example, a heteroskedastic regression model fit by *arch*—the automatic determination of the degrees of freedom is incorrect, and you must specify the df(#) option.

Returning to the low-birthweight data in the example 1, we now wish to test that the coefficient on 2.*race* (black) is equal to that on 3.*race* (other). The base model is still stored under the name `full`, so we need only fit the constrained model and perform the test. With $z$ as the index of the logit model, the base model is

$$z = \beta_0 + \beta_1 \text{age} + \beta_2 \text{lwt} + \beta_3 2.\text{race} + \beta_4 3.\text{race} + \cdots$$

If $\beta_3 = \beta_4$, this can be written as

$$z = \beta_0 + \beta_1 \text{age} + \beta_2 \text{lwt} + \beta_3 (2.\text{race} + 3.\text{race}) + \cdots$$
We can fit the constrained model as follows:

```
constraint 1 2.race = 3.race
.logistic low age lwt i.race smoke ptl ht ui, constraints(1)
```

Logistic regression

Comparing this model with our original model, we obtain

```
.lrtest full
```

Likelihood-ratio test LR chi2(1) = 0.55
(Assumption: . nested in full) Prob > chi2 = 0.4577

By comparison, typing `test 2.race=3.race` after fitting our base model results in a significance level of 0.4572. Alternatively, we can first store the restricted model, here using the name `equal`.

```
Next lrtest is invoked specifying the names of the restricted and unrestricted models (we do not care about the order). This time, we also add the option `stats` requesting a table of model statistics, including the model selection indices AIC and BIC.

```
. estimates store equal
. lrtest equal full, stats
```

Likelihood-ratio test LR chi2(1) = 0.55
(Assumption: equal nested in full) Prob > chi2 = 0.4577

Composite models

`lrtest` supports composite models; that is, models that can be fit by fitting a series of simpler models or by fitting models on subsets of the data. Theoretically, a composite model is one in which the likelihood function, \( L(\theta) \), of the parameter vector, \( \theta \), can be written as the product

\[
L(\theta) = L_1(\theta_1) \times L_2(\theta_2) \times \cdots \times L_k(\theta_k)
\]

of likelihood terms with \( \theta = (\theta_1, \ldots, \theta_k) \) a partitioning of the full parameter vector. In such a case, the full-model likelihood \( L(\theta) \) is maximized by maximizing the likelihood terms \( L_j(\theta_j) \) in turn. Obviously, \( \log L(\hat{\theta}) = \sum_{j=1}^{k} \log L_j(\hat{\theta}_j) \). The degrees of freedom for the composite model is obtained as the sum of the degrees of freedom of the constituting models.

Example 3

As an example of the application of composite models, we consider a test of the hypothesis that the coefficients of a statistical model do not differ between different portions (“regimes”) of the covariate space. Economists call a test for such a hypothesis a *Chow test*.

We continue the analysis of the data on children of low birthweight by using logistic regression modeling and study whether the regression coefficients are the same among the three races: white, black, and other. A likelihood-ratio Chow test can be obtained by fitting the logistic regression model for each of the races and then comparing the combined results with those of the model previously stored as `full`. Because the full model included dummies for the three races, this version of the Chow test allows the intercept of the logistic regression model to vary between the regimes (races).

Note: N=Obs used in calculating BIC; see [R] BIC note.

We cannot reject the hypothesis that the logistic regression model applies to each of the races at any reasonable significance level. By specifying the `stats` option, we can verify the degrees of freedom of the test: \(12 = 7 + 7 + 7 - 9\). We can obtain the same test by fitting an expanded model with interactions between all covariates and `race`. 
Applying `lrtest` for the full model against the model with all interactions yields the same test statistic and \( p \)-value as for the full model against the composite model for the three regimes. Here the specification of the model with interactions was convenient, and `logistic` had no problem computing the estimates for the expanded model. In models with more complicated likelihoods, such as Heckman’s selection model (see \([R]\) `heckman`) or complicated survival-time models (see \([ST]\) `streg`), fitting the models with all interactions may be numerically demanding and may be much more time consuming than fitting a series of models separately for each regime.

Given the model with all interactions, we could also test the hypothesis of no differences among the regions (races) by a Wald version of the Chow test by using the `testparm` command; see \([R]\) `test`.

. testparm race#c.(age lwt smoke ptl ht ui)
( 1) [low]2.race#c.age = 0
( 2) [low]3.race#c.age = 0
( 3) [low]2.race#c.lwt = 0
( 4) [low]3.race#c.lwt = 0
( 5) [low]2.race#c.smoke = 0
( 6) [low]3.race#c.smoke = 0
( 7) [low]2.race#c.ptl = 0
( 8) [low]3.race#c.ptl = 0
( 9) [low]2.race#c.ht = 0
(10) [low]3.race#c.ht = 0
(11) [low]2.race#c.ui = 0
(12) [low]3.race#c.ui = 0

   ch2( 12) =  8.24
   Prob > ch2 =  0.7663

We conclude that, here, the Wald version of the Chow test is similar to the likelihood-ratio version of the Chow test.

Stored results

`lrtest` stores the following in `r()`:  

Scalars  
   r(p)     level of significance  
   r(df)    degrees of freedom  
   r(chi2)  LR test statistic  

Programmers wishing their estimation commands to be compatible with `lrtest` should note that `lrtest` requires that the following results be returned:  
   e(cmd)    name of estimation command  
   e(ll)     log likelihood  
   e(V)      variance–covariance matrix of the estimators  
   e(N)      number of observations  

`lrtest` also verifies that `e(N)`, `e(ll_0)`, and `e(depvar)` are consistent between two noncomposite models.

Methods and formulas

Let \( L_0 \) and \( L_1 \) be the log-likelihood values associated with the full and constrained models, respectively. The test statistic of the likelihood-ratio test is \( LR = -2(L_1 - L_0) \). If the constrained model is true, \( LR \) is approximately \( \chi^2 \) distributed with \( d_0 - d_1 \) degrees of freedom, where \( d_0 \) and \( d_1 \) are the model degrees of freedom associated with the full and constrained models, respectively (Greene 2012, 526–527).

`lrtest` determines the degrees of freedom of a model as the rank of e(V), computed as the number of nonzero diagonal elements of `invsym(e(V))`.

**lsens — Graph sensitivity and specificity versus probability cutoff**

**Description**

`lsens` graphs sensitivity and specificity versus probability cutoff and optionally creates new variables containing these data.

`lsens` requires that the current estimation results be from `logistic`, `logit`, `probit`, or `ivprobit`; see [R] `logistic`, [R] `logit`, [R] `probit`, or [R] `ivprobit`.

**Quick start**

Graph sensitivity and specificity versus a probability cutoff using current estimation results

```
lsens
```

Generate variables `v1`, `v2`, and `v3` to contain probability cutoffs, sensitivity, and specificity

```
lsens, genprob(v1) gensens(v2) genspec(v3)
```

Add “My Title” to graph

```
lsens, genprob(v1) gensens(v2) genspec(v3) title(My Title)
```

**Menu**

Statistics > Binary outcomes > Postestimation > Sensitivity/specificity plot
lsens — Graph sensitivity and specificity versus probability cutoff

Syntax

```

```

add other plots to the generated graph

Y axis, X axis, Titles, Legend, Overall

```
twoway_options
```

any options other than by() documented in [G-3] twoway_options

Weights are allowed; see [U] 11.1.6 weight.

lsens is not appropriate after the svy prefix.

Options

Main

all requests that the statistic be computed for all observations in the data, ignoring any if or in restrictions specified by the estimation command.

genprob(varname), gensens(varname), and genspec(varname) specify the names of new variables created to contain, respectively, the probability cutoffs and the corresponding sensitivity and specificity.

replace requests that existing variables specified for genprob(), gensens(), or genspec() be overwritten.

nograph suppresses graphical output.

Advanced

beta(matname) specifies a row vector containing model coefficients. The columns of the row vector must be labeled with the corresponding names of the independent variables in the data. The dependent variable depvar must be specified immediately after the command name. See Models other than the last fitted model later in this entry.
Plot

CONNECT_OPTIONS affect the rendition of the plotted points connected by lines; see CONNECT_OPTIONS in [G-2] GRAPH TWOWAY SCATTER.

Add plots

ADD_PLOT(plot) provides a way to add other plots to the generated graph. See [G-3] ADD_PLOT_OPTION.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] TWOWAY_OPTIONS, excluding by(). These include options for titling the graph (see [G-3] TITLE_OPTIONS) and for saving the graph to disk (see [G-3] SAVING_OPTION).

Remarks and examples

Remarks are presented under the following headings:

Introduction
Models other than the last fitted model

Introduction

lsens plots sensitivity and specificity; it plots both sensitivity and specificity versus probability cutoff c. The graph is equivalent to what you would get from estat classification (see [R] estat classification) if you varied the cutoff probability c from 0 to 1.

Example 1

We illustrate lsens after logistic; see [R] logistic.

. use http://www.stata-press.com/data/r14/lbw
   (Hosmer & Lemeshow data)
. logistic low age i.race smoke ui
   (output omitted)
. lsens

![Graph of sensitivity and specificity versus probability cutoff]
lsens optionally creates new variables containing the probability cutoff, sensitivity, and specificity.

```
lsens, genprob(p) gensens(sens) genspec(spec) nograph
```

The variables created will have $M + 2$ distinct nonmissing values: one for each of the $M$ covariate patterns, one for $c = 0$, and another for $c = 1$. Values are recorded for $p = 0$, for each of the observed predicted probabilities, and for $p = 1$. The total number of observations required to do this can be fewer than $\_N$, the same as $\_N$, or $\_N + 1$, or $\_N + 2$. If more observations are added, they are added at the end of the dataset and the values of the original variables are set to missing in the added observations. How the values added align with existing observations is irrelevant.

### Technical note

`logistic`, `logit`, `probit`, or `ivprobit` and `lsens` keep track of the estimation sample. If you type, for instance, `logistic ... if x==1`, then when you type `lsens`, the statistics will be calculated on the `x==1` subsample of the data automatically.

You should specify `if` or `in` with `lsens` only when you wish to produce graphs and calculate statistics for a set of observations other than the estimation sample.

If the `logistic` model was fit with `fweights`, `lsens` properly accounts for the weights in its calculations. You do not have to specify the weights when you run `lsens`. Weights should be specified with `lsens` only when you wish to use a different set of weights.

### Models other than the last fitted model

By default, `lsens` uses the last model fit. You may also directly specify the model to `lsens` by inputting a vector of coefficients with the `beta()` option and passing the name of the dependent variable `depvar` to `lsens`.

#### Example 2

Suppose that someone publishes the following logistic model of low birthweight:

$$
Pr(\text{low} = 1) = F(-0.02 \text{age} - 0.01 \text{lwt} + 1.3 \text{black} + 1.1 \text{smoke} + 0.5 \text{ptl} + 1.8 \text{ht} + 0.8 \text{ui} + 0.5)
$$

where $F$ is the cumulative logistic distribution. These coefficients are not odds ratios; they are the equivalent of what `logit` produces.

We can see whether this model fits our data. First we enter the coefficients as a row vector and label its columns with the names of the independent variables plus `cons` for the constant (see [P] matrix define and [P] matrix rownames).

```
. use http://www.stata-press.com/data/r14/lbw3, clear
(Hosmer & Lemeshow data)
. matrix input b = (-0.02, -.01, 1.3, 1.1, .5, 1.8, .8, .5)
. matrix colnames b = age lwt black smoke ptl ht ui _cons
```
We can use `lroc` (see [R] `lroc`) to examine the predictive ability of the model:

```
. lroc low, beta(b) nograph
Logistic model for low
number of observations = 189
area under ROC curve = 0.7275
```

The area under the curve indicates that this model does have some predictive power. We can obtain a graph of sensitivity and specificity as a function of the cutoff probability by typing

```
. lsens low, beta(b)
```

![Graph of sensitivity and specificity](image)

**Stored results**

`lsens` stores the following in `r()`:

- Scalars
  - `r(N)` number of observations

**Methods and formulas**

Let $j$ index observations and $c$ be the cutoff probability. Let $p_j$ be the predicted probability of a positive outcome and $y_j$ be the actual outcome, which we will treat as 0 or 1, although Stata treats it as 0 and non-0, excluding missing observations.

A prediction is classified as *positive* if $p_j \geq c$ and otherwise is classified as *negative*. The classification is *correct* if it is *positive* and $y_j = 1$ or if it is *negative* and $y_j = 0$.

*Sensitivity* is the fraction of $y_j = 1$ observations that are correctly classified. *Specificity* is the percentage of $y_j = 0$ observations that are correctly classified.

Description

`lv` shows a letter-value display (Tukey 1977, 44–49; Hoaglin 1983) for each variable in `varlist`. If no variables are specified, letter-value displays are shown for each numeric variable in the data.

Quick start

Letter-value display for all numeric variables in the dataset

```
  lv
```

Letter-value display for `v1`

```
  lv v1
```

Also generate new variables `_mid`, `_spread`, `_psigma`, and `_z2` containing midsummaries, spreads, pseudosigmas, and $z^2$ values

```
  lv v1, generate
```

Letter-value displays for `v1` separately for each value of `v2`

```
  bysort v2: lv v1
```

Menu

Statistics > Summaries, tables, and tests > Distributional plots and tests > Letter-value display
Syntax

```
lv [varlist] [if] [in] [ , generate tail(#) ]
```

by is allowed; see [D] by.

Options

generate adds four new variables to the data: _mid, containing the midsummaries; _spread, containing the spreads; _psigma, containing the pseudosigmas; and _z2, containing the squared values from a standard normal distribution corresponding to the particular letter value. If the variables _mid, _spread, _psigma, and _z2 already exist, their contents are replaced. At most, only the first 11 observations of each variable are used; the remaining observations contain missing. If varlist specifies more than one variable, the newly created variables contain results for the last variable specified. The generate option may not be used with the by prefix.

tail(#) indicates the inverse of the tail density through which letter values are to be displayed: 2 corresponds to the median (meaning half in each tail), 4 to the fourths (roughly the 25th and 75th percentiles), 8 to the eighths, and so on. # may be specified as 4, 8, 16, 32, 64, 128, 256, 512, or 1,024 and defaults to a value of # that has corresponding depth just greater than 1. The default is taken as 1,024 if the calculation results in a number larger than 1,024. Given the intelligent default, this option is rarely specified.

Remarks and examples

Letter-value displays are a collection of observations drawn systematically from the data, focusing especially on the tails rather than the middle of the distribution. The displays are called letter-value displays because letters have been (almost arbitrarily) assigned to tail densities:

<table>
<thead>
<tr>
<th>Letter</th>
<th>Tail area</th>
<th>Letter</th>
<th>Tail area</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>1/2</td>
<td>B</td>
<td>1/64</td>
</tr>
<tr>
<td>F</td>
<td>1/4</td>
<td>A</td>
<td>1/128</td>
</tr>
<tr>
<td>E</td>
<td>1/8</td>
<td>Z</td>
<td>1/256</td>
</tr>
<tr>
<td>D</td>
<td>1/16</td>
<td>Y</td>
<td>1/512</td>
</tr>
<tr>
<td>C</td>
<td>1/32</td>
<td>X</td>
<td>1/1024</td>
</tr>
</tbody>
</table>
Example 1

We have data on the mileage ratings of 74 automobiles. To obtain a letter-value display, we type

```
. use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
. lv mpg
```

<table>
<thead>
<tr>
<th>M</th>
<th>37.5</th>
<th>F</th>
<th>19</th>
<th>18</th>
<th>21.5</th>
<th>25</th>
<th>7</th>
<th>5.216359</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>10</td>

</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
<td></td>
<td>12</td>
<td>26.5</td>
<td>41</td>
<td>29</td>
<td>6.16562</td>
</tr>
</tbody>
</table>

The decimal points can be made to line up and thus the output made more readable by specifying a display format for the variable; see [U] 12.5 Formats: Controlling how data are displayed.

```
. format mpg %9.2f
. lv mpg
```

At the top, the number of observations is indicated as 74. The first line shows the statistics associated with M, the letter value that puts half the density in each tail, or the median. The median has depth 37.5 (that is, in the ordered data, M is 37.5 observations in from the extremes) and has value 20. The next line shows the statistics associated with F or the fourths. The fourths have depth 19 (that is, in the ordered data, the lower fourth is observation 19, and the upper fourth is observation 74 − 19 + 1), and the values of the lower and upper fourths are 18 and 25. The number in the middle is the point halfway between the fourths—called a midsummary. If the distribution were perfectly symmetric, the midsummary would equal the median. The spread is the difference between the lower and upper summaries (25 − 18 = 7). For fourths, half the data lie within a 7-mpg band. The pseudosigma is a calculation of the standard deviation using only the lower and upper summaries and assuming that the variable is normally distributed. If the data really were normally distributed, all the pseudosigmas would be roughly equal.

After the letter values, the line labeled with depth 1 reports the minimum and maximum values. Here the halfway point between the extremes is 26.5, which is greater than the median, indicating that 41 is more extreme than 12, at least relative to the median. And with each letter value, the midsummaries are increasing—our data are skewed. The pseudosigmas are also increasing, indicating
that the data are spreading out relative to a normal distribution, although, given the evident skewness, this elongation may be an artifact of the skewness.

At the end is an attempt to identify outliers, although the points so identified are merely outside some predetermined cutoff. Points outside the inner fence are called outside values or mild outliers. Points outside the outer fence are called severe outliers. The inner fence is defined as $(3/2)\text{IQR}$ and the outer fence as $3\text{IQR}$ above and below the $F$ summaries, where the interquartile range (IQR) is the spread of the fourths.

Technical note

The form of the letter-value display has varied slightly with different authors. lv displays appear as described by Hoaglin (1983) but as modified by Emerson and Stoto (1983), where they included the midpoint of each of the spreads. This format was later adopted by Hoaglin (1985). If the distribution is symmetric, the midpoints will all be roughly equal. On the other hand, if the midpoints vary systematically, the distribution is skewed.

The pseudosigmas are obtained from the lower and upper summaries for each letter value. For each letter value, they are the standard deviation a normal distribution would have if its spread for the given letter value were to equal the observed spread. If the pseudosigmas are all roughly equal, the data are said to have neutral elongation. If the pseudosigmas increase systematically, the data are said to be more elongated than a normal, that is, have thicker tails. If the pseudosigmas decrease systematically, the data are said to be less elongated than a normal, that is, have thinner tails.

Interpretation of the number of mild and severe outliers is more problematic. The following discussion is drawn from Hamilton (1991):

Obviously, the presence of any such outliers does not rule out that the data have been drawn from a normal distribution; in large datasets, there will most certainly be observations outside $(3/2)\text{IQR}$ and $3\text{IQR}$. Severe outliers, however, make up about two per million (0.0002%) of a normal population. In samples, they lie far enough out to have substantial effects on means, standard deviations, and other classical statistics. The 0.0002%, however, should be interpreted carefully; outliers appear more often in small samples than one might expect from population proportions because of sampling variation in estimated quartiles. Monte Carlo simulation by Hoaglin, Iglewicz, and Tukey (1986) obtained these results on the percentages and numbers of outliers in random samples from a normal population:

<table>
<thead>
<tr>
<th>n</th>
<th>percentage any outliers</th>
<th>severe</th>
<th>number any outliers</th>
<th>severe</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>2.83</td>
<td>.362</td>
<td>.283</td>
<td>.0362</td>
</tr>
<tr>
<td>20</td>
<td>1.66</td>
<td>.074</td>
<td>.332</td>
<td>.0148</td>
</tr>
<tr>
<td>50</td>
<td>1.15</td>
<td>.011</td>
<td>.575</td>
<td>.0055</td>
</tr>
<tr>
<td>100</td>
<td>.95</td>
<td>.002</td>
<td>.95</td>
<td>.002</td>
</tr>
<tr>
<td>200</td>
<td>.79</td>
<td>.001</td>
<td>1.58</td>
<td>.002</td>
</tr>
<tr>
<td>300</td>
<td>.75</td>
<td>.001</td>
<td>2.25</td>
<td>.003</td>
</tr>
<tr>
<td>∞</td>
<td>.70</td>
<td>.0002</td>
<td>∞</td>
<td>∞</td>
</tr>
</tbody>
</table>

Thus the presence of any severe outliers in samples of less than 300 is sufficient to reject normality. Hoaglin, Iglewicz, and Tukey (1981) suggested the approximation $0.00698 + 0.4/n$ for the fraction of mild outliers in a sample of size $n$ or, equivalently, $0.00698n + 0.4$ for the number of outliers.
Example 2

The `generate` option adds the `_mid`, `_spread`, `_psigma`, and `_z2` variables to our data, making possible many of the diagnostic graphs suggested by Hoaglin (1985).

```
. lv mpg, generate
(output omitted)
. list _mid _spread _psigma _z2 in 1/12

<table>
<thead>
<tr>
<th>_mid</th>
<th>_spread</th>
<th>_psigma</th>
<th>_z2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>20</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2.</td>
<td>11.5</td>
<td>7</td>
<td>5.216359</td>
</tr>
<tr>
<td>3.</td>
<td>11.5</td>
<td>13</td>
<td>5.771728</td>
</tr>
<tr>
<td>4.</td>
<td>22.25</td>
<td>16.5</td>
<td>5.576303</td>
</tr>
<tr>
<td>5.</td>
<td>23.5</td>
<td>21</td>
<td>5.831039</td>
</tr>
<tr>
<td>6.</td>
<td>23.5</td>
<td>23</td>
<td>5.732448</td>
</tr>
<tr>
<td>7.</td>
<td>25</td>
<td>26</td>
<td>6.040635</td>
</tr>
<tr>
<td>8.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>9.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>10.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>11.</td>
<td>26.5</td>
<td>29</td>
<td>6.16562</td>
</tr>
<tr>
<td>12.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Observations 12 through the end are missing for these new variables. The definition of the observations is always the same. The first observation contains the M summary; the second, the F; the third, the E; and so on. Observation 11 always contains the summary for depth 1. Observations 8–10—corresponding to letter values Z, Y, and X—contain missing because these statistics were not calculated. We have only 74 observations, and their depth would be 1.

Hoaglin (1985) suggests graphing the midsummary against $z^2$. If the distribution is not skewed, the points in the resulting graph will be along a horizontal line:

```
. scatter _mid _z2
```

The graph clearly indicates the skewness of the distribution. We might also graph `_psigma` against `_z2` to examine elongation.
Stored results

`lv` stores the following in `r()`:

Scalars

<table>
<thead>
<tr>
<th><code>r(N)</code></th>
<th>number of observations</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>r(u_C)</code></td>
<td>upper 32nd</td>
</tr>
<tr>
<td><code>r(l_C)</code></td>
<td>lower 32nd</td>
</tr>
<tr>
<td><code>r(u_B)</code></td>
<td>upper 64th</td>
</tr>
<tr>
<td><code>r(l_B)</code></td>
<td>lower 64th</td>
</tr>
<tr>
<td><code>r(u_A)</code></td>
<td>upper 128th</td>
</tr>
<tr>
<td><code>r(l_A)</code></td>
<td>lower 128th</td>
</tr>
<tr>
<td><code>r(u_Z)</code></td>
<td>upper 256th</td>
</tr>
<tr>
<td><code>r(l_Z)</code></td>
<td>lower 256th</td>
</tr>
<tr>
<td><code>r(u_Y)</code></td>
<td>upper 512th</td>
</tr>
<tr>
<td><code>r(l_Y)</code></td>
<td>lower 512th</td>
</tr>
<tr>
<td><code>r(u_E)</code></td>
<td>upper 1024th</td>
</tr>
<tr>
<td><code>r(l_E)</code></td>
<td>lower 1024th</td>
</tr>
<tr>
<td><code>r(u_X)</code></td>
<td>upper 1024th</td>
</tr>
<tr>
<td><code>r(l_X)</code></td>
<td>lower 1024th</td>
</tr>
</tbody>
</table>

The lower/upper 8ths, 16ths, ..., 1024ths will be defined only if there are sufficient data.

Methods and formulas

Let $N$ be the number of (nonmissing) observations on $x$, and let $x(i)$ refer to the ordered data when $i$ is an integer. Define $x(i+0.5) = (x(i) + x(i+1))/2$; the median is defined as $x\{(N+1)/2\}$.

Define $x[d]$ as the pair of numbers $x(d)$ and $x(N+1-d)$, where $d$ is called the depth. Thus $x[1]$ refers to the minimum and maximum of the data. Define $m = (N+1)/2$ as the depth of the median, $f = (\lfloor m \rfloor + 1)/2$ as the depth of the fourths, $e = (\lfloor f \rfloor + 1)/2$ as the depth of the eighths, and so on. Depths are reported on the far left of the letter-value display. The corresponding fourths of the data are $x[f]$, the eighths are $x[e]$, and so on. These values are reported inside the display. The middle value is defined as the corresponding midpoint of $x[\cdot]$. The spreads are defined as the difference in $x[\cdot]$.

The corresponding point $z_i$ on a standard normal distribution is obtained as (Hoaglin 1985, 456–457)

$$z_i = \begin{cases} F^{-1}\{(d_i - 1/3)/(N + 1/3)\} & \text{if } d_i > 1 \\ F^{-1}\{0.695/(N + 0.390)\} & \text{otherwise} \end{cases}$$

where $d_i$ is the depth of the letter value. The corresponding pseudosigma is obtained as the ratio of the spread to $-2z_i$ (Hoaglin 1985, 431).

Define $(F_l, F_u) = x[f]$. The inner fence has cutoffs $F_l - \frac{3}{2}(F_u - F_l)$ and $F_u + \frac{3}{2}(F_u - F_l)$. The outer fence has cutoffs $F_l - 3(F_u - F_l)$ and $F_u + 3(F_u - F_l)$.

The inner-fence values reported by `lv` are almost equal to those used by `graph`. The only difference is that `graph` uses a slightly different definition of fourths, namely, the 25th and 75th percentiles as defined by `summarize`; see [R] `summarize`.

[R] summarize — Summary statistics
Margins are statistics calculated from predictions of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates.

The margins command estimates margins of responses for specified values of covariates and presents the results as a table.

Capabilities include estimated marginal means, least-squares means, average and conditional marginal and partial effects (which may be reported as derivatives or as elasticities), average and conditional adjusted predictions, and predictive margins.

Quick start

Estimated marginal means (least-squares means)

Estimated marginal mean of \( y \) for each level of \( a \) after \texttt{anova y a##b}

\begin{verbatim}
 margins a, asbalanced
\end{verbatim}

Estimated marginal mean of \( y \) for each level of the interaction of \( a \) and \( b \) after \texttt{anova y a##b##c}

\begin{verbatim}
 margins a#b, asbalanced
\end{verbatim}

Estimated marginal means of \( y_1 \), \( y_2 \), and \( y_3 \) for each level of \( a \) after \texttt{manova y1 y2 y3 = a##b}

\begin{verbatim}
 margins a, asbalanced
\end{verbatim}

Adjusted means and adjusted predictions

Adjusted mean of \( y \) for each level of \( a \) when \( x \) is at its mean after \texttt{regress y i.a x}

\begin{verbatim}
 margins a, atmeans
\end{verbatim}

As above, but set \( x \) to 10 rather than to its mean

\begin{verbatim}
 margins a, at(x=10)
\end{verbatim}

As above, and also report adjusted means for \( x = 20 \), \( x = 30 \), and \( x = 40 \)

\begin{verbatim}
 margins a, at(x=(10(10)40))
\end{verbatim}

Adjusted predicted probability of \( y = 1 \) for each level of \( a \) when \( x \) is at its mean after \texttt{logit y a##c.x}

\begin{verbatim}
 margins a, atmeans
\end{verbatim}

Adjusted predicted probability for each level of the interaction of \( a \) and \( b \), holding \( x \) at 25, after \texttt{logit y a##b##c.x}

\begin{verbatim}
 margins a#b, at(x=25)
\end{verbatim}

Adjusted prediction for each level of \( a \) when \( x = 25 \) and \( b = 1 \)

\begin{verbatim}
 margins a, at(x=25 b=1)
\end{verbatim}
Predictive margins and potential-outcome means

Overall predictive margin, the average predicted probability of \( y = 1 \), after \( \logit y \ a##b \ x1 \ x2 \)

Predictive margins (potential-outcome means) for each level of \( a \)

Predictive margins for \( a \), when \( x1 \) is set to 10, 20, 30, and 40

\[
\text{margins} \ a, \ \text{at}(x1=(10(10)40))
\]

Predictive margins for levels of the interaction of \( a \) and \( b \)

\[
\text{margins} \ a#b
\]

Predictive margins for \( a \) for all combinations of \( x1 = 10, 20, 30 \) and \( x2 = 50, 100, 150 \)

\[
\text{margins} \ a, \ \text{at}(x1=(10(10)30) \ x2=(50(50)150))
\]

Predictive margins for \( a \), first for \( x1 = 10, 20, 30 \) with \( x2 \) at its observed values, then for \( x2 = 50, 100, 150 \) with \( x1 \) at its observed values

\[
\text{margins} \ a, \ \text{at}(x1=(10(10)30)) \ \text{at}(x2=(50(50)150))
\]

Predictive margins for \( a \) after \( \text{svy:logit} \ y \ a##b \ x1 \ x2 \)

\[
\text{margins} \ a, \ \text{vce}(\text{unconditional})
\]

Average predicted probabilities of \( y = 1, y = 2, \ldots \) after \( \text{mlogit} \ y \ x1 \ x2 \ i.a \)

Predictive margins for each level of \( a \) for each outcome of \( y \)

\[
\text{margins} \ a
\]

Average marginal effects and average partial effects

Average marginal effect of \( x1 \) on the predicted probability of \( y = 1 \) after \( \text{probit} \ y \ c.x1##c.x2##a \) with continuous \( x1 \) and \( x2 \) and binary \( a \)

\[
\text{margins}, \ \text{dydx}(x1)
\]

Average marginal effect (average partial effect) of binary \( a \)

\[
\text{margins}, \ \text{dydx}(a)
\]

Average marginal effect of \( x1 \) when \( x2 \) is set to 10, 20, 30, and 40

\[
\text{margins}, \ \text{dydx}(x1) \ \text{at}(x2=(10(10)40))
\]

Average marginal effect of \( x1 \) when \( a \) is set to 0 and then to 1

\[
\text{margins} \ a, \ \text{dydx}(x1)
\]

Average marginal effect of each variable in the model

\[
\text{margins}, \ \text{dydx}(*)
\]

Average marginal effect of all variables on the truncated expected value of \( y, \ e(0,.), \) after \( \text{tobit} \ y \ x1 \ x2 \ x3, \ ll(0) \)

\[
\text{margins}, \ \text{dydx}(*) \ \text{predict}(e(0,.))
\]
As above, and report marginal effects for censored expected value of y, ystar(0,.), and for the linear prediction, xb

margins, dydx(*) predict(e(0,.)) predict(ystar(0,.)) predict(xb)

Conditional marginal effects and conditional partial effects

Marginal effect of x1 on the predicted probability of y = 1, setting all variables to their means, after probit y c.x1##c.x2##a with continuous x1 and x2 and binary a

margins, dydx(x1) atmeans

Marginal effect (partial effect) of a when all variables are set to their means

margins, dydx(a) atmeans

Marginal effect of x1 when a = 0 and x1 and x2 are set to their means

margins, dydx(x1) at(a=0 (mean) x1 x2)

Same as above

margins, dydx(x1) at(a=0) atmeans

Marginal effect of x1 when for all possible combinations of a = 0, 1, x1 = 50, 100, and x2 = 10, 20, 30, 40

margins a, dydx(x1) at(x1=(50 100) x2=(10(10)40))

Marginal effects of x1, x2, and a with all variables set to their means

margins, dydx(*) atmeans

Menu

Statistics > Postestimation

Syntax

margins [marginlist] [if] [in] [weight] [, response_options options]

where marginlist is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without the i. prefix, and you may use any factor-variable syntax:

. margins i.sex i.group i.sex#i.group
. margins sex group sex#i.group
. margins sex##group

response_options Description

Main

_predict(pred_opt) estimate margins for predict, pred_opt
expre(expression(pnl_exp) estimate margins for pnl_exp
dydx(varlist) estimate marginal effect of variables in varlist
eyex(varlist) estimate elasticities of variables in varlist
dyex(varlist) estimate semielasticity—d(y)/d(lnx)
eydx(varlist) estimate semielasticity—d(lny)/d(x)
continuous treat factor-level indicators as continuous
### Main
- **grand**
  - add the overall margin; default if no `marginlist`

### At
- **at**(`atspec`)
  - estimate margins at specified values of covariates
- **atmeans**
  - estimate margins at the means of covariates
- **asbalanced**
  - treat all factor variables as balanced

### if/in/over
- **over**(`varlist`)
  - estimate margins at unique values of `varlist`
- **subpop**(`subspec`)
  - estimate margins for subpopulation

### Within
- **within**(`varlist`)
  - estimate margins at unique values of the nesting factors in `varlist`

### Contrast
- **contrast_options**
  - any options documented in [R] `margins, contrast`

### Pairwise comparisons
- **pwcompare_options**
  - any options documented in [R] `margins, pwcompare`

### SE
- **vce(delta)**
  - estimate SEs using delta method; the default
- **vce(unconditional)**
  - estimate SEs allowing for sampling of covariates
- **nose**
  - do not estimate SEs

### Advanced
- **noweight**
  - ignore weights specified in estimation
- **noesample**
  - do not restrict margins to the estimation sample
- **emptycells**(`empspec`)
  - treatment of empty cells for balanced factors
- **estimtolerance**(`tol`)
  - specify numerical tolerance used to determine estimable functions; default is `estimtolerance(1e-5)`
- **noestimcheck**
  - suppress estimability checks
- **force**
  - estimate margins despite potential problems
- **chainrule**
  - use the chain rule when computing derivatives
- **nochainrule**
  - do not use the chain rule

### Reporting
- **level(#)**
  - set confidence level; default is `level(95)`
- **mcompare**(`method`)
  - adjust for multiple comparisons; default is `mcompare(noadjust)`
- **noatlegend**
  - suppress legend of fixed covariate values
- **post**
  - post margins and their VCE as estimation results
  - `display_options`
    - control columns and column formats, row spacing, line width and factor-variable labeling
- **df(#)**
  - use t distribution with # degrees of freedom for computing p-values and confidence intervals
method               | Description               |
---------------------|---------------------------|
noadjust            | do not adjust for multiple comparisons; the default |
bonferroni [adjustall] | Bonferroni’s method; adjust across all terms |
sidak [adjustall] | Šidák’s method; adjust across all terms |
scheffe             | Scheffé’s method |

Time-series operators are allowed if they were used in the estimation. See `at()` under Options for a description of `atspec`.

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

df(#) does not appear in the dialog box.

Options

Warning: The option descriptions are brief and use jargon. Skip to Remarks and examples if you are reading about margins for the first time.

(predict(pred_opt) and expression(pnl_exp) are mutually exclusive; they specify the response. If neither is specified, the response will be the default prediction that would be produced by predict after the underlying estimation command. Some estimation commands, such as mlogit, document a different default prediction for margins than for predict.

predict(pred_opt) specifies the option(s) to be specified with the predict command to produce the variable that will be used as the response. After estimation by logistic, you could specify predict(xb) to obtain linear predictions rather than the predict command’s default, the probabilities.

Multiple predict() options can be specified to compute margins of multiple predictions simultaneously.

expression(pnl_exp) specifies the response as an expression. See [R] predictnl for a full description of pnl_exp. After estimation by logistic, you might specify expression(exp(predict(xb)))) to use relative odds rather than probabilities as the response. For examples, see Example 12: Margins of a specified expression.

dydx(varlist), eyex(varlist), dyex(varlist), and eydx(varlist) request that margins report derivatives of the response with respect to varlist rather than on the response itself. eyex(), dyex(), and eydx() report derivatives as elasticities; see Expressing derivatives as elasticities.

continuous is relevant only when one of dydx() or eydx() is also specified. It specifies that the levels of factor variables be treated as continuous; see Derivatives versus discrete differences. This option is implied if there is a single-level factor variable specified in dydx() or eydx().

grand specifies that the overall margin be reported. grand is assumed when marginlist is empty.

at(atspec) specifies values for covariates to be treated as fixed.

at(age=20) fixes covariate age to the value specified. at() may be used to fix continuous or factor covariates.

at(age=20 sex=1) simultaneously fixes covariates age and sex at the values specified.
margins — Marginal means, predictive margins, and marginal effects

at(age=(20 30 40 50)) fixes age first at 20, then at 30, .... margins produces separate results for each specified value.

at(age=(20(10)50)) does the same as at(age=(20 30 40 50)); that is, you may specify a numlist.

at((mean) age (median) distance) fixes the covariates at the summary statistics specified.

at((p25) _all) fixes all covariates at their 25th percentile values. See Syntax of at() for the full list of summary-statistic modifiers.

at((mean) _all (median) x x2=1.2 z=(1 2 3)) is read from left to right, with latter specifiers overriding former ones. Thus all covariates are fixed at their means except for x (fixed at its median), x2 (fixed at 1.2), and z (fixed first at 1, then at 2, and finally at 3).

at((means) _all (asobserved) x2) is a convenient way to set all covariates except x2 to the mean.

Multiple at() options can be specified, and each will produce a different set of margins.

See Syntax of at() for more information.

atmeans specifies that covariates be fixed at their means and is shorthand for at((mean) _all). atmeans differs from at((mean) _all) in that atmeans will affect subsequent at() options. For instance,

.margins ..., atmeans at((p25) x) at((p75) x)

produces two sets of margins with both sets evaluated at the means of all covariates except x.

asbalanced is shorthand for at((asbalanced) _factor) and specifies that factor covariates be evaluated as though there were an equal number of observations in each level; see Obtaining margins as though the data were balanced. asbalanced differs from at((asbalanced) _factor) in that asbalanced will affect subsequent at() options in the same way as atmeans does.

over(varlist) specifies that separate sets of margins be estimated for the groups defined by varlist. The variables in varlist must contain nonnegative integer values. The variables need not be covariates in your model. When over() is combined with the vce(unconditional) option, each group is treated as a subpopulation; see [SVY] subpopulation estimation.

subpop([varname] [if]) is intended for use with the vce(unconditional) option. It specifies that margins be estimated for the single subpopulation identified by the indicator variable or by the if expression or by both. Zero indicates that the observation be excluded; nonzero, that it be included; and missing value, that it be treated as outside of the population (and so ignored). See [SVY] subpopulation estimation for why subpop() is preferred to if expressions and in ranges when also using vce(unconditional). If subpop() is used without vce(unconditional), it is treated merely as an additional if qualifier.

within(varlist) allows for nested designs. varlist contains the nesting variable(s) over which margins are to be estimated. See Obtaining margins with nested designs. As with over(varlist), when within(varlist) is combined with vce(unconditional), each level of the variables in varlist is treated as a subpopulation.

contrast_options are any of the options documented in [R] margins, contrast.
Pairwise comparisons

`pwcompare_options` are any of the options documented in [R] margins, pwcompare.

**SE**

`vce(delta)` and `vce(unconditional)` specify how the VCE and, correspondingly, standard errors are calculated.

`vce(delta)` is the default. The delta method is applied to the formula for the response and the VCE of the estimation command. This method assumes that values of the covariates used to calculate the response are given or, if all covariates are not fixed using `at()`, that the data are given.

`vce(unconditional)` specifies that the covariates that are not fixed be treated in a way that accounts for their having been sampled. The VCE is estimated using the linearization method. This method allows for heteroskedasticity or other violations of distributional assumptions and allows for correlation among the observations in the same manner as `vce(robust)` and `vce(cluster ...)`, which may have been specified with the estimation command. This method also accounts for complex survey designs if the data are `svyset`. See Obtaining margins with survey data and representative samples. When you use complex survey data, this method requires that the linearized variance estimation method be used for the model. See [SVY] svy postestimation for an example of `margins` with replication-based methods.

`nose` suppresses calculation of the VCE and standard errors. See Requirements for model specification for an example of the use of this option.

**Advanced**

`noweights` specifies that any weights specified on the previous estimation command be ignored by `margins`. By default, `margins` uses the weights specified on the estimator to average responses and to compute summary statistics. If weights are specified on the `margins` command, they override previously specified weights, making it unnecessary to specify `noweights`. The `noweights` option is not allowed after `svy: estimation` when the `vce(unconditional)` option is specified.

For multilevel models, such as `meglm`, the default behavior is to construct a single weight value for each observation by multiplying the corresponding multilevel weights within the given observation.

`noesample` specifies that `margins` not restrict its computations to the estimation sample used by the previous estimation command. See Example 15: Margins evaluated out of sample.

With the default delta-method VCE, `noesample` margins may be estimated on samples other than the estimation sample; such results are valid under the assumption that the data used are treated as being given.

You can specify `noesample` and `vce(unconditional)` together, but if you do, you should be sure that the data in memory correspond to the original `e(sample)`. To show that you understand that, you must also specify the `force` option. Be aware that making the `vce(unconditional)` calculation on a sample different from the estimation sample would be equivalent to estimating the coefficients on one set of data and computing the scores used by the linearization on another set; see [P] _robust.

`emptycells(strict)` and `emptycells(reweight)` are relevant only when the `asbalanced` option is also specified. `emptycells()` specifies how empty cells are handled in interactions involving factor variables that are being treated as balanced; see Obtaining margins as though the data were balanced.

`emptycells(strict)` is the default; it specifies that margins involving empty cells be treated as not estimable.
emptycells(reweight) specifies that the effects of the observed cells be increased to accommodate any missing cells. This makes the margin estimable but changes its interpretation. emptycells(reweight) is implied when the within() option is specified.

estimtolerance(tol) specifies the numerical tolerance used to determine estimable functions. The default is estimtolerance(1e-5).

A linear combination of the model coefficients $z$ is found to be not estimable if

\[ \text{mreldif}(z, z \times H) > tol \]

where $H$ is defined in Methods and formulas.

noestimcheck specifies that margins not check for estimability. By default, the requested margins are checked and those found not estimable are reported as such. Nonestimability is usually caused by empty cells. If noestimcheck is specified, estimates are computed in the usual way and reported even though the resulting estimates are manipulable, which is to say they can differ across equivalent models having different parameterizations. See Estimability of margins.

force instructs margins to proceed in some situations where it would otherwise issue an error message because of apparent violations of assumptions. Do not be casual about specifying force. You need to understand and fully evaluate the statistical issues. For an example of the use of force, see Using margins after the estimates use command.

chainrule and nochainrule specify whether margins uses the chain rule when numerically computing derivatives. You need not specify these options when using margins after any official Stata estimator; margins will choose the appropriate method automatically.

Specify nochainrule after estimation by a user-written command. We recommend using nochainrule, even though chainrule is usually safe and is always faster. nochainrule is safer because it makes no assumptions about how the parameters and covariates join to form the response.

nochainrule is implied when the expression() option is specified.

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [U] 20.7 Specifying the width of confidence intervals.

mcompare(method) specifies the method for computing $p$-values and confidence intervals that account for multiple comparisons within a factor-variable term.

Most methods adjust the comparisonwise error rate, $\alpha_c$, to achieve a prespecified experimentwise error rate, $\alpha_e$.

mcompare(noadjust) is the default; it specifies no adjustment.

\[ \alpha_c = \alpha_e \]

mcompare(bonferroni) adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality

\[ \alpha_e \leq m\alpha_c \]

where $m$ is the number of comparisons within the term.

The adjusted comparisonwise error rate is

\[ \alpha_c = \frac{\alpha_e}{m} \]
mcompare(sidak) adjusts the comparisonwise error rate based on the upper limit of the probability inequality
\[ \alpha_e \leq 1 - (1 - \alpha_c)^m \]

where \( m \) is the number of comparisons within the term.

The adjusted comparisonwise error rate is
\[ \alpha_c = 1 - (1 - \alpha_e)^{1/m} \]

This adjustment is exact when the \( m \) comparisons are independent.

mcompare(scheffe) controls the experimentwise error rate using the \( F \) or \( \chi^2 \) distribution with degrees of freedom equal to the rank of the term.

mcompare(method adjustall) specifies that the multiple-comparison adjustments count all comparisons across all terms rather than performing multiple comparisons term by term. This leads to more conservative adjustments when multiple variables or terms are specified in marginslist. This option is compatible only with the bonferroni and sidak methods.

noatlegend specifies that the legend showing the fixed values of covariates be suppressed.

post causes margins to behave like a Stata estimation (e-class) command. margins posts the vector of estimated margins along with the estimated variance–covariance matrix to e(), so you can treat the estimated margins just as you would results from any other estimation command. For example, you could use test to perform simultaneous tests of hypotheses on the margins, or you could use lincom to create linear combinations. See Example 10: Testing margins—contrasts of margins.

display_options: noci, nopvalues, vsquish, noflabel, fvwrap(#), fvwrapon(style), cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch.

noci suppresses confidence intervals from being reported in the coefficient table.

nopvalues suppresses \( p \)-values and their test statistics from being reported in the coefficient table.

vsquish specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.

nofvlabel displays factor-variable level values rather than attached value labels. This option overrides the fvlabel setting; see [R] set showbaselevels.

fvwrap(#) allows long value labels to wrap the first # lines in the coefficient table. This option overrides the fvwrap setting; see [R] set showbaselevels.

fvwrapon(style) specifies whether value labels that wrap will break at word boundaries or break based on available space.

fvwrapon(word), the default, specifies that value labels break at word boundaries.

fvwrapon(width) specifies that value labels break based on available space.

This option overrides the fvwrapon setting; see [R] set showbaselevels.

cformat(%,fmt) specifies how to format margins, standard errors, and confidence limits in the table of estimated margins.

pformat(%,fmt) specifies how to format \( p \)-values in the table of estimated margins.

sformat(%,fmt) specifies how to format test statistics in the table of estimated margins.

nolstretch specifies that the width of the table of estimated margins not be automatically widened to accommodate longer variable names. The default, lstretch, is to automatically widen the table of estimated margins up to the width of the Results window. To change the default, use set lstretch off. nolstretch is not shown in the dialog box.
The following option is available with `margins` but is not shown in the dialog box:

`df(#)` specifies that the $t$ distribution with $#$ degrees of freedom be used for computing $p$-values and confidence intervals. The default typically is to use the standard normal distribution. However, if the estimation command computes the residual degrees of freedom (`e(df_r)`) and `predict(xb)` is specified with `margins`, the default is to use the $t$ distribution with $e(df_r)$ degrees of freedom.

Introduction

`margins` is a postestimation command, a command for use after you have fit a model using an estimation command such as `regress` or `logistic`, or using almost any other estimation command.

`margins` estimates and reports margins of responses and margins of derivatives of responses, also known as marginal effects. A margin is a statistic based on a fitted model in which some of or all the covariates are fixed. Marginal effects are changes in the response for change in a covariate, which can be reported as a derivative, elasticity, or semielasticity.

For a brief overview of `margins`, see Williams (2012).

Obtaining margins of responses

What we call margins of responses are also known as predictive margins, adjusted predictions, and recycled predictions. When applied to balanced data, margins of responses are also called estimated marginal means and least-squares means.

A margin is a statistic based on a fitted model calculated over a dataset in which some of or all the covariates are fixed at values different from what they really are. For instance, after a linear regression fit on males and females, the marginal mean (margin of mean) for males is the predicted mean of the dependent variable, where every observation is treated as if it represents a male; thus those observations that in fact do represent males are included, as well as those observations that represent females. The marginal mean for female would be similarly obtained by treating all observations as if they represented females.

In making the calculation, sex is treated as male or female everywhere it appears in the model. The model might be

```
. regress y age bp i.sex sex#c.age sex#c.bp
```

and then, in making the marginal calculation of the mean for males and females, `margins` not only accounts for the direct effect of `i.sex` but also for the indirect effects of `sex#c.age` and `sex#c.bp`.

The response being margined can be any statistic produced by `[R] predict`, or any expression of those statistics.

Standard errors are obtained by the delta method, at least by default. The delta method assumes that the values at which the covariates are evaluated to obtain the marginal responses are fixed. When your sample represents a population, whether you are using `svy` or not (see [SVY] svy), you can specify `margins`’ `vce(unconditional)` option and `margins` will produce standard errors that account for the sampling variability of the covariates. Some researchers reserve the term predictive margins to describe this.

The best way to understand `margins` is to see some examples. You can run the following examples yourself if you type

```
. use http://www.stata-press.com/data/r14/margex
(Artificial data for margins)
```
Example 1: A simple case after `regress`

```
. regress y i.sex i.group
    (output omitted)
. margins sex
```

<table>
<thead>
<tr>
<th>Predictive margins</th>
<th>Number of obs = 3,000</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model VCE</td>
<td>OLS</td>
</tr>
<tr>
<td>Expression</td>
<td>Linear prediction, predict()</td>
</tr>
</tbody>
</table>

| Delta-method | Margin   | Std. Err. | t      | P>|t|   | [95% Conf. Interval] |
|--------------|----------|-----------|--------|-------|---------------------|
| sex          |          |           |        |       |                     |
| male         | 60.56034 | .5781782  | 104.74 | 0.000 | 59.42668            |
| female       | 78.88236 | .5772578  | 136.65 | 0.000 | 77.7505             |

The numbers reported in the “Margin” column are average values of \( y \). Based on a linear regression of \( y \) on sex and group, 60.6 would be the average value of \( y \) if everyone in the data were treated as if they were male, and 78.9 would be the average value if everyone were treated as if they were female.

Example 2: A simple case after `logistic`

```
. logistic outcome i.sex i.group
    (output omitted)
. margins sex
```

<table>
<thead>
<tr>
<th>Predictive margins</th>
<th>Number of obs = 3,000</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model VCE</td>
<td>OIM</td>
</tr>
<tr>
<td>Expression</td>
<td>Pr(outcome), predict()</td>
</tr>
</tbody>
</table>

| Delta-method       | Margin  | Std. Err. | z      | P>|z|    | [95% Conf. Interval] |
|--------------------|---------|-----------|--------|-------|---------------------|
| sex                |         |           |        |       |                     |
| male               | .1286796| .0111424  | 11.55  | 0.000 | .106841             |
| female             | .1905087| .0089719  | 21.23  | 0.000 | .1729241            |

The numbers reported in the “Margin” column are average predicted probabilities. Based on a logistic regression of \( \text{outcome} \) on sex and group, 0.13 would be the average probability of \( \text{outcome} \) if everyone in the data were treated as if they were male, and 0.19 would be the average probability if everyone were treated as if they were female.

`margins` reports average values after `regress` and average probabilities after `logistic`. By default, `margins` makes tables of whatever it is that `predict` (see [R] `predict`) predicts by default. Alternatively, `margins` can make tables of anything that `predict` can produce if you use `margins' predict()` option; see Example 11: Margins of a specified prediction.
Example 3: Average response versus response at average

In example 2, margins reported average probabilities of outcome for \( \text{sex} = 0 \) and \( \text{sex} = 1 \). If we instead wanted the predicted probabilities evaluated at the mean of the covariates, we would specify margins’ atmeans option. We previously typed

```
.logistic outcome i.sex i.group
(output omitted)
.margins sex
(output omitted)
```

and now we type

```
.margins sex, atmeans
```

```
Adjusted predictions       Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
at : 0.sex = .4993333 (mean)
     1.sex = .5006667 (mean)
     1.group = .3996667 (mean)
     2.group = .3726667 (mean)
     3.group = .2276667 (mean)

</tbody>
</table>
```

The prediction at the average of the covariates is different from the average of the predictions. The first is the expected probability of a person with average characteristics, a person who, in another problem, might be 3/4 married and have 1.2 children. The second is the average of the probability among actual persons in the data.

When you specify atmeans or any other at option, margins reports the values used for the covariates in the legend above the table. margins lists the values for all the covariates, including values it may not use, in the results that follow. In this example, margins reported means for sex even though those means were not used. They were not used because we asked for the margins of sex, so sex was fixed first at 0 and then at 1.

If you wish to suppress this legend, specify the nolegend option.

Example 4: Multiple margins from one command

More than one margin can be reported by just one margins command. You can type

```
.margins sex group
```

and doing that is equivalent in terms of the output to typing

```
.margins sex
.margins group
```

When multiple margins are requested on the same command, each is estimated separately. There is, however, a difference when you also specify margins’ post option. Then the variance–covariance matrix for all margins requested is posted, and that is what allows you to test equality of margins, etc. Testing equality of margins is covered in Example 10: Testing margins—contrasts of margins.
In any case, below we request margins for sex and for group.

```
.margins sex group
Predictive margins                                      Number of obs  =  3,000
Model VCE : OIM                                         
Expression : Pr(outcome), predict()
```

|       | Delta-method | Margin  | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|-------|--------------|---------|-----------|------|-----|---------------------|
| sex   |              |         |           |      |     |                     |
| male  |              | .1286796| .0111424  | 11.55| 0.000| .106841 .1505182    |
| female|              | .1905087| .0089719  | 21.23| 0.000| .1729241 .2080933   |
| group |              |         |           |      |     |                     |
| 1     |              | .2826207| .0146234  | 19.33| 0.000| .2539593 .311282    |
| 2     |              | .1074814| .0094901  | 11.33| 0.000| .0888812 .1260817   |
| 3     |              | .0291065| .0073417  | 3.96 | 0.000| .0147169 .043496    |

Example 5: Margins with interaction terms

The estimation command on which margins bases its calculations may contain interaction terms, such as an interaction of sex and group:

```
.logistic outcome i.sex i.group sex#group
(output omitted)
```

```
.margins sex group
Predictive margins                                      Number of obs  =  3,000
Model VCE : OIM                                         
Expression : Pr(outcome), predict()
```

|       | Delta-method | Margin  | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|-------|--------------|---------|-----------|------|-----|---------------------|
| sex   |              |         |           |      |     |                     |
| male  |              | .1561738| .0132774  | 11.76| 0.000| .1301506 .182197    |
| female|              | .1983749| .0101546  | 19.54| 0.000| .1784723 .2182776   |
| group |              |         |           |      |     |                     |
| 1     |              | .3211001| .0176403  | 18.20| 0.000| .2865257 .3566744   |
| 2     |              | .1152127| .0098854  | 11.54| 0.000| .0956417 .1347838   |
| 3     |              | .0265018| .0109802  | 2.41 | 0.016| .0049811 .0480226   |

We fit the model by typing logistic outcome i.sex i.group sex#group, but the meaning would have been the same had we typed logistic outcome sex##group.

As mentioned in example 4, the results for sex and the results for group are calculated independently, and we would have obtained the same results had we typed margins sex followed by margins group.

The margin for male (sex = 0) is 0.16. The probability 0.16 is the average probability if everyone in the data were treated as if sex = 0, including sex = 0 in the main effect and sex = 0 in the interaction of sex with group.

Had we specified margins sex, atmeans, we would have obtained not average probabilities but the probabilities evaluated at the average. Rather than obtaining 0.16, we would have obtained 0.10
for sex = 0. The 0.10 is calculated by taking the fitted model, plugging in sex = 0 everywhere, and plugging in the average value of the group indicator variables everywhere they are used. That is, rather than treating the group indicators as being (1, 0, 0), (0, 1, 0), or (0, 0, 1) depending on observation, the group indicators are treated as being (0.40, 0.37, 0.23), which are the average values of group = 1, group = 2, and group = 3.

Example 6: Margins with continuous variables

To the above example, we will add the continuous covariate age to the model and then rerun margins sex group.

```
. logistic outcome i.sex i.group sex#group age
(output omitted)
. margins sex group
Predictive margins Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
```

|            | Delta-method | Margin | Std. Err. | z     | P>|z| | [95% Conf. Interval] |
|------------|--------------|--------|-----------|-------|-----|---------------------|
| sex        |              |        |           |       |     |                     |
| male       |              | .1600644 | .0125653  | 12.74 | 0.000 | .1354368 .184692    |
| female     |              | .1966902 | .0100043  | 19.66 | 0.000 | .1770821 .2162983   |
| group      |              |         |           |       |     |                     |
| 1          |              | .2251302 | .0123233  | 18.27 | 0.000 | .200977 .2492834    |
| 2          |              | .150603  | .0116505  | 12.93 | 0.000 | .1277685 .1734376   |
| 3          |              | .0736157 | .0337256  | 2.18  | 0.029 | .0075147 .1397167   |

Compared with the results presented in example 5, results for sex change little, but results for groups 1 and 3 change markedly. The tables differ because now we are adjusting for the continuous covariate age, as well as for sex and group.

We will continue examining interactions in example 8. Because we have added a continuous variable, let’s take a detour to explain how to obtain margins for continuous variables and to explain their interpretation.

Example 7: Margins of continuous variables

Continuing with our example of

```
. logistic outcome i.sex i.group sex#group age
```

let’s examine the continuous covariate age.
You are not allowed to type `margins age`; doing that will produce an error:

```
margins age
factor 'age' not found in list of covariates
r(322);
```

The message “‘age’ not found in list of covariates” is `margins`’ way of saying, “Yes, age might be in the model, but if it is, it is not included as a factor variable; it is in as a continuous variable.” Sometimes, Stata is overly terse. `margins` might also say that because age is continuous there are an infinite number of values at which it could evaluate the margins. At what value(s) should age be fixed? `margins` requires more guidance with continuous covariates. We can provide that guidance by using the `at()` option and typing

```
margins, at(age=40)
```

To understand why that yields the desired result, let us tell you that if you were to type

```
margins
```

`margins` would report the overall margin—the margin that holds nothing constant. Because our model is logistic, the average value of the predicted probabilities would be reported. The `at()` option fixes one or more covariates to the value(s) specified and can be used with both factor and continuous variables. Thus, if you typed `margins, at(age=40)`, then `margins` would average over the data the responses for everybody, setting age=40. Here is what happens when you type that:

```
margins, at(age=40)
```

```
Predictive margins Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
at : age = 40

| Delta-method | Margin | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|--------------|--------|-----------|------|-----|---------------------|
| _cons        | .1133603 | .0070731 | 16.03 | 0.000 | .0994972 -.1272234 |
```

Reported is the margin for age = 40, adjusted for the other covariates in our model.

If we wanted to obtain the margins for age 30, 35, 40, 45, and 50, we could type

```
margins, at(age=(30 35 40 45 50))
```

or, equivalently,

```
margins, at(age=(30(5)50))
```

**Example 8: Margins of interactions**

Our model is

```
logistic outcome i.sex i.group sex#group age
```
We can obtain the margins of all possible combinations of the levels of `sex` and the levels of `group` by typing

```
.margins sex#group
```

Predictive margins

<table>
<thead>
<tr>
<th>Expression</th>
<th>Number of obs = 3,000</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model VCE</td>
<td>OIM</td>
</tr>
<tr>
<td>Expression</td>
<td>Pr(outcome), predict()</td>
</tr>
</tbody>
</table>

| sex#group  | Margin | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|------------|--------|-----------|------|------|---------------------|
| male#1     | .2379605 | .0237178  | 10.03 | 0.000 | .1914745 .2844465   |
| male#2     | .0658294 | .0105278  | 6.25  | 0.000 | .0451953 .0864636   |
| male#3     | .0538001 | .0136561  | 3.94  | 0.000 | .0270347 .0805656   |
| female#1   | .2158632 | .0112968  | 19.11 | 0.000 | .1937218 .2380045   |
| female#2   | .2054406 | .0183486  | 11.20 | 0.000 | .1694781 .2414032   |
| female#3   | .085448  | .0533914  | 1.60  | 0.110 | -.0191973 .1900932  |

The first line in the table reports the marginal probability for `sex` = 0 (male) and `group` = 1. That is, it reports the estimated probability if everyone in the data were treated as if they were `sex` = 0 and `group` = 1.

Also reported are all the other combinations of `sex` and `group`.

By the way, we could have typed `margins sex#group` even if our fitted model did not include `sex#group`. Estimation is one thing, and asking questions about the nature of the estimates is another. `margins` does, however, require that `i.sex` and `i.group` appear somewhere in the model, because fixing a value outside the model would just produce the grand margin, and you can separately ask for that if you want it by typing `margins` without arguments.

**Example 9: Decomposing margins**

We have the model

```
.logistic outcome i.sex i.group sex#group age
```

In example 6, we typed `margins sex` and obtained 0.160 for males and 0.197 for females. We are going to decompose each of those numbers. Let us explain:

1. The margin for males, 0.160, treats everyone as if they were male, and that amounts to simultaneously
   1a. treating males as males and
   1b. treating females as males.
2. The margin for females, 0.197, treats everyone as if they were female, and that amounts to simultaneously
   2a. treating males as females and
   2b. treating females as females.

The margins 1a and 1b are the decomposition of 1, and the margins 2a and 2b are the decomposition of 2.

We could obtain 1a and 2a by typing

```
.margins if sex==0, at(sex=(0 1))
```
because the qualifier \texttt{if sex==0} would restrict \texttt{margins} to running on only the males. Similarly, we could obtain 1b and 2b by typing

\begin{verbatim}
. margins if sex==1, at(sex=(0 1))
\end{verbatim}

We run these examples below:

\begin{verbatim}
. margins if sex==0, at(sex=(0 1))
Predictive margins Number of obs = 1,498
Model VCE : OIM
Expression : Pr(outcome), predict()
 1._at : sex = 0
 2._at : sex = 1

\begin{tabular}{lccccc}
 & Delta-method & & & & \\
 & Margin & Std. Err. & z & P>|z| & [95\% Conf. Interval] \\
\hline
  _at & & & & & \\
1 & .0794393 & .0062147 & 12.78 & 0.000 & .0672586 \ 0.0916199 \\
2 & .1335584 & .0127351 & 10.49 & 0.000 & .1085981 \ 0.1585187 \\
\hline
\end{tabular}
\end{verbatim}

\begin{verbatim}
. margins if sex==1, at(sex=(0 1))
Predictive margins Number of obs = 1,502
Model VCE : OIM
Expression : Pr(outcome), predict()
 1._at : sex = 0
 2._at : sex = 1

\begin{tabular}{lccccc}
 & Delta-method & & & & \\
 & Margin & Std. Err. & z & P>|z| & [95\% Conf. Interval] \\
\hline
  _at & & & & & \\
1 & .2404749 & .0199709 & 12.04 & 0.000 & .2013326 \ .2796171 \\
2 & .2596538 & .0104756 & 24.79 & 0.000 & .2391219 \ .2801857 \\
\hline
\end{tabular}
\end{verbatim}

Putting together the results from example 6 and the results above, we have

\begin{verbatim}
Margin treating everybody as themself \hspace{1cm} 0.170
Margin treating everybody as male \hspace{1cm} 0.160
Margin treating male as male \hspace{1cm} 0.079
Margin treating female as male \hspace{1cm} 0.240
Margin treating everybody as female \hspace{1cm} 0.197
Margin treating male as female \hspace{1cm} 0.134
Margin treating female as female \hspace{1cm} 0.260
\end{verbatim}

**Example 10: Testing margins—contrasts of margins**

Continuing with the previous example, it would be interesting to test the equality of 2b and 1b, to test whether the average probability of a positive outcome for females treated as females is equal to that for females treated as males. That test would be different from testing the overall significance of \texttt{sex} in our model. The test performed on our model would be a test of whether the probability of a positive outcome differs between males and females when they have equal values of the other covariates. The test of equality of margins is a test of whether the average probabilities differ given the different pattern of values of the other covariates that the two sexes have in our data.
We can also perform such tests by treating the results from `margins` as estimation results. There are three steps required to perform tests on margins. First, you must arrange it so that all the margins of interest are reported by just one `margins` command. Second, you must specify `margins`’ post option. Third, you perform the test with the `test` command.

Such tests and comparisons can be readily performed by contrasting margins; see `[R] margins, contrast`. Also see `Contrasts of margins—effects (discrete marginal effects)` in `[R] marginsplot`.

In the previous example, we used two commands to obtain our results, namely,

```
. margins if sex==0, at(sex=(0 1))
. margins if sex==1, at(sex=(0 1))
```

We could, however, have obtained the same results by typing just one command:

```
. margins, over(sex) at(sex=(0 1))
```

Performing `margins, over(sex)` first restricts the sample to `sex==0` and then restricts it to `sex==1`, and that is equivalent to the two different `if` conditions that we specified before.

To test whether females treated as females is equal to females treated as males, we will need to type

```
. margins, over(sex) at(sex=(0 1)) post
   . test _b[2._at#1.sex] = _b[1._at#1.sex]
```

We admit that the second command may seem to have come out of nowhere. When we specify `post` on the `margins` command, `margins` behaves as if it were an estimation command, which means that 1) it posts its estimates and full VCE to `e()`, 2) it gains the ability to replay results just as any estimation command can, and 3) it gains access to the standard postestimation commands. Item 3 explains why we could use `test`. We learned that we wanted to test `_b[2._at#1.sex]` and `_b[1._at#1.sex]` by replaying the estimation results, but this time with the standard estimation command `coeflegend` option. So what we typed was

```
. margins, over(sex) at(sex=(0 1)) post
   . margins, coeflegend
   . test _b[2._at#1.sex] = _b[1._at#1.sex]
```
We will let you try `margins, coeflegend` for yourself. The results of running the other two commands are

```
. margins, over(sex) at(sex=(0 1)) post
```

```
Predictive margins Number of obs  =  3,000
Model VCE : OIM
Expression : Pr(outcome), predict()  
over : sex

1._at : 0.sex
    sex  =  0
    1.sex
    sex  =  0

2._at : 0.sex
    sex  =  1
    1.sex
    sex  =  1

Delta-method
Margin Std. Err.  z  P>|z|  [95% Conf. Interval]
_at#sex  
1#male  .0794393  .0062147 12.78 0.000  .0672586  .0916199
1#female  .2404749  .0199709 12.04 0.000  .2013326  .2796171
2#male  .1335584  .0127351 10.49 0.000  .1085981  .1585187
2#female  .2596538  .0104756 24.79 0.000  .2391219  .2801857
```

```
. test _b[2._at#1.sex] = _b[1._at#1.sex]
( 1)  - 1bn._at#1.sex + 2._at#1.sex = 0
chi2(  1) = 0.72
Prob > chi2 = 0.3951
```

We can perform the same test in one command using contrasts of margins:

```
. logistic outcome i.sex i.group sex#group age
(output omitted)
. margins, over(sex) at(sex=(0 1)) contrast(atcontrast(r._at) wald)
```

```
Contrasts of predictive margins
Model VCE : OIM
Expression : Pr(outcome), predict()  
over : sex

1._at : 0.sex
    sex  =  0
    1.sex
    sex  =  0

2._at : 0.sex
    sex  =  1
    1.sex
    sex  =  1

We refitted our logistic model because its estimation results were replaced when we posted our margins. The syntax to perform the contrast we want is admittedly not obvious. Contrasting (testing) across \texttt{at()} groups is more difficult than contrasting across the margins themselves or across \texttt{over()} groups, because we have no natural place for the contrast operators (\texttt{r.}, in our case). We also explicitly requested Wald tests of the contrasts, which are not provided by default. Nevertheless, the chi-squared statistic and its \textit{p}-value for (2 vs 1) for \texttt{male} matches the results of our \texttt{test} command. We also obtain the test of whether the response of males treated as males is equal to the response of males treated as females.

For a gentler introduction to contrasts of margins, see \cite{Rmarginscontrast}.

### Example 11: Margins of a specified prediction

We will fit the model

```stata
use http://www.stata-press.com/data/r14/margex
tobit ycn i.sex i.group sex#group age, ul(90)
```

and we will tell the following story about the variables: We run a peach orchard where we allow people to pick their own peaches. A person receives one empty basket in exchange for $20, along with the right to enter the orchard. There is no official limit on how many peaches a person can pick, but only 90 peaches will fit into a basket. The dependent variable in the above tobit model, \texttt{ycn}, is the number of peaches picked. We use tobit, a special case of censored-normal regression, because \texttt{ycn} is censored at 90.

After fitting this model, if we typed

```stata
margins sex
```

we would obtain the margins for males and for females of the uncensored number of peaches picked. We would obtain that because \texttt{predict} after \texttt{tobit} produces the uncensored number by default. To obtain the censored prediction, we would have to specify \texttt{predict's ystar(.,90)} option. If we want the margins based on that response, we type

```stata
margins sex, predict(ystar(.,90))
```
The results of typing that are

```
tobit ycn i.sex i.group sex#group age, ul(90)
(output omitted)
```

. margins sex, predict(ystar(.90))

Predictive margins  Number of obs = 3,000
Model VCE : OIM
Expression : E(ycn*|ycn<90), predict(ystar(.90))

| sex    | Delta-method Margin | Std. Err. | z   | P>|z|   | [95% Conf. Interval] |
|--------|----------------------|-----------|-----|-------|----------------------|
| male   | 62.21804             | .5996928  | 103.75 | 0.000 | 61.04266 63.39342    |
| female | 78.34272             | .455526   | 171.98 | 0.000 | 77.4499 79.23553     |

In our previous examples, sex = 1 has designated females, so evidently the females visiting our orchard are better at filling baskets than the men.

**Example 12: Margins of a specified expression**

Continuing with our peach orchard example and the previously fit model

```
use http://www.stata-press.com/data/r14/margex
tobit ycn i.sex i.group sex#group age, ul(90)
```

let's examine how well our baskets are working for us. What is the proportion of the number of peaches actually picked to the number that would have been picked were the baskets larger? As mentioned in example 11, predict, ystar(.90) produces the expected number picked given the limit of basket size. predict, xb would predict the expected number without a limit. We want the ratio of those two predictions. That ratio will measure as a proportion how well the baskets work. Thus we could type

. margins sex, expression(predict(ystar(.90))/predict(xb))

That would give us the proportion for everyone treated as male and everyone treated as female, but what we want to know is how well baskets work for true males and true females, so we will type

. margins, over(sex) expression(predict(ystar(.90))/predict(xb))

```
margins, over(sex) expression(predict(ystar(0,90))/predict(xb))
```

| sex    | Delta-method Margin | Std. Err. | z   | P>|z|   | [95% Conf. Interval] |
|--------|----------------------|-----------|-----|-------|----------------------|
| male   | .9811785             | .0013037  | 752.60 | 0.000 | .9786233 .9837337     |
| female | .9419962             | .0026175  | 359.88 | 0.000 | .936866 .9471265      |

By the way, we could count the number of peaches saved by the limited basket size during the period of data collection by typing
The number of peaches saved turns out to be 9,183.

**Example 13: Margins with multiple outcomes (responses)**

Estimation commands such as *mlogit* and *mprobit* (see [R] *mlogit* and [R] *mprobit*) calculate multiple responses, and those multiple responses are reflected in the options available with *predict* after estimation. Obtaining margins for such estimators is thus the same as obtaining margins of a specified prediction, which was demonstrated in example 11. The solution is to include the *predict_opt* that selects the desired response in *margins*’ *predict(predict_opt)* option.

If we fit the multinomial logistic model

```
. mlogit group i.sex age
```

then to obtain the margins for the probability that group = 1, we would type

```
. margins sex, predict(outcome(1))
```

and to obtain the margins for the probability that group = 3, we would type

```
. margins sex, predict(outcome(3))
```

To obtain the margins for each of these outcomes simultaneously, type

```
. margins sex, predict(outcome(1)) predict(outcome(3))
```

We learned about the *outcome(1)* and *outcome(3)* options by looking in [R] *mlogit postestimation*. For an example using *margins* with a multiple-outcome estimator, see example 4 in [R] *mlogit postestimation*.

**Example 14: Margins with multiple equations**

Estimation commands such as *mvreg, manova, sureg*, and *reg3* (see [MV] *mvreg*, [MV] *manova*, [R] *sureg*, and [R] *reg3*) fit multiple equations. Obtaining margins for such estimators is the same as obtaining margins with multiple outcomes (see example 13), which in turn is the same as obtaining margins of a specified prediction (see example 11). You place the relevant option from the estimator’s *predict* command into *margins*’ *predict(predict_opt)* option.

If we fit the seemingly unrelated regression model

```
. sureg (y = i.sex age) (distance = i.sex i.group)
```

we can obtain the marginal means of *y* for males and females by typing

```
. margins sex, predict(equation(y))
```

and we can obtain the marginal means of *distance* by typing

```
. margins sex, predict(equation(distance))
```

We could obtain the difference between the margins of *y* and *distance* by typing

```
. margins sex, expression(predict(equation(y)) - > predict(equation(distance)))
```

More examples can be found in [MV] *manova* and [MV] *manova postestimation*. 
Example 15: Margins evaluated out of sample

You can fit your model on one dataset and use margins on another if you specify margins’ noesample option. Remember that margins reports estimated average responses, and, unless you lock all the covariates at fixed values by using the at() option, the remaining variables are allowed to vary as they are observed to vary in the data. That is indeed the point of using margins. The fitted model provides the basis for adjusting for the remaining variables, and the data provide their values. The predictions produced by margins are of interest assuming the data used by margins are in some sense interesting or representative. In some cases, you might need to fit your model on one set of data and perform margins on another.

In example 11, we fit the model

```
. tobit ycn i.sex i.group sex#group age, ul(90)
```

and we told a story about our peach orchard in which we charged people $20 to collect a basket of peaches, where baskets could hold at most 90 peaches. Let us now tell you that we believe the data on which we estimated those margins were unrepresentative, or at least, we have a more representative sample stored in another .dta file. That dataset includes the demographics of our customers but does not include counts of peaches picked. It is a lot of work counting those peaches.

Thus we will fit our model just as we did previously using the detailed data, but we will bring the other, more representative dataset into memory before issuing the margins sex, predict(ystar(.,90)) command, and we will add noesample to it.

```
. use http://www.stata-press.com/data/r14/margex
(Artificial data for margins)
. tobit ycn i.sex i.group sex#group age, ul(90)
(output omitted)
. use http://www.stata-press.com/data/r14/peach
. margins sex, predict(ystar(.,90)) noesample
Predictive margins Number of obs = 2,727
Model VCE : OIM
Expression : E(ycn*|ycn<90), predict(ystar(.,90))

| Delta-method | Margin | Std. Err. | z     | P>|z|  | [95% Conf. Interval] |
|--------------|--------|-----------|-------|------|----------------------|
| sex          |        |           |       |      |                      |

| 1            | 75.02146 | .643742   | 116.54 | 0.000| 73.75975  76.28317   |
```

In example 12, we produced an estimate of the number of peaches saved by the limited-size baskets. We can update that estimate using the new demographic data by typing

```
. count 2,727
. margins, exp(2727*(predict(xb)-predict(ystar(.,90)))) noesample
(output omitted)
```

By running the above, we find that the updated number of peaches saved is 6,408.
Obtaining margins of derivatives of responses (a.k.a. marginal effects)

Derivatives of responses are themselves responses, so everything said above in Obtaining margins of responses is equally true of derivatives of responses, and every example above could be repeated here substituting the derivative of the response for the response.

Derivatives are of interest because they are an informative way of summarizing fitted results. The change in a response for a change in the covariate is easy to understand and to explain. In simple models, one hardly needs margins to assist in obtaining such margins. Consider the simple linear regression

\[ y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \epsilon \]

The derivatives of the responses are

\[ \frac{dy}{d(\text{sex})} = \beta_1 \]
\[ \frac{dy}{d(\text{age})} = \beta_2 \]

The derivatives are the fitted coefficients. How does \( y \) change between males and females? It changes by \( \beta_1 \). How does \( y \) change with age? It changes by \( \beta_2 \) per year.

If you make the model a little more complicated, however, the need for margins arises. Consider the model

\[ y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \epsilon \]

Now the derivative with respect to age is

\[ \frac{dy}{d(\text{age})} = \beta_2 + 2 \times \beta_3 \times \text{age} \]

The change in \( y \) for a change in age itself changes with age, and so to better understand the fitted results, you might want to make a table of the change in \( y \) for a change in age for age = 30, age = 40, and age = 50. margins can do that.

Consider an even more complicated model, such as

\[ y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \beta_4 \times \text{bp} + \beta_5 \times \text{sex} \times \text{bp} + \beta_6 \times \text{tmt} + \beta_7 \times \text{tmt} \times \text{age} + \beta_8 \times \text{tmt} \times \text{age}^2 + \epsilon \]

The derivatives are

\[ \frac{dy}{d(\text{sex})} = \beta_1 + \beta_5 \times \text{bp} \]
\[ \frac{dy}{d(\text{age})} = \beta_2 + 2 \times \beta_3 \times \text{age} + \beta_7 \times \text{tmt} + 2 \times \beta_8 \times \text{tmt} \times \text{age} \]
\[ \frac{dy}{d(\text{bp})} = \beta_4 + \beta_5 \times \text{sex} \]
\[ \frac{dy}{d(\text{tmt})} = \beta_6 + \beta_7 \times \text{age} + \beta_8 \times \text{age}^2 \]

At this point, margins becomes indispensable.
Use at() freely, especially with continuous variables

An option one tends to use frequently with derivatives of responses is at(). Such use is often to better understand or to communicate how the response varies, or, in technical jargon, to explore the nature of the response surface.

For instance, the effect $dy/d(tmt)$ in (1) is equal to $\beta_6 + \beta_7 \times \text{age} + \beta_8 \times \text{age}^2$, and so simply to understand how treatment varies with age, we may want to fix age at various values. We might type

```
.margins, dydx(tmt) at(age=(30 40 50))
```

Expressing derivatives as elasticities

You specify the dydx(varname) option on the margins command to use $dy/d(varname)$ as the response variable. If you want that derivative expressed as an elasticity, you can specify eyex(varname), eydx(varname), or dyex(varname). You substitute e for d where you want an elasticity. The formulas are

$$
\begin{align*}
dydx() &= dy/dx \\
eyex() &= dy/dx \times (x/y) \\
eydx() &= dy/dx \times (1/y) \\
dyex() &= dy/dx \times (x)
\end{align*}
$$

and the interpretations are

- $dydx()$: change in $y$ for a change in $x$
- $eyex()$: proportional change in $y$ for a proportional change in $x$
- $eydx()$: proportional change in $y$ for a change in $x$
- $dyex()$: change in $y$ for a proportional change in $x$

As margins always does with response functions, calculations are made at the observational level and are then averaged. Let’s assume that in observation 5, $dy/dx = 0.5$, $y = 15$, and $x = 30$; then

$$
\begin{align*}
dydx() &= 0.5 \\
eyex() &= 1.0 \\
eydx() &= 0.03 \\
dyex() &= 15.0
\end{align*}
$$

Many social scientists would informally explain the meaning of $eyex() = 1$ as “$y$ increases 100% when $x$ increases 100%” or as “$y$ doubles when $x$ doubles”, although neither statement is literally true. $eyex()$, $eydx()$, and $dyex()$ are rates evaluated at a point, just as $dydx()$ is a rate, and all such interpretations are valid only for small (infinitesimal) changes in $x$. It is true that $eyex() = 1$ means $y$ increases with $x$ at a rate such that, if the rate were constant, $y$ would double if $x$ doubled. This issue of casual interpretation is no different from casually interpreting $dydx()$ as if it represents the response to a unit change. It is not necessarily true that $dydx() = 0.5$ means that “$y$ increases by 0.5 if $x$ increases by 1”. It is true that “$y$ increases with $x$ at a rate such that, if the rate were constant, $y$ would increase by 0.5 if $x$ increased by 1”.

$dydx()$, $eyex()$, $eydx()$, and $dyex()$ may be used with continuous $x$ variables. $dydx()$ and $eydx()$ may also be used with factor variables.
**Derivatives versus discrete differences**

In (1),

\[ y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \beta_4 \times \text{bp} + \beta_5 \times \text{sex} \times \text{bp} + \beta_6 \times \text{tmt} + \beta_7 \times \text{tmt} \times \text{age} + \beta_8 \times \text{tmt} \times \text{age}^2 + \epsilon \]

Let us call your attention to the derivatives of \( y \) with respect to age and sex:

\[ \frac{dy}{d(\text{age})} = \beta_2 + 2 \times \beta_3 \times \text{age} + \beta_7 \times \text{tmt} + 2 \times \beta_8 \times \text{tmt} \times \text{age} \]  

(2)

\[ \frac{dy}{d(\text{sex})} = \beta_1 + \beta_5 \times \text{bp} \]  

(3)

\text{age} is presumably a continuous variable and (2) is precisely how \textit{margins} calculates its derivatives when you type \texttt{margins, dydx(age)}. \text{sex}, however, is presumably a factor variable, and \textit{margins} does not necessarily make the calculation using (3) were you to type \texttt{margins, dydx(sex)}. We will explain, but let us first clarify what we mean by a continuous and a factor variable. Say that you fit (1) by typing

\[
\texttt{. regress y i.sex age c.age#c.age i.bp bp#sex} \\
> \texttt{i.tmt tmt#c.age tmt#c.age#c.age}
\]

It is important that \texttt{sex} entered the model as a factor variable. It would not do to type \texttt{regress y sex...} because then \texttt{sex} would be a continuous variable, or at least it would be a continuous variable from Stata’s point of view. The model estimates would be the same, but \textit{margins}’ understanding of those estimates would be a little different. With the model estimated using \texttt{i.sex}, \textit{margins} understands that either \texttt{sex} is 0 or \texttt{sex} is 1. With the model estimated using \texttt{sex}, \textit{margins} thinks \texttt{sex} is continuous and, for instance, \texttt{sex = 1.5} is a possibility.

\textit{margins} calculates \texttt{dydx()} differently for continuous and for factor variables. For continuous variables, \textit{margins} calculates \texttt{dy/dx}. For factor variables, \textit{margins} calculates the discrete first-difference from the base category. To obtain that for \texttt{sex}, write down the model and then subtract from it the model evaluated at the base category for \texttt{sex}, which is \texttt{sex = 0}. If you do that, you will get the same formula as we obtained for the derivative, namely,

\[
\text{discrete difference}\{(\texttt{sex = 1}) - (\texttt{sex = 0})\} = \beta_1 + \beta_5 \times \text{bp}
\]

We obtain the same formula because our model is linear regression. Outside of linear regression, and outside of linear response functions generally, the discrete difference is not equal to the derivative. The discrete difference is not equal to the derivative for logistic regression, probit, etc. The discrete difference calculation is generally viewed as better for factor variables than the derivative calculation because the discrete difference is what would actually be observed.

If you want the derivative calculation for your factor variables, specify the \texttt{continuous} option on the \textit{margins} command.

**Example 16: Average marginal effect (partial effects)**

Concerning the title of this example, the way we use the term marginal effect, the effects of factor variables are calculated using discrete first-differences. If you wanted the continuous calculation, you would specify \textit{margins}’ \texttt{continuous} option in what follows.
. use http://www.stata-press.com/data/r14/margex
(Artificial data for margins)
. logistic outcome treatment##group age c.age#c.age treatment#c.age
(output omitted)
. margins, dydx(treatment)

Average marginal effects Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
dy/dx w.r.t. : 1.treatment

| Delta-method | dy/dx | Std. Err. | z | P>|z| | [95% Conf. Interval] |
|--------------|-------|-----------|---|------|----------------------|
| 1.treatment  | 0.0385625 | 0.0162848 | 2.37 | 0.018 | 0.0066449 | 0.0704801 |

Note: dy/dx for factor levels is the discrete change from the base level.

The average marginal effect of treatment on the probability of a positive outcome is 0.039.

Example 17: Average marginal effect of all covariates

We will continue with the model

. logistic outcome treatment##group age c.age#c.age treatment#c.age

if we wanted the average marginal effects for all covariates, we would type margins, dydx(*) or margins, dydx(_all); they mean the same thing. This is probably the most common way margins, dydx() is used.

. margins, dydx(*)

Average marginal effects Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
dy/dx w.r.t. : 1.treatment 2.group 3.group age

| Delta-method | dy/dx | Std. Err. | z | P>|z| | [95% Conf. Interval] |
|--------------|-------|-----------|---|------|----------------------|
| 1.treatment  | 0.0385625 | 0.0162848 | 2.37 | 0.018 | 0.0066449 | 0.0704801 |
| group        |       |           |    |      |                      |
| 2            | -.0776906 | 0.0181584 | -4.28 | 0.000 | -.1132805 | -.0421007 |
| 3            | -.1505652 | 0.0400882 | -3.76 | 0.000 | -.2291366 | -.0719937 |
| age          | .0095868  | 0.0007796 | 12.30 | 0.000 | .0080589 | .0111148 |

Note: dy/dx for factor levels is the discrete change from the base level.

Example 18: Evaluating marginal effects over the response surface

Continuing with the model

. logistic outcome treatment##group age c.age#c.age treatment#c.age

What follows maps out the entire response surface of our fitted model. We report the marginal effect of treatment evaluated at age = 20, 30, ..., 60, by each level of group.
. margins group, dydx(treatment) at(age=(20(10)60))

Conditional marginal effects
Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
dy/dx w.r.t. : 1.treatment

Obtaining margins with survey data and representative samples

The standard errors and confidence intervals produced by margins are based by default on the delta method applied to the VCE of the current estimates. Delta-method standard errors treat the covariates at which the response is evaluated as given or fixed. Such standard errors are appropriate if you specify at() to fix the covariates, and they are appropriate when you are making inferences about groups exactly like your sample whether you specify at() or not.

On the other hand, if you have a representative sample of the population or if you have complex survey data and if you want to make inferences about the underlying population, you need to account for the variation in the covariates that would arise in repeated sampling. You do that using vce(unconditional), which invokes a different standard-error calculation based on Korn and Graubard (1999). Syntactically, there are three cases. They all involve specifying the vce(unconditional) option on the margins command:

1. You have a representative random sample, and you have not svyset your data.
   When you fit the model, you need to specify the vce(robust) or vce(cluster clustvar) option. When you issue the margins command, you need to specify the vce(unconditional) option.
2. You have a weighted sample, and you have not `svyset` your data.
   You need to specify `[pw=weight]` when you fit the model and, of course, specify the `vce(unconditional)` option on the `margins` command. You do not need to specify the weights on the `margins` command because `margins` will obtain them from the estimation results.

3. You have `svyset` your data, whether it be a simple random sample or something more complex including weights, strata, sampling units, or poststratification, and you are using the linearized variance estimator.
   You need to use the `svy` prefix when you fit the model. You need to specify `vce(unconditional)` when you issue the `margins` command. You do not need to respecify the weights.

   Even though the data are `svyset`, and even though the estimation was `svy` estimation, `margins` does not default to `vce(unconditional)`. It does not default to `vce(unconditional)` because there are valid reasons to want the data-specific, `vce(delta)` standard-error estimates. Whether you specify `vce(unconditional)` or not, `margins` uses the weights, so you do not need to respecify them even if you are using `vce(unconditional)`. `vce(unconditional)` is allowed only after estimation with `vce(robust)`, `vce(cluster ...)` or the `svy` prefix with the linearized variance estimator. If the VCE of the current estimates was specified as clustered, so will be the VCE estimates of `margins`. If the estimates were from a survey estimation, the survey settings in the dataset will be used by `margins`.

   When you use `vce(unconditional)`, never specify `if exp` or `in range` on the `margins` command; instead, specify the `subpop(if exp)` option. You do that for the usual reasons; see `[SVY] subpopulation estimation`. If you specify `over(varlist)` to examine subgroups, the subgroups will automatically be treated as subpopulations.

   If you are using a replication-based variance estimator, you may want to use this method to estimate the variance of your margins; see `[SVY] svy postestimation`.

Example 19: Inferences for populations, margins of response

In example 6, we fit the model

```
    . logistic outcome i.sex i.group sex#group age
```

and we obtained margins by sex and margins by group,

```
    . margins sex group
```

If our data were randomly drawn from the population of interest and we wanted to account for this, we would have typed

```
    . logistic outcome i.sex i.group sex#group age, vce(robust)
    . margins sex group, vce(unconditional)
```

We do that below:
. logistic outcome i.sex i.group sex#group age, vce(robust)
(output omitted)
. margins sex group, vce(unconditional)

Predictive margins

Expression : Pr(outcome), predict()
Number of obs = 3,000

|               | Unconditional | Std. Err. | z  | P>|z|  | 95% Conf. Interval |
|---------------|---------------|-----------|----|------|-------------------|
| sex           |               |           |    |      |                   |
| male          | .1600644      | .0131685  | 12.16 | 0.000 | .1342546 - .1858743 |
| female        | .1966902      | .0104563  | 18.81 | 0.000 | .1761963 - .2171841 |
| group         |               |           |    |      |                   |
| 1             | .2251302      | .0127069  | 17.72 | 0.000 | .200225 - .2500354 |
| 2             | .150603       | .0118399  | 12.72 | 0.000 | .1273972 - .1738088 |
| 3             | .0736157      | .0343188  | 2.15  | 0.032 | .0063522 - .1408793 |

The estimated margins are the same as they were in example 6, but the standard errors and confidence intervals differ, although not by much. Given that we have 3,000 observations in our randomly drawn sample, we should expect this.

Example 20: Inferences for populations, marginal effects

In example 17, we fit a logistic model and then obtained the average marginal effects for all covariates by typing

. logistic outcome treatment##group age c.age#c.age treatment#c.age
e. margins, dydx(*)

To repeat that and also obtain standard errors for our population, we would type

. logistic outcome treatment##group age c.age#c.age treatment#c.age,
> vce(robust)
.e. margins, dydx(*) vce(unconditional)

The results are

. logistic outcome treatment##group age c.age#c.age treatment#c.age, vce(robust)
(output omitted)
.e. margins, dydx(*) vce(unconditional)

Average marginal effects

Expression : Pr(outcome), predict()
dy/dx w.r.t. : 1.treatment 2.group 3.age

|               | Unconditional | Std. Err. | z  | P>|z|  | 95% Conf. Interval |
|---------------|---------------|-----------|----|------|-------------------|
| 1.treatment   | .0385625      | .0163872  | 2.35 | 0.019 | .0064442 - .0706808 |
| group         |               |           |    |      |                   |
| 2             | -.0776906     | .0179573  | -4.33 | 0.000 | -.1128863 - -.0424949 |
| 3             | -.1505652     | .0411842  | -3.66 | 0.000 | -.2312848 - -.0698456 |
| age           | .0095868      | .0007814  | 12.27 | 0.000 | .0080553 - .0111183 |

Note: dy/dx for factor levels is the discrete change from the base level.
Example 21: Inferences for populations with svyset data

See example 3 in [SVY] svy postestimation.

Standardizing margins

A standardized margin is the margin calculated on data different from the data used to fit the model. Typically, the word standardized is reserved for situations in which the alternate population is a reference population, which may be real or artificial, and which is treated as fixed.

Say that you work for a hospital and have fit a model of mortality on the demographic characteristics of the hospital’s patients. At this stage, were you to type

```
  . margins
```

you would obtain the mortality rate for your hospital. You have another dataset, hstandard.dta, that contains demographic characteristics of patients across all hospitals along with the population of each hospital recorded in the pop variable. You could obtain the expected mortality rate at your hospital if your patients matched the characteristics of the standard population by typing

```
  . use http://www.stata-press.com/data/r14/hstandard, clear
  . margins [fw=pop], noesample
```

You specified `noesample` because the margin is being calculated on data other than the data used to estimate the model. You specified `[fw=pop]` because the reference dataset you are using included population counts, as many reference datasets do.

Obtaining margins as though the data were balanced

Here we discuss what are commonly called estimated marginal means or least-squares means. These are margins assuming that all levels of factor variables are equally likely or, equivalently, that the design is balanced. The seminal reference on these margins is Searle, Speed, and Milliken (1980).

In designed experiments, observations are often allocated in a balanced way so that the variances can be easily compared and decomposed. At the Acme Portable Widget Company, they are experimenting with a new machine. The machine has three temperature settings and two pressure settings; a combination of settings will be optimal on any particular day, determined by the weather. At start-up, one runs a quick test and chooses the optimal setting for the day. Across different days, each setting will be used about equally, says the manufacturer.

In experiments with the machine, 10 widgets were collected for stress testing at each of the settings over a six-week period. We wish to know the average stress-test value that can be expected from these machines over a long period.

Balancing using `asbalanced`

The data were intended to be balanced, but unfortunately, the stress test sometimes destroys samples before the stress can be measured. Thus even though the experiment was designed to be balanced, the data are not balanced. You specify the `asbalanced` option to estimate the margins as if the data were balanced. We will type

```
  . use http://www.stata-press.com/data/r14/acmemanuf
  . regress y pressure##temp
  . margins, asbalanced
```
So that you can compare the `asbalanced` results with the observed results, we will also include `margins` without the `asbalanced` option in what follows:

```stata
use http://www.stata-press.com/data/r14/acmemanuf
regress y pressure##temp
(output omitted)
margins
Predictive margins Number of obs = 49
Model VCE : OLS
Expression : Linear prediction, predict()

<table>

<td>75.40</td>
<td>0.000</td>
<td>112.2899 118.4618</td>
</tr>
</tbody>
</table>
```

Technical note

Concerning how `asbalanced` calculations are performed, if a factor variable has `l` levels, then each level’s coefficient contributes to the response weighted by `1/l`. If two factors, `a` and `b`, interact, then each coefficient associated with their interaction is weighted by `1/(l_a \times l_b)`.

If a balanced factor interacts with a continuous variable, then each coefficient in the interaction is applied to the value of the continuous variable, and the results are weighted equally. So, if the factor being interacted has `l_a` levels, the effect of each coefficient on the value of the continuous covariate is weighted by `1/l_a`.

Balancing by standardization

To better understand the balanced results, we can perform the balancing ourselves by using the standardizing method shown in `Standardizing margins`. To do that, we will input a balanced dataset and then type `margins, noesample`.
. use http://www.stata-press.com/data/r14/acmemanuf
. regress y pressure##temp
(output omitted)
. drop _all
. input pressure temp
     pressure   temp
       1. 1   1
       2. 1   2
       3. 1   3
       4. 2   1
       5. 2   2
       6. 2   3
       7. end
. margins, noesample

Predictive margins  Number of obs =   6  
Model VCE : OLS  
Expression : Linear prediction, predict()

| Delta-method  | Margin | Std. Err. | t     | P>|t|  | [95% Conf. Interval] |
|---------------|--------|-----------|-------|-------|---------------------|
| _cons         | 115.3758 | 1.530199  | 75.40 | 0.000 | 112.2899            |

We obtain the same results as previously.

**Balancing nonlinear responses**

If our testing had produced a binary outcome, say, acceptable/unacceptable, rather than a continuous variable, we would type

. use http://www.stata-press.com/data/r14/acmemanuf, clear
. logistic acceptable pressure##temp
. margins, asbalanced

The result of doing that would be 0.680. If we omitted the asbalanced option, the result would have been 0.667. The two results are so similar because acmemanuf.dta is nearly balanced.

Even though the asbalanced option can be used on both linear and nonlinear responses, such as probabilities, there is an issue of which you should be aware. The most widely used formulas for balancing responses apply the balancing to the linear prediction, average that as if it were balanced, and then apply the nonlinear transform. That is the calculation that produced 0.680.

An alternative would be to apply the standardization method. That amounts to making the linear predictions observation by observation, applying the nonlinear transform to each, and then averaging the nonlinear result as if it were balanced. You could do that by typing

. use http://www.stata-press.com/data/r14/acmemanuf, clear
. logistic acceptable pressure##temp
. clear
. input pressure temp
(see above for entered data)
. margins, noesample
The result from the standardization procedure would be 0.672. These two ways of averaging nonlinear responses are discussed in detail in Lane and Nelder (1982) within the context of general linear models.

Concerning the method used by the `asbalanced` option, if your data start balanced and you have a nonlinear response, you will get different results with and without the `asbalanced` option!

### Treating a subset of covariates as balanced

So far, we have treated all the covariates as if they were balanced. `margins` will allow you to treat a subset of the covariates as balanced, too. For instance, you might be performing an experiment in which you are randomly allocating patients to a treatment arm and so want to balance on arm, but you do not want to balance the other characteristics because you want mean effects for the experiment’s population.

In this example, we will imagine that the outcome of the experiment is continuous. We type

```
. use http://www.stata-press.com/data/r14/margex, clear
. regress y arm##sex sex##agegroup
. margins, at((asbalanced) arm)
```

If we wanted results balanced on `agegroup` as well, we could type

```
. margins, at((asbalanced) arm agegroup)
```

If we wanted results balanced on all three covariates, we could type

```
. margins, at((asbalanced) arm agegroup sex)
```

or we could type

```
. margins, at((asbalanced) _factor)
```

or we could type

```
. margins, asbalanced
```

### Using `fvset` design

As a convenience feature, equivalent to

```
. regress y arm##sex sex##agegroup
. margins, at((asbalanced) arm sex)
```

is

```
. fvset design asbalanced arm sex
. regress y arm##sex sex##agegroup
. margins
```

The advantage of the latter is that you have to set the variables as balanced only once. This is useful when balancing is a design characteristic of certain variables and you wish to avoid accidentally treating them as unbalanced.

If you save your data after `fvset`ting, the settings will be remembered in future sessions. If you want to clear the setting(s), type

```
. fvset clear varlist
```

See [R] `fvset`. 

Balancing in the presence of empty cells

The issue of empty cells is not exclusively an issue of balancing, but there are special considerations when balancing. Empty cells are discussed generally in \textit{Estimability of margins}.

An empty cell is an interaction of levels of two or more factor variables for which you have no data. Usually, margins involving empty cells cannot be estimated. When balancing, there is an alternate definition of the margin that allows the margin to be estimated. \texttt{margins} makes the alternate calculation when you specify the \texttt{emptycells(reweight)} option. By default, \texttt{margins} uses the \texttt{emptycells(strict)} option.

If you have empty cells in your data and you request margins involving the empty cells, those margins will be marked as not estimable even if you specify the \texttt{asbalanced} option.

```
use http://www.stata-press.com/data/r14/estimability, clear
(margins estimability)
.regress y sex##group
(output omitted)
.margins sex, asbalanced
```

<table>
<thead>
<tr>
<th></th>
<th>Delta-method</th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Margin</td>
<td>Std. Err.</td>
<td>t</td>
<td>P&gt;</td>
<td>t</td>
</tr>
<tr>
<td>sex</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>male</td>
<td>21.91389</td>
<td>1.119295</td>
<td>19.58</td>
<td>0.000</td>
<td>19.67572  24.15206</td>
</tr>
<tr>
<td>female</td>
<td>.</td>
<td>(not estimable)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This example is discussed in \textit{Estimability of margins}, although without the \texttt{asbalanced} option. What is said there is equally relevant to the \texttt{asbalanced} case. For reasons explained there, the margin for \texttt{sex} = 1 (female) cannot be estimated.

The margin for \texttt{sex} = 1 can be estimated in the \texttt{asbalanced} case if you are willing to make an assumption. Remember that \texttt{margins} makes the balanced calculation by summing the responses associated with the levels and then dividing by the number of levels. If you specify \texttt{emptycells(reweight)}, \texttt{margins} sums what is available and divides by the number available. Thus you are assuming that, whatever the responses in the empty cells, those responses are such that they would not change the overall mean of what is observed.
The results of specifying `emptycells(reweight)` are

```
. margins sex, asbalanced emptycells(reweight)
```

| Sex   | Margin Std. Err. t P>|t| [95% Conf. Interval] |
|-------|---------------------|-------------------|
| male  | 21.91389 1.119295 19.58 0.000 19.67572 24.15206 |
| female| 24.85185 1.232304 20.17 0.000 22.38771 27.316 |

**Obtaining margins with nested designs**

**Introduction to nested designs**

Factors whose meaning depends on other factors are called nested factors, and the factors on which their meaning depends are called the nesting factors. For instance, assume that we have a sample of patients and each patient is assigned to one doctor. Then patient is nested within doctor. Let the identifiers of the first 5 observations of our data be

<table>
<thead>
<tr>
<th>Doctor</th>
<th>Patient</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>Fred</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Mary</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>Bob</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>Karen</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Hank</td>
</tr>
</tbody>
</table>

The first patient on one doctor’s list has nothing whatsoever to do with the first patient on another doctor’s list. The meaning of `patient = 1` is defined only when the value of `doctor` is supplied.

Nested factors enter into models as interactions of nesting and nested; the nested factor does not appear by itself. We might estimate a model such as

```
. regress y ... i.doctor doctor#patient ...
```

You do not include `i.patient` because the coding for patient has no meaning except within doctor. Patient 1 is Fred for doctor 1 and Karen for doctor 2, etc.

`margins` provides an option to help account for the structure of nested models. The `within(varlist)` option specifies that `margins` estimate and report a set of margins for the value combinations of `varlist`. We might type

```
. margins, within(doctor)
```

Margin calculations are performed first for `doctor = 1`, then for `doctor = 2`, and so on.

Sometimes you need to specify `within()`, and other times you do not. Let’s consider the particular model

```
. regress y i.doctor doctor#patient i.sex sex#doctor#patient
```
The guidelines are the following:

1. You may compute overall margins by typing `margins`.
2. You may compute overall margins within levels of a nesting factor by typing `margins, within(doctor)`.
3. You may compute margins of a nested factor within levels of its nesting factor by typing `margins patient, within(doctor)`.
4. You may compute margins of factors in your model, as long as the factor does not nest other factors and is not nested within other factors, by typing `margins sex`.
5. You may not compute margins of a nesting factor, such as `margins doctor`, because they are not estimable.

For examples using `within()`, see [R] `anova`.

**Margins with nested designs as though the data were balanced**

To obtain margins with nested designs as though the data were balanced, the guidelines are the same as above except that 1) you add the `asbalanced` option and 2) whenever you do not specify `within()`, you specify `emptycells(reweight)`. The updated guidelines are

1. You may compute overall margins by typing `margins, asbalanced emptycells(reweight)`.
2. You may compute overall margins within levels of a nesting factor by typing `margins, asbalanced within(doctor)`.
3. You may compute margins of a nested factor within levels of its nesting factor by typing `margins patient, asbalanced within(doctor)`.
4. You may compute margins of factors in your model, as long as the factor does not nest other factors and is not nested within other factors, by typing `margins sex, asbalanced emptycells(reweight)`.
5. You may not compute margins of a nesting factor, such as `margins doctor`, because they are not estimable.

Just as explained in *Using fvset design*, rather than specifying the `asbalanced` option, you may set the balancing characteristic on the factor variables once and for all by using the command `fvset design asbalanced varlist`.

**Technical note**

Specifying either `emptycells(reweight)` or `within(varlist)` causes `margins` to rebalance over all empty cells in your model. If you have interactions in your model that are not involved in the nesting, `margins` will lose its ability to detect estimability.

**Technical note**

Careful readers will note that the description of `within(varlist)` matches closely the description of `over(varlist)`. The concept of nesting is similar to the concept of subpopulations. `within()` differs from `over()` in that it gracefully handles the missing cells when margins are computed as balanced.
Coding of nested designs

In the *Introduction* to this section, we showed a coding of the nested variable `patient`, where the coding started over with each `doctor`:

<table>
<thead>
<tr>
<th>Doctor</th>
<th>Patient</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>Fred</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Mary</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>Bob</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>Karen</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Hank</td>
</tr>
</tbody>
</table>

That coding style is not required. The data could just as well have been coded

<table>
<thead>
<tr>
<th>Doctor</th>
<th>Patient</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>Fred</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Mary</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>Bob</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Karen</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
<td>Hank</td>
</tr>
</tbody>
</table>

or even

<table>
<thead>
<tr>
<th>Doctor</th>
<th>Patient</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1037239</td>
<td>Fred</td>
</tr>
<tr>
<td>1</td>
<td>2223942</td>
<td>Mary</td>
</tr>
<tr>
<td>1</td>
<td>0611393</td>
<td>Bob</td>
</tr>
<tr>
<td>2</td>
<td>4433329</td>
<td>Karen</td>
</tr>
<tr>
<td>2</td>
<td>6110271</td>
<td>Hank</td>
</tr>
</tbody>
</table>

Actually, either of the above two alternatives are better than the first one because *margins* will be better able to give you feedback about estimability should you make a mistake following the guidelines. On the other hand, both of these two alternatives require more memory at the estimation step. If you run short of memory, you will need to recode your patient ID to the first coding style, which you could do by typing

```
   . sort doctor patient
   . by doctor: generate newpatient = _n
```

Alternatively, you can set `emptycells drop` and continue to use your patient ID variable just as it is coded. If you do this, we recommend that you remember to type `set emptycells keep` when you are finished; *margins* is better able to determine estimability that way. If you regularly work with large nested models, you can set `emptycells keep` permanently so that the setting persists across sessions. See [R] *set emptycells*. 
Special topics

Requirements for model specification

The results that margins reports are based on the most recently fit model or, in Stata jargon, the most recently issued estimation command. Here we discuss 1) mechanical requirements for how you specify that estimation command, 2) work-arounds to use when those restrictions prove impossible, and 3) requirements for margins’ predict(pred_opt) option to work.

Concerning 1, when you specify the estimation command, covariates that are logically factor variables must be Stata factor variables, and that includes indicator variables, binary variables, and dummies. It will not do to type `. regress y ... female ...

even if female is a 0/1 variable. You must type

`. regress y ... i.female ...

If you violate this rule, you will not get incorrect results, but you will discover that you will be unable to obtain margins on female:

`. margins female
factor female not found in list of covariates
r(111);

It is also important that if the same continuous variable appears in your model more than once, differently transformed, those transforms be performed via Stata’s factor-variable notation. It will not do to type

`. generate age2 = age^2
`. regress y ... age age2 ...

You must type

`. regress y ... age c.age#c.age ...

You must do that because margins needs to know everywhere that variable appears in the model if it is to be able to set covariates to fixed values.

Concerning 2, sometimes the transformations you desire may not be achievable using the factor-variable notation; in those situations, there is a work-around. Let’s assume you wish to estimate

`. generate age1_5 = age^1.5
`. regress y ... age age1_5 ...

There is no factor-variable notation for including age and age^{1.5} in a model, so obviously you are going to obtain the estimates by typing just what we have shown. In what follows, it would be okay if there are interactions of age and age^{1.5} with other variables specified by the factor-variable notation, so the model could just as well be

`. regress y ... age age1_5 sex#c.age sex#c.age1_5 ...

Let’s assume you have fit one of these two models. On any subsequent margins command where you leave age free to vary, there will be no issue. You can type

`. margins female
and results will be correct. Issues arise when you attempt to fix age at predetermined values. The following would produce incorrect results:

```
. margins female, at(age=20)
```

The results would be incorrect because they leave `age1_5` free to vary, and, logically, fixing `age` implies that `age1_5` should also be fixed. Because we were unable to state the relationship between `age` and `age1_5` using the factor-variable notation, `margins` does not know to fix `age1_5` at 20. To get the correct results, you must fix the value of `age1_5` yourself:

```
. margins female, at(age=20 age1_5=89.442719)
```

That command produces correct results. In the command, 89.442719 is 20.5.

In summary, when there is a functional relationship between covariates of your model and that functional relationship is not communicated to `margins` via the factor-variable notation, then it becomes your responsibility to ensure that all variables that are functionally related are set to the appropriate fixed values when any one of them is set to a fixed value.

Concerning 3, we wish to amend our claim that you can calculate margins for anything that `predict` will produce. We need to add a qualifier. Let us show you an example where the statement is not true. After `regress`, `predict` will predict something it calls `pr(a,b)`, which is the probability $a \leq y \leq b$. Yet if we attempted to use `pr()` with `margins` after estimation by `regress`, we would obtain

```
. margins sex, predict(pr(10,20))
```

```
prediction is a function of possibly stochastic quantities other than e(b)
r(498);
```

What we should have stated was that you can calculate margins for anything that `predict` will produce for which all the estimated quantities used in its calculation appear in `e(V)`, the estimated VCE. `pr()` is a function of $\beta$, the estimated coefficients, and of $s^2$, the estimated variance of the residual. `regress` does not post the variance of the residual variance (sic) in `e(V)`, or even estimate it, and therefore, `predict(pr(10,20))` cannot be specified with `margins` after estimation by `regress`.

It is unlikely that you will ever encounter these kinds of problems because there are so few predictions where the components are not posted to `e(V)`. If you do encounter the problem, the solution may be to specify `nose` to suppress the standard-error calculation. If the problem is not with computing the margin, but with computing its standard error, `margins` will report the result:

```
. margins sex, predict(pr(10,20)) nose
(output appears with SEs, tests, and CIs left blank)
```

### Technical note

Programmers: If you run into this after running an estimation command that you have written, be aware that as of Stata 11, you are supposed to set in `e(marginsok)` the list of options allowed with `predict` that are okay to use with `margins`. When that list is not set, `margins` looks for violations of its assumptions and, if it finds any, refuses to proceed.
Estimability of margins

Sometimes margins will report that a margin cannot be estimated:

```
use http://www.stata-press.com/data/r14/estimability, clear
(margins estimability)
regress y sex##group
(output omitted)
margins sex
```

Predictive margins
Number of obs = 69
Model VCE : OLS
Expression : Linear prediction, predict()

| Delta-method          | Margin | Std. Err. | t    | P>|t|  | [95% Conf. Interval] |
|----------------------|--------|-----------|------|------|----------------------|
| sex                  | male   | 21        | 0.85 | 24.71| 0.000                |
|                      | female | (not estimable) |

In the above output, the margin for sex = 0 (male) is estimated, but the margin for sex = 1 (female) is not estimable. This occurs because of empty cells. An empty cell is an interaction of levels of two or more factor variables for which you have no data. In the example, the lack of estimability arises because we have two empty cells:

```
table sex group
```

<table>
<thead>
<tr>
<th>sex</th>
<th>group</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1 2</td>
</tr>
<tr>
<td>male</td>
<td>2 9 27</td>
</tr>
<tr>
<td>female</td>
<td>9 9 3</td>
</tr>
</tbody>
</table>

To calculate the marginal mean response for sex = 1, we have no responses to average over for group = 4 and group = 5. We obviously could calculate that mean for the observations that really are sex = 1, but remember, the marginal calculation for sex = 1 treats everyone as if female, and we will thus have 8 and 2 observations for which we have no basis for estimating the response.

There is no solution for this problem unless you are willing to treat the data as if it were balanced and adjust your definition of a margin; see *Balancing in the presence of empty cells*.

Manipulability of tests

Manipulability is a problem that arises with some tests, and in particular, arises with Wald tests. Tests of margins are based on Wald tests, hence our interest. This is a generic issue and not specific to the margins command.

Let’s understand the problem. Consider performing a test of whether some statistic \( \phi \) is 0. Whatever the outcome of that test, it would be desirable if the outcome were the same were we to test whether the \( \sqrt{\phi} \) were 0, or whether \( \phi^2 \) were 0, or whether any other monotonic transform of \( \phi \) were 0 (for \( \phi^2 \), we were considering only the positive half of the number line). If a test does not have that property, it is manipulable.

Wald tests are manipulable, and that means the tests produced by margins are manipulable. You can see this for yourself by typing
To compare the results from the two `margins` commands, we added the `df(.)` option to the first one, forcing it to report a \( z \) statistic even though a \( t \) statistic would have been appropriate in this case. We would prefer if the test against zero produced by `margins`, `df(.)` was equal to the test produced by `margins`, `expression(predict(xb)^2)`. But alas, they produce different results. The first produces \( z = 12.93 \), and the second produces \( z = 12.57 \).

The difference is not much in our example, but behind the scenes, we worked to make it small. We subtracted 65 from \( y \) so that the experiment would be for a case where it might be reasonable that you would be testing against 0. One does not typically test whether the mean income in the United States is zero or whether the mean blood pressure of live patients is zero. Had we left \( y \) as it was originally, we would have obtained \( z = 190 \) and \( z = 96 \). We did not want to show that comparison to you first because the mean of \( y \) is so far from 0 that you probably would never be testing it. The corresponding difference in \( \phi \) is tiny.

Regardless of the example, it is important that you base your tests in the metric where the likelihood surface is most quadratic. For further discussion on manipulability, see `Manipulability` in [R] `predictnl`.

This manipulability is not limited to Wald tests after estimation; you can also see the manipulability of results produced by linear regression just by applying nonlinear transforms to a covariate (Phillips and Park 1988; Gould 1996).

### Using margins after the estimates use command

Assume you fit and used `estimates save` (see [R] `estimates save`) to save the estimation results:

```
. regress y sex##group age c.age#c.age if site==1
. ....
. estimates save mymodel
   (file mymodel.ster saved)
```

Later, perhaps in a different Stata session, you reload the estimation results by typing

```
. estimates use mymodel
```

You plan to use `margins` with the reloaded results. You must remember that `margins` bases its results not only on the current estimation results but also on the current data in memory. Before you can use `margins`, you must reload the dataset on which you fit the model or, if you wish to produce standardized margins, some other dataset.

```
. use mydata, clear
   (data for fitting models)
```

If the dataset you loaded contained the data for standardization, you can stop reading; you know that to produce standardized margins, you need to specify the `nose` option.

We reloaded the original data and want to produce margins for the estimation sample. In addition to the data, `margins` requires that `e(sample)` be set, as `margins` will remind us:

```
. margins sex
e(sample) does not identify the estimation sample
   r(322);
```
The best solution is to use `estimates esample` to rebuild `e(sample)`:

```
. estimates esample: y sex group age if site==1
```

If we knew we had no missing values in `y` and the covariates, we could type

```
. estimates esample: if site==1
```

Either way, `margins` would now work:

```
. margins sex
  (usual output appears)
```

There is an alternative. We do not recommend it, but we admit that we have used it. Rather than rebuilding `e(sample)`, you can use `margins' noesample` option to tell `margins` to skip using `e(sample)`. You could then specify the appropriate `if` statement (if necessary) to identify the estimation sample:

```
. estimates use mymodel
. use mydata, clear
  (data for fitting models)
. margins sex if !missing(y, sex, group age) & site==1, noesample
  (usual output appears)
```

In the above, we are not really running on a sample different from the estimation sample; we are merely using `noesample` to fool `margins`, and then we are specifying on the `margins` command the conditions equivalent to re-create `e(sample)`.

If we wish to obtain `vce(unconditional)` results, however, `noesample` will be insufficient. We must also specify the `force` option,

```
. margins sex if !missing(y, sex, group age) & site==1,
 > vce(unconditional) noesample force
  (usual output appears)
```

Regardless of the approach you choose—resetting `e(sample)` or specifying `noesample` and possibly `force`—make sure you are right. In the `vce(delta)` case, you want to be right to ensure that you obtain the results you want. In the `vce(unconditional)` case, you need to be right because otherwise results will be statistically invalid.

**Syntax of at()**

In `at(atspec)`, `atspec` may contain one or more of the following specifications:

- `varlist`
  `(stat) varlist`
- `varname = #`
- `varname = (numlist)`
- `varname = generate(exp)`

where

1. `varnames` must be covariates in the previously fit model (estimation command).
2. Variable names (whether in `varname` or `varlist`) may be continuous variables, factor variables, or specific level variables, such as `age`, `group`, or `3.group`. 
3. `varlist` may also be one of three standard lists:
   a. `_all` (all covariates),
   b. `_factor` (all factor-variable covariates), or
   c. `continuous` (all continuous covariates).

4. Specifications are processed from left to right with latter specifications overriding previous ones.

5. `stat` can be any of the following:

<table>
<thead>
<tr>
<th>stat</th>
<th>Description</th>
<th>Variables allowed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>asobserved</code></td>
<td>at observed values in the sample</td>
<td>all</td>
</tr>
<tr>
<td><code>mean</code></td>
<td>means (default for <code>varlist</code>)</td>
<td>all</td>
</tr>
<tr>
<td><code>median</code></td>
<td>medians</td>
<td>continuous</td>
</tr>
<tr>
<td><code>p1</code></td>
<td>1st percentile</td>
<td>continuous</td>
</tr>
<tr>
<td><code>p2</code></td>
<td>2nd percentile</td>
<td>continuous</td>
</tr>
<tr>
<td><code>p50</code></td>
<td>50th percentile (same as <code>median</code>)</td>
<td>continuous</td>
</tr>
<tr>
<td><code>p98</code></td>
<td>98th percentile</td>
<td>continuous</td>
</tr>
<tr>
<td><code>p99</code></td>
<td>99th percentile</td>
<td>continuous</td>
</tr>
<tr>
<td><code>min</code></td>
<td>minimums</td>
<td>continuous</td>
</tr>
<tr>
<td><code>max</code></td>
<td>maximums</td>
<td>continuous</td>
</tr>
<tr>
<td><code>zero</code></td>
<td>fixed at zero</td>
<td>continuous</td>
</tr>
<tr>
<td><code>base</code></td>
<td>base level</td>
<td>factors</td>
</tr>
<tr>
<td><code>asbalanced</code></td>
<td>all levels equally probable and sum to 1</td>
<td>factors</td>
</tr>
</tbody>
</table>

Any `stat` except `zero`, `base`, and `asbalanced` may be prefixed with an `o` to get the overall statistic—the sample over all `over()` groups. For example, `omean`, `omedian`, and `op25`. Overall statistics differ from their correspondingly named statistics only when the `over()` or `within()` option is specified. When no `stat` is specified, `mean` is assumed.

**Estimation commands that may be used with margins**

`margins` may be used after most estimation commands.

`margins` cannot be used after estimation commands that do not produce full variance matrices, such as `exlogistic` and `expoisson` (see [R] `exlogistic` and [R] `expoisson`).

`margins` is all about covariates and cannot be used after estimation commands that do not post the covariates, which eliminates `gmm` (see [R] `gmm`).

`margins` cannot be used after estimation commands that have an odd data organization, and that excludes `asclogit`, `asmprobit`, `asroprobit`, and `nlogit` (see [R] `asclogit`, [R] `asmprobit`, [R] `asroprobit`, and [R] `nlogit`).
Video examples

Introduction to margins, part 1: Categorical variables
Introduction to margins, part 2: Continuous variables
Introduction to margins, part 3: Interactions

Glossary

**adjusted mean.** A *margin* when the response is the linear predictor from linear regression, ANOVA, etc. For some authors, adjusting also implies adjusting for unbalanced data. See *Obtaining margins of responses* and see *Obtaining margins as though the data were balanced.*

**average marginal effect.** See *marginal effect and average marginal effect.*

**average partial effect.** See *partial effect and average partial effect.*

**conditional margin.** A *margin* when the response is evaluated at fixed values of all the covariates. If any covariates are left to vary, the margin is called a predictive margin.

**effect.** The effect of \( x \) is the derivative of the response with respect to covariate \( x \), or it is the difference in responses caused by a discrete change in \( x \). Also see *marginal effect.*

The effect of \( x \) measures the change in the response for a change in \( x \). Derivatives or differences might be reported as elasticities. If \( x \) is continuous, the effect is measured continuously. If \( x \) is a factor, the effect is measured with respect to each level of the factor and may be calculated as a discrete difference or as a continuous change, as measured by the derivative. *margins* calculates the discrete difference by default and calculates the derivative if the *continuous* option is specified.

**elasticity** and *semielasticity.* The elasticity of \( y \) with respect to \( x \) is \( d(\ln y)/d(\ln x) = (x/y) \times (dy/dx) \), which is approximately equal to the proportional change in \( y \) for a proportional change in \( x \).

The semielasticity of \( y \) with respect to \( x \) is either 1) \( dy/d(\ln x) = x \times (dy/dx) \) or 2) \( d(\ln y)/dx = (1/y) \times (dy/dx) \), which is approximately 1) the change in \( y \) for a proportional change in \( x \) or 2) the proportional change in \( y \) for a change in \( x \).

**empty cell.** An interaction of levels of two or more factor variables for which you have no data. For instance, you have sex interacted with group in your model, and in your data there are no females in group 1. Empty cells affect which margins can be estimated; see *Estimability of margins.*

**estimability.** Estimability concerns whether a margin can be uniquely estimated (identified); see *Estimability of margins.*

**estimated marginal mean.** This is one of the few terms that has the same meaning across authors. An estimated marginal mean is a margin assuming the levels of each factor covariate are equally likely (balanced), including interaction terms. This is obtained using *margins’ asbalanced* option. In addition, there is an alternate definition of estimated marginal mean in which margins involving empty cells are redefined so that they become estimable. This is invoked by *margins’ emptycells(reweight) option.* See *Balancing in the presence of empty cells.*

**least-squares mean.** Synonym for *estimated marginal mean.*

**margin.** A statistic calculated from predictions or other statistics of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates. The prediction or other statistic on which the margin is based is called the response.

If all the covariates are fixed, then the margin is called a conditional margin. If any covariates are left to vary, the margin is called a predictive margin.
In this documentation, we divide margins on the basis of whether the statistic is a response or a derivative of a response; see *Obtaining margins of responses* and *Obtaining margins of derivatives of responses*.

**marginal effect** and **average marginal effect**. The marginal effect of $x$ is the *margin* of the *effect* of $x$. The term is popular with social scientists, and because of that, you might think the word marginal in marginal effect means derivative because of terms like marginal cost and marginal revenue. Marginal used in that way, however, refers to the derivative of revenue and the derivative of cost; it refers to the numerator, whereas marginal effect refers to the denominator. Moreover, *effect* is already a derivative or difference.

Some researchers interpret marginal in marginal effect to mean instantaneous, and thus a marginal effect is the instantaneous derivative rather than the discrete first-difference, corresponding to *margins*’ continuous option. Researchers who use marginal in this way refer to the discrete difference calculation of an effect as a partial effect.

Other researchers define marginal effect to be the margin when all covariates are held fixed and the average marginal effect when some covariates are not fixed.

**out-of-sample prediction**. Predictions made in one dataset using the results from a model fit on another. Sample here refers to the sample on which the model was fit, and out-of-sample refers to the dataset on which the predictions are made.

**partial effect** and **average partial effect**. Some authors restrict the term *marginal effect* to mean derivatives and use the term partial effect to denote discrete differences; see *marginal effect and average marginal effect*.

**population marginal mean**. The theoretical (true) value that is estimated by *estimated marginal mean*. We avoid this term because it can be confused with the concept of a population in survey statistics, with which the population marginal mean has no connection.

**posting results, posting margins**. A Stata concept having to do with storing the results from the *margins* command in $e()$ so that those results can be used as if they were estimation results, thus allowing the subsequent use of postestimation commands, such as test, testnl, lincom, and nlcom (see *R* test, *R* testnl, *R* lincom, and *R* nlcom). This is achieved by specifying *margins*’ post option. See *Example 10: Testing margins—contrasts of margins*.

**predictive margin**. A *margin* in which all the covariates are not fixed. When all covariates are fixed, it is called a *conditional margin*.

**recycled prediction**. A synonym for *predictive margin*.

**response**. A prediction or other statistic derived from combining the parameter estimates of a fitted model with data or specified values on covariates. Derivatives of responses are themselves responses. Responses are what we take *margins* of.

**standardized margin**. The margin calculated on data different from the data used to fit the model. The term standardized is usually reserved for situations in which the alternate population is a reference population, which may be real or artificial, and which is treated as fixed.

**subpopulation**. A subset of your sample that represents a subset of the population, such as the males in a sample of people. In survey contexts when it is desired to account for sampling of the covariates, standard errors for marginal statistics and effects need to account for both the population and the subpopulation. This is accomplished by specifying the *vce(unconditional)* option and one of the *subpop()* or *over()* options. In fact, the above is allowed even when your data are not *svyset* because *vce(unconditional)* implies that the sample represents a population.
Stored results

margins stores the following in \( r() \):

Scalars
- \( r(N) \): number of observations
- \( r(N_{sub}) \): subpopulation observations
- \( r(N_{clust}) \): number of clusters
- \( r(N_{psu}) \): number of sampled PSUs, survey data only
- \( r(N_{strata}) \): number of strata, survey data only
- \( r(df_R) \): variance degrees of freedom, survey data only
- \( r(N_{poststrata}) \): number of post strata, survey data only
- \( r(k_{predict}) \): number of \( predict() \) options
- \( r(k_{margins}) \): number of terms in \( marginlist \)
- \( r(k_{by}) \): number of subpopulations
- \( r(k_{at}) \): number of \( at() \) options
- \( r(level) \): confidence level of confidence intervals

Macros
- \( r(cmd) \): margins
- \( r(cmdline) \): command as typed
- \( r(est_{cmd}) \): \( e(cmd) \) from original estimation results
- \( r(est_{cmdline}) \): \( e(cmdline) \) from original estimation results
- \( r(title) \): title in output
- \( r(subpop) \): \( subspec \) from \( subpop() \)
- \( r(model_{vce}) \): \( vcetype \) from estimation command
- \( r(model_{vcetype}) \): Std. Err. title from estimation command
- \( r(vce) \): \( vcetype \) specified in \( vce() \)
- \( r(vcetype) \): title used to label Std. Err.
- \( r(clustvar) \): name of cluster variable
- \( r(margins) \): \( marginlist \)
- \( r(predict_{#_opts}) \): the \( # \)th \( predict() \) option
- \( r(predict_{#_label}) \): label from the \( # \)th \( predict() \) option
- \( r(expression) \): response expression
- \( r(xvars) \): \( varlist \) from \( dydx() \), \( dyex() \), \( eydx() \), or \( eyex() \)
- \( r(derivatives) \): “\( " \)”, “\( dy/dx \)”, “\( dy/ex \)”, “\( ey/dx \)”, “\( ey/ex \)”
- \( r(over) \): \( varlist \) from \( over() \)
- \( r(within) \): \( varlist \) from \( within() \)
- \( r(by) \): union of \( r(over) \) and \( r(within) \) lists
- \( r(by#) \): interaction notation identifying the \( # \)th subpopulation
- \( r(atstats#) \): the \( # \)th \( at() \) specification
- \( r(emptycells) \): \( empspec \) from \( emptycells() \)
- \( r(mcmethod) \): \( method \) from \( mcompare() \)
- \( r(mcadjustall) \): adjustall or empty

Matrices
- \( r(b) \): estimates
- \( r(V) \): variance–covariance matrix of the estimates
- \( r(Jacobian) \): Jacobian matrix
- \( r(_N) \): sample size corresponding to each margin estimate
- \( r(at) \): matrix of values from the \( at() \) options
- \( r(chainrule) \): chain rule information from the fitted model
- \( r(error) \): margin estimability codes;
  - 0 means estimable,
  - 8 means not estimable
- \( r(table) \): matrix containing the margins with their standard errors, test statistics, \( p \)-values, and confidence intervals
Margins with the `post` option also stores the following in `e()`:

Scalars
- `e(N)` number of observations
- `e(N_sub)` subpopulation observations
- `e(N_clust)` number of clusters
- `e(N_psu)` number of sampled PSUs, survey data only
- `e(N_strata)` number of strata, survey data only
- `e(df_r)` variance degrees of freedom, survey data only
- `e(N_poststrata)` number of post strata, survey data only
- `e(k_predict)` number of `predict()` options
- `e(k_margins)` number of terms in `marginlist`
- `e(k_by)` number of subpopulations
- `e(k_at)` number of `at()` options

Macros
- `e(cmd)` `margins`
- `e(cmdline)` command as typed
- `e(est_cmd)` `e(cmd)` from original estimation results
- `e(est_cmdline)` `e(cmdline)` from original estimation results
- `e(title)` title in estimation output
- `e(subpop)` `subspec` from `subpop()`
- `e(model_vce)` `vcetype` from estimation command
- `e(model_vcetype)` Std. Err. title from estimation command
- `e(vce)` `vcetype` specified in `vce()`
- `e(vcetype)` title used to label Std. Err.
- `e(clustvar)` name of cluster variable
- `e(margins)` `marginlist`
- `e(predict_##_opts)` the `#`th `predict()` option
- `e(predict_##_label)` label from the `#`th `predict()` option
- `e(expression)` prediction expression
- `e(xvars)` `varlist` from `dydx()`, `dyex()`, `eydx()`, or `eyex()`
- `e(derivatives)` “dy/dx”, “dy/ex”, “ey/dx”, “ey/ex”
- `e(over)` `varlist` from `over()`
- `e(within)` `varlist` from `within()`
- `e(by)` union of `r(over)` and `r(within)` lists
- `e(by#)` interaction notation identifying the `#`th subpopulation
- `e(atstats##)` the `#`th `at()` specification
- `e(emptycells)` `empspec` from `emptycells()`
- `e(mcompare)` `method` from `mcompare()`
- `e(mcompareall)` adjustall or empty

Matrices
- `e(b)` estimates
- `e(V)` variance–covariance matrix of the estimates
- `e(Jacobian)` Jacobian matrix
- `e(N)` sample size corresponding to each margin estimate
- `e(at)` matrix of values from the `at()` options
- `e(chainrule)` chain rule information from the fitted model

Functions
- `e(sample)` marks estimation sample

Methods and formulas

Margins are statistics calculated from predictions of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates. There are many names for the different statistics that margins can compute: estimates marginal means (see Searle, Speed, and Milliken [1980]), predictive margins (see Graubard and Korn [2004]), marginal effects (see Greene [2012]), and average marginal/partial effects (see Wooldridge [2010] and Bartus [2005]).
Methods and formulas are presented under the following headings:

Notation
Marginal effects
Fixing covariates and balancing factors
Estimable functions
Standard errors conditional on the covariates
Unconditional standard errors

Notation

Let \( \theta \) be the vector of parameters in the current model fit, let \( z \) be a vector of covariate values, and let \( f(z, \theta) \) be a scalar-valued function returning the value of the predictions of interest. The following table illustrates the parameters and default prediction for several of Stata’s estimation commands.

<table>
<thead>
<tr>
<th>Command</th>
<th>( \theta )</th>
<th>( z )</th>
<th>( f(z, \theta) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>regress</td>
<td>( \beta )</td>
<td>( x )</td>
<td>( x \beta )</td>
</tr>
<tr>
<td>cloglog</td>
<td>( \beta )</td>
<td>( x )</td>
<td>( 1 - e^{-x\beta} )</td>
</tr>
<tr>
<td>logit</td>
<td>( \beta )</td>
<td>( x )</td>
<td>( 1/(1 + e^{-x\beta}) )</td>
</tr>
<tr>
<td>poisson</td>
<td>( \beta )</td>
<td>( x )</td>
<td>( e^{x\beta} )</td>
</tr>
<tr>
<td>probit</td>
<td>( \beta )</td>
<td>( x )</td>
<td>( \Phi(x\beta) )</td>
</tr>
<tr>
<td>biprobit</td>
<td>( \beta_1, \beta_2, \rho )</td>
<td>( x_1, x_2 )</td>
<td>( \Phi_2(x_1, \beta_1, x_2, \beta_2, \rho) )</td>
</tr>
<tr>
<td>mlogit</td>
<td>( \beta_1, \beta_2, \ldots, \beta_k )</td>
<td>( x )</td>
<td>( e^{-x\beta_1}/(\sum_i e^{-x\beta_i}) )</td>
</tr>
<tr>
<td>nbreg</td>
<td>( \beta, \ln \alpha )</td>
<td>( x )</td>
<td>( e^{x\beta} \Phi() )</td>
</tr>
</tbody>
</table>

\( \Phi() \) and \( \Phi_2() \) are cumulative distribution functions: \( \Phi() \) for the standard normal distribution and \( \Phi_2() \) for the standard bivariate normal distribution.

margins computes estimates of

\[
p(\theta) = \frac{1}{M_{S_p}} \sum_{j=1}^{M} \delta_j(S_p) f(z_j, \theta)
\]

where \( \delta_j(S_p) \) identifies elements within the subpopulation \( S_p \) (for the prediction of interest),

\[
\delta_j(S_p) = \begin{cases} 
1, & j \in S_p \\
0, & j \notin S_p 
\end{cases}
\]

\( M_{S_p} \) is the subpopulation size,

\[
M_{S_p} = \sum_{j=1}^{M} \delta_j(S_p)
\]

and \( M \) is the population size.

Let \( \hat{\theta} \) be the vector of parameter estimates. Then margins estimates \( p(\theta) \) via

\[
\hat{p} = \frac{1}{w} \sum_{j=1}^{N} \delta_j(S_p) w_j f(z_j, \hat{\theta})
\]
where

\[ w_\cdot = \sum_{j=1}^{N} \delta_j(S_p)w_j \]

\( \delta_j(S_p) \) indicates whether observation \( j \) is in subpopulation \( S_p \), \( w_j \) is the weight for the \( j \)th observation, and \( N \) is the sample size.

**Marginal effects**

`margins` also computes marginal/partial effects. For the marginal effect of continuous covariate \( x \), `margins` computes

\[ \hat{p} = \frac{1}{w_\cdot} \sum_{j=1}^{N} \delta_j(S_p)w_j h(z_j, \hat{\theta}) \]

where

\[ h(z, \theta) = \frac{\partial f(z, \theta)}{\partial x} \]

The marginal effect for level \( k \) of factor variable \( A \) is the simple contrast (a.k.a. difference) comparing its margin with the margin at the base level.

\[ h(z, \theta) = f(z, \theta|A=k) - f(z, \theta|A=\text{base}) \]

**Fixing covariates and balancing factors**

`margins` controls the values in each \( z \) vector through the `marginlist`, the `at()` option, the `atmeans` option, and the `asbalanced` and `emptycells()` options. Suppose \( z \) is composed of the elements from the equation specification

\[ A##B x \]

where \( A \) is a factor variable with \( a \) levels, \( B \) is a factor variable with \( b \) levels, and \( x \) is a continuous covariate. To simplify the notation for this discussion, assume the levels of \( A \) and \( B \) start with 1 and are contiguous. Then

\[ z = (A_1, \ldots, A_a, B_1, \ldots, B_b, A_1B_1, A_1B_2, \ldots, A_aB_b, x, 1) \]

where \( A_i, B_j, \) and \( A_iB_j \) represent the indicator values for the factor variables \( A \) and \( B \) and the interaction \( A#B \).

When factor \( A \) is in the `marginlist`, `margins` replaces \( A \) with \( i \) and then computes the mean of the subsequent prediction, for \( i = 1, \ldots, a \). When the interaction term \( A#B \) is in the `marginlist`, `margins` replaces \( A \) with \( i \) and \( B \) with \( j \), and then computes the mean of the subsequent prediction, for all combinations of \( i = 1, \ldots, a \) and \( j = 1, \ldots, b \).
The \texttt{at()} option sets model covariates to fixed values. For example, \texttt{at(x=15)} causes \texttt{margins} to temporarily set \textit{x} to 15 for each observation in the dataset before computing any predictions. Similarly, \texttt{at((median) x)} causes \texttt{margins} to temporarily set \textit{x} to the median of \textit{x} using the current dataset.

When factor variable \textit{A} is specified as \texttt{asbalanced}, \texttt{margins} sets each \textit{A}_i to \(1/a\). Thus each \textit{z} vector will look like

\[
\mathbf{z} = (1/a, \ldots, 1/a, B_1, \ldots, B_b, B_1/a, B_2/a, \ldots, B_b/a, x, 1)
\]

If \textit{B} is also specified as \texttt{asbalanced}, then each \textit{B}_j is set to \(1/b\), and each \textit{z} vector will look like

\[
\mathbf{z} = (1/a, \ldots, 1/a, 1/b, \ldots, 1/b, 1/ab, 1/ab, \ldots, 1/ab, x, 1)
\]

If \texttt{emptycells(reweight)} is also specified, then \texttt{margins} uses a different balancing weight for each element of \textit{z}, depending on how many empty cells the element is associated with. Let \(\delta_{ij}\) indicate that the \(ij\)th cell of \textit{A}\#\textit{B} was observed in the estimation sample.

\[
\delta_{ij} = \begin{cases} 0, & \text{A = i and B = j was an empty cell} \\ 1, & \text{otherwise} \end{cases}
\]

For the grand margin, the affected elements of \textit{z} and their corresponding balancing weights are

\[
A_i = \frac{\sum_j \delta_{ij}}{\sum_k \sum_j \delta_{kj}}
\]

\[
B_j = \frac{\sum_i \delta_{ij}}{\sum_i \sum_k \delta_{ik}}
\]

\[
A_i B_j = \frac{\delta_{ij}}{\sum_k \sum_l \delta_{kl}}
\]

For the \(j\)th margin of \textit{B}, the affected elements of \textit{z} and their corresponding balancing weights are

\[
A_i = \frac{\delta_{ij}}{\sum_k \delta_{kj}}
\]

\[
B_l = \begin{cases} 1, & \text{if } l = j \text{ and not all } \delta_{ij} \text{ are zero} \\ 0, & \text{otherwise} \end{cases}
\]

\[
A_i B_l = \frac{\delta_{il}}{\sum_k \delta_{kl}} B_l
\]
Estimable functions

The fundamental idea behind estimable functions is clearly defined in the statistical literature for linear models; see Searle (1971). Assume that we are working with the following linear model:

\[ y = Xb + e \]

where \( y \) is an \( N \times 1 \) vector of responses, \( X \) is an \( N \times p \) matrix of covariate values, \( b \) is a \( p \times 1 \) vector of coefficients, and \( e \) is a vector of random errors. Assuming a constant variance for the random errors, the normal equations for the least-squares estimator, \( \hat{b} \), are

\[ X'X\hat{b} = X'y \]

When \( X \) is not of full column rank, we will need a generalized inverse (g-inverse) of \( X'X \) to solve for \( \hat{b} \). Let \( G \) be a g-inverse of \( X'X \).

Searle (1971) defines a linear function of the parameters as estimable if it is identically equal to some linear function of the expected values of the \( y \) vector. Let \( H = GX'X \). Then this definition simplifies to the following rule:

\[ zb \text{ is estimable if } z = zH \]

margins generalizes this to nonlinear functions by assuming the prediction function \( f(z, \theta) \) is a function of one or more of the linear predictions from the equations in the model that \( \theta \) represents.

\[ f(z, \theta) = h(z_1\beta_1, z_2\beta_2, \ldots, z_k\beta_k) \]

\( z_i\beta_i \) is considered estimable if \( z_i = z_iH_i \), where \( H_i = G_iX'_iX_i \), \( G_i \) is a g-inverse for \( X'_iX_i \), and \( X_i \) is the matrix of covariates from the \( i \)th equation of the fitted model. margins considers \( p(\theta) \) to be estimable if every \( z_i\beta_i \) is estimable.

Standard errors conditional on the covariates

By default, margins uses the delta method to estimate the variance of \( \hat{p} \).

\[ \hat{\text{Var}}(\hat{p} \mid z) = v'Vv \]

where \( V \) is a variance estimate for \( \hat{\theta} \) and

\[ v = \frac{\partial \hat{p}}{\partial \theta} \bigg|_{\theta = \hat{\theta}} \]

This variance estimate is conditional on the \( z \) vectors used to compute the marginalized predictions.
Unconditional standard errors

`margins` with the `vce(unconditional)` option uses linearization to estimate the unconditional variance of $\hat{\theta}$. Linearization uses the variance estimator for the total of a score variable for $\hat{p}$ as an approximate estimator for $\text{Var}(\hat{p})$; see [SVY] variance estimation. `margins` requires that the model was fit using some form of linearized variance estimator and that `predict, scores` computes the appropriate score values for the linearized variance estimator.

The score for $\hat{p}$ from the $j$th observation is given by

$$s_j = \frac{\partial \hat{p}}{\partial w_j} = -\frac{\delta_j(S_p)}{w.} \hat{p} + \frac{\delta_j(S_p)}{w.} f(z_j, \hat{\theta}) + \frac{1}{w} \sum_{i=1}^{N} \delta_i(S_p) w_i \frac{\partial f(z_i, \hat{\theta})}{\partial w_j}$$

The remaining partial derivative can be decomposed using the chain rule.

$$\frac{\partial f(z_i, \hat{\theta})}{\partial w_j} = \left( \frac{\partial f(z_i, \theta)}{\partial \theta} \bigg|_{\theta=\hat{\theta}} \right) \left( \frac{\partial \hat{\theta}}{\partial w_j} \right)'$$

This is the inner product of two vectors, the second of which is not a function of the $i$ index. Thus the score is

$$s_j = -\frac{\delta_j(S_p)}{w.} \hat{p} + \frac{\delta_j(S_p)}{w.} f(z_j, \hat{\theta}) + \left( \frac{\partial \hat{\theta}}{\partial \theta} \bigg|_{\theta=\hat{\theta}} \right) \left( \frac{\partial \hat{\theta}}{\partial w_j} \right)'$$

If $\hat{\theta}$ was derived from a system of equations (such as in linear regression or maximum likelihood estimation), then $\hat{\theta}$ is the solution to

$$G(\theta) = \sum_{j=1}^{N} \delta_j(S_m) w_j g(\theta, y_j, x_j) = 0$$

where $S_m$ identifies the subpopulation used to fit the model, $g()$ is the model’s gradient function, and $y_j$ and $x_j$ are the values of the dependent and independent variables for the $j$th observation. We can use linearization to derive a first-order approximation for $\partial \hat{\theta}/\partial w_j$.

$$G(\hat{\theta}) \approx G(\theta_0) + \left. \frac{\partial G(\theta)}{\partial \theta} \right|_{\theta=\theta_0} (\hat{\theta} - \theta_0)$$

Let $H$ be the Hessian matrix

$$H = \left. \frac{\partial G(\theta)}{\partial \theta} \right|_{\theta=\theta_0}$$

Then

$$\hat{\theta} \approx \theta_0 + (-H)^{-1} G(\theta_0)$$
and

$$\frac{\partial \hat{\theta}}{\partial w_j} \approx (\mathbf{-H})^{-1} \left. \frac{\partial G(\theta)}{\partial w_j} \right|_{\theta = \hat{\theta}} = (\mathbf{-H})^{-1} \delta_j(S_m) g(\hat{\theta}, y_j, x_j)$$

The computed value of the score for \( \hat{p} \) for the \( j \)th observation is

$$s_j = v' u_j$$

where

$$v = \begin{bmatrix} \frac{\hat{p}}{w} \\ \frac{1}{w} \\ \frac{\partial \hat{p}}{\partial \theta} (\mathbf{-H})^{-1} \end{bmatrix}$$

and

$$u_j = \begin{bmatrix} \delta_j(S_p) \\ \delta_j(S_p) f(z_j, \hat{\theta}) \\ \delta_j(S_m) g(\hat{\theta}, y_j, x_j) \end{bmatrix}$$

Thus the variance estimate for \( \hat{p} \) is

$$\hat{\text{Var}}(\hat{p}) = v' \hat{\text{Var}}(\hat{U}) v$$

where

$$\hat{U} = \sum_{j=1}^{N} w_j u_j$$

margins uses the model-based variance estimates for \((\mathbf{-H})^{-1}\) and the scores from predict for \( g(\hat{\theta}, y_j, x_j) \).

Remarks and examples

Continuing with the example from Example 8: Margins of interactions in [R] margins, we use the dataset and reestimate the logistic model of outcome:

```
. use http://www.stata-press.com/data/r14/margex
(Artificial data for margins)
. logistic outcome sex##group age
(output omitted)
```

1416
We then estimate the margins for males and females and post the margins as estimation results with a full VCE.

```
. margins sex, post
```

**Predictive margins**

Number of obs = 3,000

Model VCE : OIM

Expression : Pr(outcome), predict()

| Delta-method   | Margin | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|----------------|--------|-----------|------|------|----------------------|
| sex            |        |           |      |      |                      |
| male           | .1600644 | .0125653 | 12.74 | 0.000 | .1354368 .184692 |
| female         | .1966902 | .0100043 | 19.66 | 0.000 | .1770821 .2162983 |

We can now use `nlcom` (see [R] `nlcom`) to estimate a risk ratio of females to males using the average probabilities for females and males posted by `margins`:

```
. nlcom (risk_ratio: _b[1.sex] / _b[0.sex])
```

| Coef. | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|-------|-----------|------|------|----------------------|
| risk_ratio | 1.228819 | .1149538 | 10.69 | 0.000 | 1.003514 1.454124 |

We could similarly estimate the average risk difference between females and males:

```
. nlcom (risk_diff: _b[1.sex] - _b[0.sex])
```

| Coef. | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|-------|-----------|------|------|----------------------|
| risk_diff | .0366258 | .0160632 | 2.28 | 0.023 | .0051425 .068109 |

[U] 20 Estimation and postestimation commands
margins, contrast — Contrasts of margins

Description

margins with the contrast option or with contrast operators performs contrasts of margins. This extends the capabilities of contrast to any of the nonlinear responses, predictive margins, or other margins that can be estimated by margins.

Quick start

Reference category contrasts of the predictive margins for a after logit y a##b x1
margins r.a

Contrasts of predictive margins for a with the previous level
margins ar.a

Test the equality of predictive margins for a
margins a, contrast

Reference category contrasts of predictive margins for x1 = 10 and x1 = 20 with x1 = 0
margins, at(x1=(0 10 20)) contrast(atcontrast(r))

Average partial effect of increasing x1 by 100 for each observation after probit y x1 x2
margins, at((asobserved) _all) at(x1=generate(x1+100)) ///
contrast(atcontrast(r))

Menu

Statistics > Postestimation
Syntax

`margins [marginlist] [if] [in] [weight] [, contrast margins_options]`

`margins [marginlist] [if] [in] [weight] [, contrast(suboptions) margins_options]`

where `marginlist` is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without contrast operators, and you may use any factor-variable syntax:

```
. margins sex##group, contrast
. margins sex##g.group, contrast
. margins sex@g.group, contrast
```

See the operators (op.) table in [R] contrast for the list of contrast operators. Contrast operators may also be specified on the variables in `margins`’s `over()` and `within()` options to perform contrasts across the levels of those variables.

</tbody>
</table>

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

Suboptions

| Contrast | overall specifies that a joint hypothesis test over all terms be performed. |
lincom specifies that user-defined contrasts be treated as linear combinations. The default is to require that all user-defined contrasts sum to zero. (Summing to zero is part of the definition of a contrast.)

predict(op[...predict]) specifies that the op. contrast operator be applied to the groups defined by multiple specifications of margins's predict() option. The default behavior, by comparison, is to perform tests and contrasts within these groups.

atcontrast(op[...at]) specifies that the op. contrast operator be applied to the groups defined by the at() option(s). The default behavior, by comparison, is to perform tests and contrasts within the groups defined by the at() option(s).

See example 6 in Remarks and examples.

predictjoint specifies that joint tests be performed across all groups defined by multiple specifications of margins's predict() option. The default behavior, by comparison, is to perform contrasts and tests within each group.

atjoint specifies that joint tests be performed across all groups defined by the at() option. The default behavior, by comparison, is to perform contrasts and tests within each group.

See example 5 in Remarks and examples.

overjoint specifies how unoperated variables in the over() option are treated.

Each variable in the over() option may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.

overjoint specifies that joint tests be performed across all levels of the unoperated variables. The default behavior, by comparison, is to perform contrasts and tests within each combination of levels of the unoperated variables.

See example 3 in Remarks and examples.

withinjoint specifies how unoperated variables in the within() option are treated.

Each variable in the within() option may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.

withinjoint specifies that joint tests be performed across all levels of the unoperated variables. The default behavior, by comparison, is to perform contrasts and tests within each combination of levels of the unoperated variables.

marginswithin specifies how unoperated variables in marginlist are treated.

Each variable in marginlist may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.

marginswithin specifies that contrasts and tests be performed within each combination of levels of the unoperated variables. The default behavior, by comparison, is to perform joint tests across all levels of the unoperated variables.

See example 4 in Remarks and examples.

cieffects specifies that a table containing a confidence interval for each individual contrast be reported.

pveffects specifies that a table containing a p-value for each individual contrast be reported.

effects specifies that a single table containing a confidence interval and p-value for each individual contrast be reported.

nowald suppresses the table of Wald tests.
Remarks and examples

Remarks are presented under the following headings:

- Contrasts of margins
- Contrasts and the over() option
  - The overjoint suboption
  - The marginswithin suboption
- Contrasts and the at() option
- Estimating treatment effects with margins
- Conclusion

Contrasts of margins

Example 1

Estimating contrasts of margins is as easy as adding a contrast operator to the variable name. Let’s review Example 2: A simple case after logistic of [R] margins. Variable sex is coded 0 for males and 1 for females.

```stata
use http://www.stata-press.com/data/r14/margex
. logistic outcome i.sex i.group
(output omitted)
. margins sex
```

Predictive margins  Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()

|          | Delta-method | Margin | Std. Err. | z     | P>|z|   | [95% Conf. Interval] |
|----------|--------------|--------|-----------|-------|-------|---------------------|
| sex      |              |        |           |       |       |                     |
| male     | .1286796     | .0111424 | 11.55     | 0.000 | .000  | .106841 .1505182   |
| female   | .1905087     | .0089719 | 21.23     | 0.000 | .000  | .1729241 .2080933  |
```

The first margin, 0.13, is the average probability of a positive outcome, treating everyone as if they were male. The second margin, 0.19, is the average probability of a positive outcome, treating everyone as if they were female. We can compare females with males by rerunning margins and adding a contrast operator:
The `r.` prefix for `sex` is the reference-category contrast operator—see [R] `contrast`. (The default reference category is zero, the lowest value of `sex`.) Contrast operators in a `marginlist` work just as they do in the `termlist` of a `contrast` command.

The contrast estimate of 0.06 says that unconditional on group, females on average are about 6% more likely than males to have a positive outcome. The chi-squared statistic of 16.61 shows that the contrast is significantly different from zero.

You may be surprised that we did not need to include the `contrast` option to estimate our contrast. If we had included the option, our output would not have changed:

```
 margins r.sex, contrast
```

The `contrast` option is useful mostly for its suboptions, which control the output and how contrasts are estimated in more complicated situations. But `contrast` may be specified on its own (without contrast operators or suboptions) if we do not need estimates or confidence intervals:

```
 margins sex group, contrast
```

The contrast estimate of 0.06 says that unconditional on group, females on average are about 6% more likely than males to have a positive outcome. The chi-squared statistic of 16.61 shows that the contrast is significantly different from zero.
Each chi-squared statistic is a joint test of constituent contrasts. The test for group has two degrees of freedom because group has three levels.

### Contrasts and the over() option

#### Example 2

It is common to estimate margins at combinations of factor levels, and margins, contrast includes several suboptions for contrasting such margins. Let’s fit a model with two categorical predictors and their interaction:

```
. logistic outcome agegroup##group
```

| outcome | Odds Ratio | Std. Err. | z     | P>|z|   | [95% Conf. Interval] |
|---------|-----------|-----------|-------|-------|----------------------|
| agegroup |           |           |       |       |                      |
| 30-39   | 3.54191   | 2.226951  | 2.01  | 0.044 | 1.032882 12.14576    |
| 40+     | 16.23351  | 9.61168   | 4.71  | 0.000 | 5.086452 51.80955    |
| group   |           |           |       |       |                      |
| 2       | .834507   | .5663738  | -0.27 | 0.790 | .2206611 3.15598     |
| 3       | .2146729  | .1772897  | -1.86 | 0.062 | .0425407 1.083303    |
| agegroup# |         |           |       |       |                      |
| group   |           |           |       |       |                      |
| 30-39#2 | .4426927  | .3358505  | -1.07 | 0.283 | .1000772 1.958257    |
| 30-39#3 | 1.160885  | 1.103527  | 0.16  | 0.875 | .1801543 7.480553    |
| 40+#2   | .440672   | .3049393  | -1.18 | 0.236 | .1135259 1.71055     |
| 40+#3   | .4407912  | .4034688  | -0.89 | 0.371 | .0733 2.650709      |
| _cons   | .0379747  | .0223371  | -5.56 | 0.000 | .0119897 12.02762    |

Each of agegroup and group has three levels. To compare each age group with the reference category on the probability scale, we can again use margins with the r. contrast operator.
. margins r.agegroup

Contrasts of predictive margins
Model VCE : OIM

</tbody>
</table>

The effect of agegroup appears to be greatest for the first level of group.

Including a variable in the over() option is not equivalent to including the variable in the main marginlist. The variables in the marginlist are manipulated in the analysis, so that we can measure, for example, the effect of being in age group 3 and not age group 1. (The manipulation could be mimicked by running replace and then predict, but the manipulations actually performed by margins do not
change the data in memory.) The variables in the over() option are not so manipulated—the values of the over() variables are left as they were observed, and the marginlist variables are manipulated separately for each observed over() group.

The overjoint suboption

Example 3

Each variable in an over() option may be specified with or without contrast operators. Our option over(group) did not include a contrast operator, so margins estimated the contrasts separately for each level of group. If we had instead specified over(r.group), we would have received differences of the contrasts:

```
. margins r.agegroup, over(r.group)
```

Contrasts of predictive margins
Expression : Pr(outcome), predict()
over : group

<table>
<thead>

<tr>
<td>Joint</td>
<td>4</td>
<td>83.88</td>
<td>0.0000</td>
</tr>
</tbody>
</table>

The contrasts are double differences: the estimate of −0.19, for example, says that the difference in the probability of success between age group 3 and age group 1 is smaller in group 2 than in group 1. We can jointly test pairs of the double differences with the overjoint suboption:

```
. margins r.agegroup, over(group) contrast(overjoint)
```

Contrasts of predictive margins
Expression : Pr(outcome), predict()
over : group

<table>
<thead>
<tr>
<th></th>
<th>df</th>
<th>ch2</th>
<th>P&gt;ch2</th>
</tr>
</thead>
<tbody>
<tr>

<td>0.0000</td>
</tr>
<tr>
<td>Joint</td>
<td>4</td>
<td>83.88</td>
<td>0.0000</td>
</tr>
</tbody>
</table>
The \texttt{contrast(overjoint)} option overrides the default behavior of \texttt{over()} and requests joint tests over the levels of the unoperated variable \texttt{group}. The chi-squared statistic of 3.62 tests that the first and third contrasts from the previous table are jointly zero. The chi-squared statistic of 79.45 jointly tests the other pair of contrasts.

\section*{The \texttt{marginswithin} suboption}

\textbf{Example 4}

Another suboption that may usefully be combined with \texttt{over()} is \texttt{marginswithin}. \texttt{marginswithin} requests that contrasts be performed within the levels of unoperated variables in the main \texttt{marginlist}, instead of performing them jointly across the levels. \texttt{marginswithin} affects only unoperated variables because contrast operators take precedence over suboptions.

Let's first look at the default behavior, which occurs when \texttt{marginswithin} is not specified:

\begin{verbatim}
. margins agegroup, over(r.group) contrast(effects)
\end{verbatim}

Contrasts of predictive margins
Model VCE : OIM
Expression : Pr(outcome), predict()

\end{tabular}

Here \texttt{agegroup} in the main \texttt{marginlist} is an unoperated variable, so \texttt{margins} by default performs joint tests across the levels of \texttt{agegroup}: the chi-squared statistic of 33.94, for example, jointly tests whether the first two contrast estimates in the lower table differ significantly from zero.
When we specify `marginswithin`, the contrasts will instead be performed within the levels of `agegroup`:

```
margins agegroup, over(r.group) contrast(marginswithin effects)
```

### Contrasts of predictive margins

Model VCE: OIM

The joint tests in the top table have been replaced by one-degree-of-freedom tests, one for each combination of the two reference comparisons and three levels of `agegroup`. The reference-category contrasts for `group` have been performed within levels of `agegroup`.

### Contrasts and the at() option

**Example 5**

The `at()` option of `margins` is used to set predictors to particular values. When `at()` is used, contrasts are by default performed within each `at()` level:
Contrasts of adjusted predictions

Model VCE: OIM

Expression: \( \text{Pr(outcome)}, \text{predict()} \)

1._at: group = 1
2._at: group = 2
3._at: group = 3

<table>
<thead>
<tr>
<th>agegroup@_at</th>
<th>df</th>
<th>chi2</th>
<th>P&gt;chi2</th>
</tr>
</thead>
<tbody>
<tr>
<td>(30-39 vs 20-29) 1</td>
<td>1</td>
<td>6.94</td>
<td>0.0084</td>
</tr>
<tr>
<td>(30-39 vs 20-29) 2</td>
<td>1</td>
<td>1.18</td>
<td>0.2783</td>
</tr>
<tr>
<td>(30-39 vs 20-29) 3</td>
<td>1</td>
<td>3.10</td>
<td>0.0783</td>
</tr>
<tr>
<td>(40+ vs 20-29) 1</td>
<td>1</td>
<td>173.42</td>
<td>0.0000</td>
</tr>
<tr>
<td>(40+ vs 20-29) 2</td>
<td>1</td>
<td>57.77</td>
<td>0.0000</td>
</tr>
<tr>

<td>1</td>
<td>5.12</td>
<td>0.0236</td>
</tr>
<tr>
<td>Joint</td>
<td>6</td>
<td>266.84</td>
<td>0.0000</td>
</tr>
</tbody>
</table>

Joint

<table>
<thead>
<tr>
<th>_at#agegroup</th>
<th>df</th>
<th>chi2</th>
<th>P&gt;chi2</th>
</tr>
</thead>
<tbody>
<tr>
<td>(joint) (30-39 vs 20-29)</td>
<td>2</td>
<td>3.62</td>
<td>0.1641</td>
</tr>
<tr>
<td>(joint) (40+ vs 20-29)</td>
<td>2</td>
<td>79.45</td>
<td>0.0000</td>
</tr>
<tr>
<td>Joint</td>
<td>4</td>
<td>83.88</td>
<td>0.0000</td>
</tr>
</tbody>
</table>

Our option \( \text{at(group=(1/3))} \) manipulates the values of group and is therefore not equivalent to \( \text{over(group)} \). We see that the reference-category contrasts for agegroup have been performed within each \( \text{at()} \) level. For a similar example that uses the \( \_\text{at}() \) operator instead of the \text{at()} option, see \text{Contrasts of at()} groups—discrete effects in \text{[R] marginsplot}.

The default within behavior of \text{at()} may be changed to joint behavior with the \text{atjoint} suboption:

\[ \text{. margins r.agegroup, at(group=(1/3)) contrast(atjoint)} \]

Contrasts of adjusted predictions

Model VCE: OIM

Expression: \( \text{Pr(outcome)}, \text{predict()} \)

1._at: group = 1
2._at: group = 2
3._at: group = 3

<table>
<thead>
<tr>
<th>_at#agegroup</th>
<th>df</th>
<th>chi2</th>
<th>P&gt;chi2</th>
</tr>
</thead>
<tbody>
<tr>
<td>(joint) (30-39 vs 20-29)</td>
<td>2</td>
<td>3.62</td>
<td>0.1641</td>
</tr>
<tr>
<td>(joint) (40+ vs 20-29)</td>
<td>2</td>
<td>79.45</td>
<td>0.0000</td>
</tr>
<tr>
<td>Joint</td>
<td>4</td>
<td>83.88</td>
<td>0.0000</td>
</tr>
</tbody>
</table>

Now the tests are performed jointly over the levels of group, the \text{at()} variable. The \text{atjoint} suboption is the analogue for \text{at()} of the \text{overjoint} suboption from \text{example 3}.
Example 6

What if we would like to apply a contrast operator, like \( r \), to the at() levels? It is not possible to specify the operator inside the at() option. Instead, we need a new suboption, atcontrast():

```
. margins r.agegroup, at(group=(1/3)) contrast(atcontrast(r))
```

<table>
<thead>
<tr>
<th>Expression</th>
<th>df</th>
<th>chi2</th>
<th>P&gt;chi2</th>
</tr>
</thead>
<tbody>
<tr>
<td>_at#agegroup</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>(2 vs 1) (30-39 vs 20-29)</td>
<td>1</td>
<td>3.55</td>
<td>0.0596</td>
</tr>
<tr>
<td>(2 vs 1) (40+ vs 20-29)</td>
<td>1</td>
<td>33.17</td>
<td>0.0000</td>
</tr>
<tr>
<td>(3 vs 1) (30-39 vs 20-29)</td>
<td>1</td>
<td>2.86</td>
<td>0.0906</td>
</tr>
<tr>
<td>(3 vs 1) (40+ vs 20-29)</td>
<td>1</td>
<td>79.36</td>
<td>0.0000</td>
</tr>
<tr>
<td>Joint</td>
<td>4</td>
<td>83.88</td>
<td>0.0000</td>
</tr>
</tbody>
</table>

When we specify `contrast(atcontrast(r))`, `margins` will apply the \( r \) reference-category operator to the levels of group, the variable specified inside at(). The default reference category is 1, the lowest level of group.

Estimating treatment effects with margins

`margins` with the `contrast` option can also be used to estimate treatment effects in certain cases. A treatment effect represents the change in an outcome variable that is attributable to a particular event, controlling for all other factors that could affect the outcome. For example, we might want to know how a person’s wage changes as a result of being in a union. Here the outcome variable is the person’s wage, and the “event” is membership in a union. The treatment effect measures the difference in a person’s wage as a result of being or not being in a union once we control for the person’s educational background, level of experience, industry, and other factors.

In fact, Stata has an entire manual dedicated to estimators designed specifically for estimating treatment effects; see the `Stata Treatment-Effects Reference Manual`. Here we show how `margins` can be used to estimate treatment effects using the regression-adjustment estimator when the conditional independence assumption is met; see [TE] `teffects intro`. Regression adjustment simply means that we are going to use a regression model to predict the outcome variable, controlling for treatment status and other characteristics. The conditional independence assumption implies that we have enough variables in our dataset so that once we control for them in our regression model, the outcomes one would obtain with and without treatment are independent of how treatment status is determined.
Example 7: Regression adjustment with a binary treatment variable  

`nlsw88.dta` contains women’s wages (wage) in dollars per hour, a binary variable indicating their union status (union), years of experience (ttl_exp), and a variable, grade, indicating the number of years of schooling completed. We want to know how being in a union (the treatment) affects women’s wages. Traditionally, a wage equation of the form

\[
\ln \text{wage}_i = \beta_0 + \beta_1 \text{union}_i + \beta_2 \text{grade}_i + \beta_3 \text{ttl}\_exp + \beta_4 \text{ttl}\_exp^2 + \epsilon_i
\]

would be fit. However, there are two shortcomings that we will improve upon. First, to avoid the problem of predicting the level of a log-transformed dependent variable, we will use `poisson` with the `vce(robust)` option to fit an exponential regression model; see Wooldridge (2010, sec. 18.2) for background on this approach. Second, the previous equation implies that factors other than union status have the same impact on wages for both union and nonunion workers. Regression-adjustment estimators allow all the variables to have different impacts depending on the level of the treatment variable, and we can accomplish that here using factor-variable notation. In Stata, we fit our model by typing

```stata
. use http://www.stata-press.com/data/r14/nlsw88
(NLSW, 1988 extract)
. poisson wage i.union##(c.grade c.ttl_exp##c.ttl_exp), vce(robust)
   note: you are responsible for interpretation of noncount dep. variable
```

| Coef. | Std. Err. | z     | P>|z|   | [95% Conf. Interval] |
|-------|-----------|-------|-------|----------------------|

| union#c.ttl_exp#c.ttl_exp | .0011808 | .0008428 | 1.40  | 0.161                | -.0004711 .0028327 |
| _cons | .017488   | .0893602 | 0.20  | 0.845                | -.1576547 .1926308 |
To see how union status affects wages, we can use `margins`:

```
margins r.union, vce(unconditional)
```

**Contrasts of predictive margins**

Expression : Predicted number of events, `predict()`

<table>
<thead>
<tr>
<th></th>
<th>df</th>
<th>chi2</th>
<th>P&gt;chi2</th>
</tr>
</thead>
<tbody>
<tr>
<td>union</td>
<td>1</td>
<td>26.22</td>
<td>0.0000</td>
</tr>
</tbody>
</table>

```
<table>
<thead>
<tr>
<th>Contrast</th>
<th>Std. Err.</th>
<th>[95% Conf. Interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>union (union vs nonunion)</td>
<td>1.004119</td>
<td>.1960944 .6197815 1.388457</td>
</tr>
</tbody>
</table>
```

The estimated contrast 1.004 indicates that on average, belonging to a union causes a woman’s wage to be slightly more than a dollar higher than if she were not in the union. This estimated contrast is called the average treatment effect (ATE). Conceptually, we predicted the wage of each woman in the estimation sample assuming she was in a union and obtained the sample mean. We then predicted each woman’s wage assuming she was not in a union and obtained that sample mean. The difference between these two sample means represents the ATE.

We obtain essentially the same results by using `teffects ra`:

```
teffects ra (wage c.grade c.ttl_exp##c.ttl_exp, poisson) (union)
```

```
Iteration 0: EE criterion = 2.611e-13
Iteration 1: EE criterion = 1.112e-26
```

```
Treatment-effects estimation Number of obs = 1,876
Estimator : regression adjustment
Outcome model : Poisson
Treatment model: none
```

| wage | Coef. | Std. Err. | z | P>|z| | [95% Conf. Interval] |
|------|-------|-----------|---|-------|----------------------|
| ATE  | union (union vs nonunion) | 1.004119 | .1960421 | 5.12 | 0.000 | .619884 1.388355 |
| POmean | union nonunion | 7.346493 | .1096182 | 67.02 | 0.000 | 7.131645 7.561341 |

The point estimates of the ATE are identical to those we obtained using `margins`, though the standard errors differ slightly from those reported by `margins`. The standard errors from the two estimators are, however, asymptotically equivalent, meaning they would coincide with a sufficiently large dataset. The last statistic in this output table indicates the untreated potential-outcome mean (untreated POM), which is the mean predicted wage assuming each woman did not belong to a union.

If we specify the `pomeans` option with `teffects ra`, we can obtain both the treated and the untreated POMs, which represent the predicted mean wages assuming all women were or were not in the union:

Notice that the difference between these two POMs equals 1.004119, which is the ATE we obtained earlier.

In some applications, the average treatment effect of the treated (ATET) is more germane than the ATE. For example, if the untreated subjects in the sample could not possibly receive treatment (perhaps because a medical condition precludes their taking an experimental drug), then considering the counterfactual outcome had those subjects taken the drug may not be relevant. In these cases, the ATET is a better statistic because it measures the effect of the treatment only for those subjects who actually did receive treatment. Like the ATE, the ATET involves computing predicted outcomes for each treatment level, obtaining the sample means, and computing the difference between those two means. Unlike the ATE, however, we only use observations corresponding to treated subjects.

Example 8: Regression adjustment with a binary treatment variable (continued)

Here we calculate the ATET of union membership, first using margins. Because teffects ra overwrote our estimation results, we first quietly refit our poisson model. We then call margins to obtain the ATET:

```
. quietly poisson wage i.union##(c.grade c.ttl_exp##c.ttl_exp), vce(robust)
. margins r.union, subpop(union) vce(unconditional)
```

The key here was specifying the subpop(union) option to restrict margin’s computations to those women who are union members. The results indicate that being in the union causes the union members’ wages to be about 90 cents higher than they would otherwise be.
To replicate these results using `teffects ra`, we include the `atet` option to obtain ATETs:

```
. teffects ra (wage c.grade c.ttl_exp##c.ttl_exp, poisson) (union), atet
```

```
Iteration 0: EE criterion = 2.611e-13
Iteration 1: EE criterion = 9.347e-27
```

```
Treatment-effects estimation
Number of obs = 1,876
Estimator : regression adjustment
Outcome model : Poisson
Treatment model: none
```

```
| wage | Coef.  | Std. Err. | z     | P>|z|   | [95% Conf. Interval] |
|------|--------|-----------|-------|-------|---------------------|
| ATET |        |           |       |       |                     |
| union (union vs nonunion) | .901419 | .2075309 | 4.34  | 0.000  | .4946658 1.308172   |
| POmean |      |           |       |       |                     |
| union nonunion | 7.776417 | .162121 | 47.97 | 0.000  | 7.458665 8.094168  |
```

We obtain the same point estimate of the effect of union status as with `margins`. As before, the standard errors differ slightly between the two estimators, but they are asymptotically equivalent. The output also indicates that among the women who are in a union, their average wage would be $7.78 if they were not in a union.

─ Technical note ─

One advantage of the ATET over the ATE is that the ATET can be consistently estimated with slightly weaker assumptions than are required to consistently estimate the ATE. See *Comparing the ATE and ATET* in Remarks and examples of [TE] `teffects intro advanced`.

Both `margins` and `teffects` can estimate treatment effects using regression adjustment, so which should you use? In addition to regression adjustment, the `teffects` command implements other estimators of treatment effects; some of these estimators possess desirable robustness properties that we cannot replicate using `margins`. Moreover, all the `teffects` estimators use a common syntax and automatically present the estimated treatment effects, whereas we must first fit our own regression model and then call `margins` to obtain the treatment effects.

On the other hand, particularly with the `at()` option, `margins` gives us more flexibility in specifying our scenarios. The `teffects` commands allow us to measure the effect of a single binary or multinomial treatment, but we can have `margins` compute the effects of arbitrary interventions, as we illustrate in the next example.

### Example 9: Interventions involving multiple variables

Suppose we want to see how women’s wages would be affected if we could increase each woman’s education level by one year. That is, we want to measure the treatment effect of an additional year of schooling. We assume that if a woman attains another year of schooling, she cannot simultaneously work. Thus an additional year of education implies her total work experience must decrease by a year. The flexible `at()` option of `margins` allows us to manipulate both variables at once:
. quietly poisson wage i.union##(c.grade c.ttl_exp##c.ttl_exp), vce(robust)
. margins, at((asobserved) _all)
  > at(grade=generate(grade+1) ttl_exp=generate(ttl_exp-1))
  > contrast(atcontrast(r._at))

Contrasts of predictive margins
Model VCE : Robust
Expression : Predicted number of events, predict()
1._at : (asobserved)
2._at : grade = grade+1
     ttl_exp = ttl_exp-1

<table>
<thead>
<tr>
<th></th>
<th>df</th>
<th>chi2</th>
<th>P&gt;chi2</th>
</tr>
</thead>
<tbody>
<tr>
<td>_at</td>
<td>1</td>
<td>58.53</td>
<td>0.0000</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>Delta-method</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Contrast</td>
</tr>
<tr>
<td>_at</td>
<td>(2 vs 1)</td>
</tr>
</tbody>
</table>
<pre><code>  |              | .2521813   | .4258971         |
</code></pre>

The first at() option instructs margins to obtain predicted wages for all women in the sample using their existing values for grade and ttl_exp and to record the mean of those predictions. The second at() option instructs margins to obtain the mean predicted wage under the counterfactual scenario where each woman’s education level is increased by one year and total work experience is simultaneously decreased by one year. The contrast() option instructs margins to compute the difference between the two means. The output indicates that increasing education by one year, which will necessarily decrease work experience by the same amount, will cause the average wage to increase by about 34 cents per hour, a statistically significant amount.

Conclusion

margins, contrast is a powerful command, and its abundance of suboptions may seem daunting. The suboptions are in the service of only three goals, however. There are three things that margins, contrast can do with a factor variable or a set of at() definitions:
1. Perform contrasts across the levels of the factor or set (as in example 1).
2. Perform a joint test across the levels of the factor or set (as in example 5).
3. Perform other tests and contrasts within each level of the factor or set (as in example 4).

The default behavior for variables specified inside at(), over(), and within() is to perform contrasts within groups; the default behavior for variables in the marginlist is to perform joint tests across groups.
Stored results

`margins, contrast` stores the following additional results in `r()`:

Scalars
- `r(k_terms)`: number of terms participating in contrasts

Macros
- `r(cmd)`: contrast
- `r(cmd2)`: margins
- `r(overall)`: overall or empty

Matrices
- `r(L)`: matrix of contrasts applied to the margins
- `r(chi2)`: vector of $\chi^2$ statistics
- `r(p)`: vector of $p$-values corresponding to `r(chi2)`
- `r(df)`: vector of degrees of freedom corresponding to `r(p)`

`margins, contrast` with the `post` option also stores the following additional results in `e()`:

Scalars
- `e(k_terms)`: number of terms participating in contrasts

Macros
- `e(cmd)`: contrast
- `e(cmd2)`: margins
- `e(overall)`: overall or empty

Matrices
- `e(L)`: matrix of contrasts applied to the margins
- `e(chi2)`: vector of $\chi^2$ statistics
- `e(p)`: vector of $p$-values corresponding to `e(chi2)`
- `e(df)`: vector of degrees of freedom corresponding to `e(p)`

Methods and formulas

See `Methods and formulas` in `[R] margins` and `Methods and formulas` in `[R] contrast`.

[R] margins, pwcompare — Pairwise comparisons of margins
[R] pwcompare — Pairwise comparisons
## margins, pwcompare — Pairwise comparisons of margins

### Description

`margins` with the `pwcompare` option performs pairwise comparisons of margins. `margins, pwcompare` extends the capabilities of `pwcompare` to any of the nonlinear responses, predictive margins, or other margins that can be estimated by `margins`.

### Quick start

All pairwise comparisons of the predictive margins for `a` after `logit y a##b x1`

```
margins a, pwcompare
```

As above, but report both tests and confidence intervals for differences in predictive margins

```
margins a, pwcompare(effects)
```

As above, but adjust $p$-values and confidence intervals for multiple comparisons using Bonferroni’s method

```
margins a, pwcompare(effects) mcompare(bonferroni)
```

Report predictive margins for the levels of `a`, and group those that are not significantly different

```
margins a, pwcompare(groups)
```

All pairwise comparisons of the predictive margins for combinations of levels of `a` and `b`

```
margins a#b, pwcompare
```

### Menu

Statistics  >  Postestimation
Syntax

margins [marginlist] [if] [in] [weight] [, pwcompare margins_options]
margins [marginlist] [if] [in] [weight] [ , pwcompare(suboptions) margins_options]

where marginlist is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without the i. prefix, and you may use any factor-variable syntax:

. margins i.sex i.group i.sex#i.group, pwcompare
. margins sex group sex#i.group, pwcompare
. margins sex##group, pwcompare

See [R] margins for the available margins_options.

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

Suboptions

cieffects specifies that a table of the pairwise comparisons with their standard errors and confidence intervals be reported. This is the default.

pveffects specifies that a table of the pairwise comparisons with their standard errors, test statistics, and $p$-values be reported.

effects specifies that a table of the pairwise comparisons with their standard errors, test statistics, $p$-values, and confidence intervals be reported.

cimargins specifies that a table of the margins with their standard errors and confidence intervals be reported.

groups specifies that a table of the margins with their standard errors and group codes be reported. Margins with the same letter in the group code are not significantly different at the specified significance level.

sort specifies that the reported tables be sorted on the margins or contrasts in each term.
Remarks and examples

You should be familiar with the concepts and syntax of both \texttt{margins} and \texttt{pwcompare} before using the \texttt{pwcompare} option of \texttt{margins}. These remarks build on those in \cite{Stata2016a} \texttt{margins} and \cite{Stata2016} \texttt{pwcompare}.

\texttt{margins} can perform pairwise comparisons of any of the margins that it estimates.

We begin by fitting a logistic regression model using the NHANES II dataset, ignoring the complex survey nature of the data. Our dependent variable is \texttt{highbp}, an indicator for whether a person has high blood pressure. We fit an interacted model including two factor variables representing the region of the country as well as the continuous covariate \texttt{bmi}.

```
  . use http://www.stata-press.com/data/r14/nhanes2
  . logistic highbp region##c.bmi
     (output omitted)
```

By default, \texttt{margins} will compute the predictive margins of the probability of a positive outcome for each of the terms in \texttt{marginlist} after logistic regression. We will margin on \texttt{region} so that \texttt{margins} will estimate the average predicted probabilities of having high blood pressure conditional on being in each of the four regions and unconditional on BMI. We can specify the \texttt{pwcompare} option to obtain all possible pairwise comparisons of these predictive margins:

```
  . margins region, pwcompare
```

```
Pairwise comparisons of predictive margins
Model VCE : OIM
Expression : Pr(highbp), predict()
```

```
<table>
<thead>
<tr>
<th></th>
<th>Delta-method</th>
<th>Unadjusted</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Contrast</td>
<td>Std. Err.</td>
</tr>
<tr>
<td>region</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MW vs NE</td>
<td>-.0377194</td>
<td>.0133571</td>
</tr>
<tr>
<td>S vs NE</td>
<td>-.0156843</td>
<td>.0133986</td>
</tr>
<tr>
<td>W vs NE</td>
<td>-.006873</td>
<td>.0136595</td>
</tr>
<tr>
<td>S vs MW</td>
<td>.0220351</td>
<td>.0124564</td>
</tr>
<tr>
<td>W vs MW</td>
<td>.0308463</td>
<td>.0127366</td>
</tr>
<tr>
<td>W vs S</td>
<td>.0088112</td>
<td>.0127801</td>
</tr>
</tbody>
</table>
```

This table gives each of the pairwise differences with confidence intervals. We can see that the confidence interval in the row labeled \texttt{MW vs NE} does not include 0. At the 5\% level, the predictive margins for the first and second regions, the Northeast and the Midwest, are significantly different. The same is true of the second and fourth regions, the Midwest and the West. With many pairwise comparisons, output in this format can be difficult to sort through. We can organize it by adding the \texttt{group} suboption:
. margins region, pwcompare(group)
Pairwise comparisons of predictive margins
Model VCE : OIM
Expression : Pr(highbp), predict()

<table>
<thead>
<tr>
<th>region</th>
<th>Delta-method Unadjusted Margin</th>
<th>Std. Err.</th>
<th>Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>NE</td>
<td>.4388358</td>
<td>.010069</td>
<td>B</td>
</tr>
<tr>
<td>MW</td>
<td>.4011164</td>
<td>.0087764</td>
<td>A</td>
</tr>
<tr>
<td>S</td>
<td>.4231516</td>
<td>.0088395</td>
<td>AB</td>
</tr>
<tr>
<td>W</td>
<td>.4319628</td>
<td>.0092301</td>
<td>B</td>
</tr>
</tbody>
</table>

Note: Margins sharing a letter in the group label are not significantly different at the 5% level.

The group output includes the predictive margins for each region and letters denoting margins that are not significantly different from one another. In this case, the Northeast (NE), South (S), and West (W) regions have the letter B in the “Unadjusted Groups” column. The letter B indicates that the average predicted probability for the Northeast region is not significantly different from the average predicted probabilities for the South and West regions at the 5% significance level. The Midwest (MW) region does not share a letter with the Northeast region nor the West region, which indicates that the average predicted probability for the Midwest region is significantly different for each of the other two regions at our 5% level.

We can also include the mcompare(bonferroni) option to perform tests using Bonferroni’s method to account for making multiple comparisons.

. margins region, pwcompare(group) mcompare(bonferroni)
Pairwise comparisons of predictive margins
Model VCE : OIM
Expression : Pr(highbp), predict()

<table>
<thead>
<tr>
<th>region</th>
<th>Number of Comparisons</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>6</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>region</th>
<th>Delta-method Bonferroni Margin</th>
<th>Std. Err.</th>
<th>Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>NE</td>
<td>.4388358</td>
<td>.010069</td>
<td>B</td>
</tr>
<tr>
<td>MW</td>
<td>.4011164</td>
<td>.0087764</td>
<td>A</td>
</tr>
<tr>
<td>S</td>
<td>.4231516</td>
<td>.0088395</td>
<td>AB</td>
</tr>
<tr>
<td>W</td>
<td>.4319628</td>
<td>.0092301</td>
<td>AB</td>
</tr>
</tbody>
</table>

Note: Margins sharing a letter in the group label are not significantly different at the 5% level.

We now see the letter A on the row corresponding to the West region. At the 5% level and with Bonferroni’s adjustment, the predictive margins for the probability in the Midwest and West regions are not significantly different.
**Stored results**

`margins, pwcompare` stores the following additional results in `r()`:

 Scalars

- `r(k_terms)`
  number of terms participating in pairwise comparisons

 Macros

- `r(cmd)`
  pwcompare
- `r(cmd2)`
  margins
- `r(group#)`
  group code for the #th margin in `r(b)`
- `r(mcmethod_vs)`
  `method` from `mcompare()`
- `r(mctitle_vs)`
  title for `method` from `mcompare()`
- `r(mcadjustall_vs)`
  adjustall or empty

 Matrices

- `r(b)`
  margin estimates
- `r(V)`
  variance–covariance matrix of the margin estimates
- `r(b_vs)`
  margin difference estimates
- `r(V_vs)`
  variance–covariance margin difference of the margin estimates
- `r(error_vs)`
  margin difference estimability codes;
  0 means estimable,
  8 means not estimable
- `r(table_vs)`
  matrix containing the margin differences with their standard errors, test statistics,
  `p`-values, and confidence intervals
- `r(L)`
  matrix that produces the margin differences

`margins, pwcompare` with the `post` option also stores the following additional results in `e()`:

 Scalars

- `e(k_terms)`
  number of terms participating in pairwise comparisons

 Macros

- `e(cmd)`
  pwcompare
- `e(cmd2)`
  margins

 Matrices

- `e(b)`
  margin estimates
- `e(V)`
  variance–covariance matrix of the margin estimates
- `e(b_vs)`
  margin difference estimates
- `e(V_vs)`
  variance–covariance margin difference of the margin estimates
- `e(error_vs)`
  margin difference estimability codes;
  0 means estimable,
  8 means not estimable
- `e(L)`
  matrix that produces the margin differences

**Methods and formulas**

See *Methods and formulas* in [R] `margins` and *Methods and formulas* in [R] `pwcompare`.

Options

**xdimension(dimlist [, dimopts])** specifies the variables for the \(x\) axis in \(dimlist\) and controls the content of those labels with \(dimopts\).

**plotdimension(dimlist [, dimopts])** specifies in \(dimlist\) the variables whose group levels determine the plots and optionally specifies in \(dimopts\) the content of the plots’ labels.

**bydimension(dimlist [, dimopts])** specifies in \(dimlist\) the variables whose group levels determine the \(by()\) subgraphs and optionally specifies in \(dimopts\) the content of the subgraphs’ titles. For an example using \(by()\), see Three-way interactions.

**graphdimension(dimlist [, dimopts])** specifies in \(dimlist\) the variables whose group levels determine the graphs and optionally specifies in \(dimopts\) the content of the graphs’ titles.

**horizontal** reverses the default \(x\) and \(y\) axes. By default, the \(y\) axis represents the estimates of the margins and the \(x\) axis represents one or more factors or continuous covariates. Specifying **horizontal** swaps the axes so that the \(x\) axis represents the estimates of the margins. This option can be useful if the labels on the factor or continuous covariates are long.

The **horizontal** option is discussed in Horizontal is sometimes better.

**noci** removes plots of the pointwise confidence intervals. The default is to plot the confidence intervals.
name(name stub [, replace]) specifies the name of the graph or graphs. If the graphdimension() option is specified, or if the default action is to produce multiple graphs, then the argument of name() is taken to be stub and graphs named stub1, stub2, ... are created.

The replace suboption causes existing graphs with the specified name or names to be replaced. If name() is not specified, default names are used and the graphs may be replaced by subsequent marginsplot or other graphing commands.

With the exception of allxlabels, all of these options may be specified either directly as options or as dimopts within options xdimension(), plotdimension(), bydimension(), and graphdimension(). When specified in one of the dimension options, only the labels for that dimension are affected. When specified outside the dimension options, all labels on all dimensions are affected. Specifications within the dimension options take precedence.

allxlabels specifies that tick marks and labels be placed on the x axis for each value of the x-dimension variables. By default, if there are more than 25 ticks, default graph axis labeling rules are applied. Labeling may also be specified using the standard graph twoway x-axis label rules and options—xlabel(); see [G-3] axis_label_options.

nolabels specifies that value labels not be used to construct graph labels and titles for the group levels in the dimension. By default, if a variable in a dimension has value labels, those labels are used to construct labels and titles for axis ticks, plots, subgraphs, and graphs.

Graphs of contrasts and pairwise comparisons are an exception to this rule and are always labeled with values rather than value labels.

allsimplelabels and nosimplelabels control whether graphs’ labels and titles include just the values of the variables or include variable names and equal signs. The default is to use just the value label for variables that have value labels and to use variable names and equal signs for variables that do not have value labels. An example of the former is “Female” and the latter is “country=2”.

Sometimes value labels are universally descriptive, and sometimes they have meaning only when considered in relation to their variable. For example, “Male” and “Female” are typically universal, regardless of the variable from which they are taken. “High” and “Low” may not have meaning unless you know they are in relation to a specific measure, say, blood-pressure level. The allsimplelabels and nosimplelabels options let you override the default labeling.

allsimplelabels specifies that all titles and labels use just the value or value label of the variable.

nosimplelabels specifies that all titles and labels include varname= before the value or value label of the variable.

separator(string) and noseparator control the separator between label sections when more than one variable is used to specify a dimension. The default separator is a comma followed by a space, but no separator may be requested with noseparator or the default may be changed to any string with separator().

For example, if plotdimension(a b) is specified, the plot labels in our graph legend might be “a=1, b=1”, “a=1, b=2”, .... Specifying separator(:) would create labels “a=1:b=1”, “a=1:b=2”, ....
Plot

plotopts(plot_options) affects the rendition of all margin plots. The plot_options can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] marker_options, [G-3] marker_label_options, and [G-3] cline_options.

These settings may be overridden for specific plots by using the plot#opts() option.

plot#opts(plot_options) affects the rendition of the #th margin plot. The plot_options can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] marker_options, [G-3] marker_label_options, and [G-3] cline_options.

recast(plottype) specifies that margins be plotted using plottype. plottype may be scatter, line, connected, bar, area, spike, dropline, or dot; see [G-2] graph twoway. When recast() is specified, the plot-rendition options appropriate to the specified plottype may be used in lieu of plot_options. For details on those options, follow the appropriate link from [G-2] graph twoway.

For an example using recast(), see Continuous covariates.

You may specify recast() within a plotopts() or plot#opts() option. It is better, however, to specify it as documented here, outside those options. When specified outside those options, you have greater access to the plot-specific rendition options of your specified plottype.

CI plot

ciopts(rcap_options) affects the rendition of all confidence interval plots; see [G-3] rcap_options.

These settings may be overridden for specific confidence interval plots with the ci#opts() option.

ci#opts(rcap_options) affects the rendition of the #th confidence interval; see [G-3] rcap_options.

recastci(plottype) specifies that confidence intervals be plotted using plottype. plottype may be rarea, rbar, rspike, rcap, rcapsym, rline, rconnected, or rscatter; see [G-2] graph twoway. When recastci() is specified, the plot-rendition options appropriate to the specified plottype may be used in lieu of rcap_options. For details on those options, follow the appropriate link from [G-2] graph twoway.

For an example using recastci(), see Continuous covariates.

You may specify recastci() within a ciopts() or ci#opts() option. It is better, however, to specify it as documented here, outside those options. When specified outside those options, you have greater access to the plot-specific rendition options of your specified plottype.

mcompare(method) specifies the method for confidence intervals that account for multiple comparisons within a factor-variable term. The default is determined by the margins results stored in r(). If marginsplot is working from margins results stored in e(), the default is mcompare(noadjust).

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is determined by the margins results stored in r(). If marginsplot is working from margins results stored in e(), the default is level(95) or as set by set level; see [U] 20.7 Specifying the width of confidence intervals.

Pairwise

These options have an effect only when the pwcompare option was specified on the preceding margins command.

unique specifies that only unique pairwise comparisons be plotted. The default is to plot all pairwise comparisons, including those that are mirror images of each other—“male” versus “female” and “female” versus “male”. margins reports only the unique pairwise comparisons. unique
also changes the default `xdimension()` for graphs of pairwise comparisons from the reference categories (`-_pw0`) to the comparisons of each pairwise category (`-_pw`).

Unique comparisons are often preferred with horizontal graphs that put all pairwise comparisons on the `x` axis, whereas including the full matrix of comparisons is preferred for charts showing the reference groups on an axis and the comparison groups as plots; see Pairwise comparisons and Horizontal is sometimes better.

csort specifies that comparison categories are sorted first, and then reference categories are sorted within comparison category. The default is to sort reference categories first, and then sort comparison categories within reference categories. This option has an observable effect only when `-_pw` is also specified in one of the dimension options. It then determines the order of the labeling in the dimension where `-_pw` is specified.

```
addplot(plot) provides a way to add other plots to the generated graph; see [G-3] `addplot_option`
```
For an example using `addplot()`, see Adding scatterplots of the data.
If multiple graphs are drawn by a single `marginsplot` command or if `plot` specifies plots with multiple `y` variables, for example, `scatter y1 y2 x`, then the graph’s legend will not clearly identify all the plots and will require customization using the `legend()` option; see [G-3] `legend_option`

```
twoway_options are any of the options documented in [G-3] `twoway_options`. These include options for titling the graph (see [G-3] `title_options`); for saving the graph to disk (see [G-3] `saving_option`); for controlling the labeling and look of the axes (see [G-3] `axis_options`); for controlling the look, contents, position, and organization of the legend (see [G-3] `legend_options`); for adding lines (see [G-3] `added_line_options`) and text (see [G-3] `added_text_options`); and for controlling other aspects of the graph’s appearance (see [G-3] `twoway_options`).
```
The `label()` suboption of the `legend()` option has no effect on `marginsplot`. Use the `order()` suboption instead.

```
byopts(byopts) affects the appearance of the combined graph when `bydimension()` is specified or when the default graph has subgraphs, including the overall graph title, the position of the legend, and the organization of subgraphs. See [G-3] `by_option`.
```

- Horizontal is sometimes better
- Marginal effects
- Plotting a subset of the results from margins
- Advanced usage
  - Plots with multiple terms
  - Plots with multiple at() options
  - Adding scatterplots of the data
- Video examples

Introduction

`marginsplot` is a post-`margins` command. It graphs the results of the `margins` command, whether those results are marginal means, predictive margins, marginal effects, contrasts, pairwise comparisons, or other statistics; see [R] `margins`.

By default, the margins are plotted on the y axis, and all continuous and factor covariates specified in the `margins` command will usually be placed on the x axis or used to identify plots. Exceptions are discussed in the following sections and in Addendum: Advanced uses of dimlist below.

`marginsplot` produces classic plots, such as profile plots and interaction plots. Beyond that, anything that `margins` can compute, `marginsplot` can graph.

We will be using some relatively complicated `margins` commands with little explanation of the syntax. We will also avoid lengthy interpretations of the results of margins. See [R] `margins` for the complete syntax of `margins` and discussions of its results.

All graphs in this entry were drawn using the `s2gcolor` scheme; see [G-4] `scheme s2`.

Mitchell (2012) shows in many examples how to use `marginsplot` to understand a fitted model.

Dataset

For continuity, we will use one dataset for most examples—the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). NHANES II is part of a study to assess the health and nutritional status of adults and children in the United States. It is designed to be a nationally representative sample of the U.S. population. This particular sample is from 1976 to 1980.

The survey nature of the dataset—weights, strata, and sampling units—will be ignored in our analyses. We are discussing graphing, not survey statistics. If you would like to see the results with the appropriate adjustments for the survey design, just add `svy:` before each estimation command, and if you wish, add `vce(unconditional)` as an option to each `margins` command. See [R] `margins`, particularly the discussion and examples under Obtaining margins with survey data and representative
samples, for reasons why you probably would want to add \texttt{vce(unconditional)} when analyzing survey data. For the most part, adjusting for survey design produces moderately larger confidence intervals and relatively small changes in point estimates.

### Profile plots

What does my estimation say about how my response varies as one (or more) of my covariates changes? That is the question that is answered by profile plots. Profile plots are also referred to as plots of estimated (or expected, or least-squares) means, though that is unnecessarily restrictive when considering models of binary, count, and ordered outcomes. In the latter cases, we might prefer to say they plot conditional expectations of responses, where a response might be a probability.

What we do with the other covariates depends on the questions we wish to answer. Sometimes we wish to hold other covariates at fixed values, and sometimes we wish to average the response over their values. \texttt{margins} can do either, so you can graph either.

We can fit a fully factorial two-way ANOVA of systolic blood pressure on age group and sex using the NHANES II data.

```
. use http://www.stata-press.com/data/r14/nhanes2
. anova bpsystol agegrp##sex
```

If you are more comfortable with regression than ANOVA, then type

```
. regress bpsystol agegrp##sex
```

The \texttt{anova} and \texttt{regress} commands fit identical models. The output from \texttt{anova} displays all the terms in the model and thus tends to be more conducive to exploration with \texttt{margins} and \texttt{marginsplot}.

We estimate the predictive margins of systolic blood pressure for each age group using \texttt{margins}.

```
. margins agegrp
```

| agegrp  | Margin | Std. Err. | t     | P>|t| | [95% Conf. Interval] |
|---------|--------|-----------|-------|-----|----------------------|

The six predictive margins are just the averages of the predictions over the estimation sample, holding \texttt{agegrp} to each of its six levels. If this were a designed experiment rather than survey data, we might wish to assume the cells are balanced—that they have the same number of observations—and thus estimate what are often called expected means or least-squares means. To do that, we would simply add the \texttt{asbalanced} option to the \texttt{margins} command. The NHANES II data are decidedly unbalanced over \texttt{sex#agegrp} cells. So much so that it is unreasonable to assume the cells are balanced.

We graph the results:

```
. marginsplot
```

Variables that uniquely identify margins: \texttt{agegrp}

Profile plots are often drawn without confidence intervals (CIs). The CIs may be removed by adding the \texttt{noci} option. We prefer to see the CIs.

Disciplines vary widely in their use of the term profile plot. Some disciplines consider any connected plot of a response over values of other variables to be a profile plot. By that definition, most graphs in this entry are profile plots.

**Interaction plots**

Interaction plots are often used to explore the form of an interaction. The interaction term in our ANOVA results is highly significant. Are the interaction effects also large enough to matter? What form do they take? We can answer these questions by fixing \texttt{agegrp} and \texttt{sex} to each possible combination of the two covariates and estimating the margins for those cells.

```
. margins agegrp#sex
```
Then we can graph the results:

```
. marginsplot

Variables that uniquely identify margins: agegrp sex
```

It is clear that the effect of age differs by sex—there is an interaction. If there were no interaction, then the two lines would be parallel.

While males start out with higher systolic blood pressure, females catch up to the males as age increases and may even surpass males in the upper age groups. We say “may” because we cannot tell if the differences are statistically significant. The CIs overlap for the top three age groups. It is tempting to conclude from this overlap that the differences are not statistically significant. Do not fall into this trap. Likewise, do not fall into the trap that the first three age groups are different because their CIs do not overlap. The CIs are for the point estimates, not the differences. There is a covariance between the differences that we must consider if we are to make statements about those differences.

**Contrasts of margins—effects (discrete marginal effects)**

To assess the differences, all we need to do is ask `margins` to contrast the sets of effects that we just estimated; see `[R] margins, contrast`. With only two groups in sex, it does not matter much which contrast operator we choose. We will use the reference contrast. It will compare the difference between males and females, with males (the first category) as the reference category.

Because we are looking for effects that are different from 0, we will add a reference line at 0 to our graph.

. marginsplot, yline(0)
Variables that uniquely identify margins: agegrp

We can now say that females’ systolic blood pressure is substantially and significantly lower than males’ in the first three age groups but is significantly higher in the last two age groups. Despite the overlapping CIs for the last two age groups in the interaction graph, the effect of sex is significant in these age groups.
The terminology for what we just estimated and graphed varies widely across disciplines. Those versed in design of experiments refer to these values as contrasts or effects. Economists and some other social scientists call them marginal or partial effects. The latter groups might be more comfortable if we avoided the whole concept of contrasts and instead estimated the effects by typing

```
  . margins agegrp, dydx(sex)
```

This will produce estimates that are identical to those shown above, and we can graph them by typing `marginsplot`.

The advantage of using the contrast notation and thinking in contrasts is most evident when we take marginal effects with respect to a categorical covariate with more than two levels. Marginal effects for each level of the covariate will be taken with respect to a specified base level. Contrasts are much more flexible. Using the `r.` operator, we can reproduce the marginal-effects results by taking derivatives with respect to a reference level (as we saw above.) We can also estimate the marginal effect of first moving from level 1 to level 2, then from level 2 to level 3, then from level 3 to level 4, ... using the `ar.` or “reverse adjacent” operator. Adjacent effects (marginal effects) can be valuable when evaluating an ordinal covariate, such as `agegrp` in our current model. For a discussion of contrasts, see [R] `contrast` and [R] `margins, contrast`.

### Three-way interactions

`marginsplot` can handle any number of covariates in your `margins` command. Consider the three-way ANOVA model that results from adding an indicator for whether an individual has been diagnosed with diabetes. We will fully interact the new covariate with the others in the model.

```
  . anova bpsystol agegrp##sex##diabetes
```

</tbody>
</table>

The three-way interaction is significant, as is the main effect of `diabetes` and its interaction with `agegrp`.

Again, if you are more comfortable with regression than ANOVA, you may type

```
  . regress bpsystol agegrp##sex##diabetes
```

The `margins` and `marginsplot` results will be the same.
We estimate the expected cell means for each combination of `agegrp`, `sex`, and `diabetes`, and then graph the results by typing

```
margins agegrp#sex#diabetes
(output omitted)
marginsplot
```

Variables that uniquely identify margins: `agegrp` `sex` `diabetes`

The graph is busy and difficult to interpret.

We can make it better by putting those with diabetes on one subgraph and those without on another:

```
marginsplot, by(diabetes)
```

Variables that uniquely identify margins: `agegrp` `sex` `diabetes`

We notice much larger CIs for diabetics. That is not surprising because our sample contains only 499 diabetics compared with 9,850 nondiabetics.
A more interesting way to arrange the plots is by grouping the subgraphs on `sex`:

```
marginsplot, by(sex)
```

Variables that uniquely identify margins: `agegrp` `sex` `diabetes`

Aside from increased systolic blood pressure in the upper-age groups, which we saw earlier, it appears that those with diabetes are at greater risk of higher systolic blood pressure for many upper-age groups. We can check that by having `margins` estimate the differences between diabetics and nondiabetics, and graphing the results.

```
margins r.diabetes@agegrp#sex
(output omitted)
marginsplot, by(sex) yline(0)
```

Variables that uniquely identify margins: `agegrp` `sex`

With CIs above 0 for six of eight age groups over 40, this graph provides evidence that diabetes is related to higher blood pressure in those over 40.
Continuous covariates

`margins` and `marginsplot` are just as useful with continuous covariates as they are with factor variables. As a variation on our ANOVA/regression models, let’s move to a logistic regression, using as our dependent variable an indicator for whether a person has high blood pressure. We introduce a continuous covariate—body mass index (BMI), a measure of weight relative to height. High BMI is often associated with high blood pressure. We will allow the effect of BMI to vary across sexes, age groups, and sex/age combinations by fully interacting the covariates.

```
. logistic highbp sex##agegrp##c.bmi
```

If we wished, we could perform all the analyses above on this model. Instead of estimating margins, contrasts, and marginal effects on the level of systolic blood pressure, we would be estimating margins, contrasts, and marginal effects on the probability of having high blood pressure. You can see those results by repeating any of the prior commands that involve `sex` and `agegrp`. In this section, we will focus on the continuous covariate `bmi`.

With continuous covariates, rather than specify them in the `marginlist` of `margins`, we specify the specific values at which we want the covariate evaluated in an `at()` option. `at()` options are very flexible, and there are many ways to specify values; see `Syntax of at()` in [R] margins.

BMI in our sample ranges from 12.4 to 61.1. Let’s estimate the predictive margins for males and females at levels of BMI from 10 through 65 at intervals of 5 and graph the results:

```
. margins sex, at(bmi=(10(5)65))
(output omitted)
. marginsplot, xlabel(10(10)60)
```

We added the `xlabel(10(10)60)` option to improve the labeling of the $x$ axis. You may add any `twoway_options` (see [G-3] twoway_options) to the `marginsplot` command.

For a given BMI, males are generally more susceptible to high blood pressure, though the effect is attenuated by the logistic response when the probabilities approach 0 or 1.

Because `bmi` is continuous, we might prefer to see the response graphed using a line. We might also prefer that the CIs be plotted as areas. We change the plottype of the response by using the `recast()` option and the plottype of the CI by using the `recastci()` option:
The CI are a little dark for our tastes. You can dim them a bit by reducing the intensity of their color. Adding ciopts(color(*.8)) to our marginsplot command will do that. Any plot option accepted by twoway rarea (see [G-2] graph twoway rarea) may be specified in a ciopts() option.

Given their confidence regions, the male and female profiles appear to be statistically different over most of the range of BMI. As with the profiles of categorical covariates, we can check that assertion by contrasting the two profiles on sex and graphing the results. Let’s improve the smoothness of the response by specifying intervals of 1 instead of 5.

```
margins r.sex, at(bmi=(10(1)65))
(output omitted)
marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
```

We see that the difference between the sexes is largest at a BMI of about 35 and that the sexes respond more similarly with very high and very low BMI. This shape is largely determined by the
response of the logistic function, which is attenuated near probabilities 0 and 1, combined with the fact that the lowest measured BMIs are associated with low probabilities of high blood pressure and the highest measured BMIs are associated with high probabilities of high blood pressure.

As when we contrasted profiles of categorical variables, different disciplines will think of this graph differently. Those familiar with designed experiments will be comfortable with the terms used above—this is a contrast of profiles, or a profile of effects, or a profile of a contrast. Many social scientists will prefer to think of this as a graph of marginal or partial effects. For them, this is a plot of the discrete marginal effect of being female for various levels of BMI. They can obtain an identical graph, with labeling more appropriate for the marginal effect’s interpretation, by typing

```
   . margins, at(bmi=(10(1)65)) dydx(sex)
   . marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
```

We can also plot profiles of the response of BMI by levels of another continuous covariate (rather than by the categorical variable sex). To do so, we will need another continuous variable in our model. We have been using age groups as a covariate to emphasize the treatment of categorical variables and to allow the effect of age to be flexible. Our dataset also has age recorded in integer years. We replace `agegrp` with continuous `age` in our logistic regression.

```
   . logistic highbp sex##c.age##c.bmi
```

We can now obtain profiles of BMI for different ages by specifying ranges for both `bmi` and `age` in a single `at()` option on the `margins` command:

```
   . margins sex, at(bmi=(10(5)60) age=(20(10)70))
```

With six ages specified, we have many profiles, so we will dispense with the CIs by adding the `noci` option and also tidy up the graph by asking for three columns in the legend:

```
   . marginsplot, noci by(sex) legend(cols(3))
   Variables that uniquely identify margins: bmi age sex
```

Our model seems to indicate that males have a sharper reaction to body mass indices than do females. Likewise, younger subjects display a sharper response, while older subjects have a more gradual response with earlier onset. That interpretation might be a result of our parametric treatment of `age`. As it turns out, the interpretation holds if we allow age to take more flexible forms or return to our use of age groups, which allows each of seven age groups to have unique BMI profiles. Here are the commands to perform that analysis:
Plots at every value of a continuous covariate

In some cases, the specific values of a continuous covariate are important, and we want to plot the response at those specific values. Return to our logistic example with age treated as a continuous covariate.

```
. logistic highbp sex##c.age##c.bmi
(output omitted)
. margins sex#agegrp, at(age=('r(levels)'))
(output omitted)
. marginsplot, noci by(sex) legend(cols(3))
```

Variables that uniquely identify margins: bmi sex agegrp

See [P] levelsof for a discussion of the levelsof command. levelsof returns in `r(levels)` the sorted list of unique values of the specified varlist, in our case, age.

We can then plot the results using marginsplot.

This is not a very interesting trick when using our age variable, which is recorded as integers from 20 to 74, but the approach will work with almost any continuous variable. In our model, bmi might seem more interesting, but there are 9,941 unique values of bmi in our dataset. A graph cannot resolve so many different values. For that reason, we usually recommend against plotting at every value of a covariate. Instead, graph at reasonable values over the range of the covariate by using the at() option, as we did earlier. This trick is best reserved for variables with a few, or at most a few dozen, unique values.
Contrasts of at() groups—discrete effects

We have previously contrasted across the values of factor variables in our model. Put another way, we have estimated the discrete marginal effects of factor variables. We can do the same for the levels of variables in at() specifications and across separate at() specifications.

Returning to one of our logistic models and its margins of BMI at 5-unit intervals for both sexes. These are the commands we typed:

```
.logistic highbp sex##agegrp##c.bmi
.margins sex, at(bmi=(10(5)65))
marginsplot, xlabel(10(10)60)
```

We can estimate the discrete effects by sex of bmi moving from 10 to 15, then from 15 to 20, ..., and then from 60 to 65 by contrasting the levels of the at() groups using the reverse-adjacent contrast operator (ar.). We specify the operator within the atcontrast() suboption of the contrast() option. We need to specify one other option. By default, margins, contrast will apply a contrast to all variables in its marginlist when a contrast has been requested. In this case, we do not want to contrast across sexes but rather to contrast across the levels of BMI within each sex. To prevent margins from contrasting across the sexes, we specify the marginswithin option. Our margins command is

```
margins sex, at(bmi=(10(5)65)) contrast(atcontrast(ar._at) marginswithin)
```

And we graph the results using marginsplot:

```
marginsplot
Variables that uniquely identify margins: bmi sex
```

The graph shows the contrasts (or if you prefer, discrete changes) in the probability of high blood pressure by sex as one increases BMI in 5-unit increments.

We can even estimate contrasts (discrete effects) across at() options. To start, let’s compare the age-group profiles of the probability of high blood pressure for those in the 25th and 75th percentile of BMI.
For each age group, people whose BMI is at the 75th percentile have a much higher probability of high blood pressure than those at the 25th percentile. What is that difference in probability and its CI? To contrast across the percentiles of BMI within age groups, we again specify a contrast operator on the at() groups using atcontrast(), and we also tell margins to perform that contrast within the levels of the marginlist by using the marginswithin option.
The differences in probability between 25th and 75th BMI percentiles are clearly significantly greater than 0. The differences appear to be smallest for those in the youngest and oldest age groups.

**Controlling the graph’s dimensions**

Thus far, `marginsplot` has miraculously done almost exactly what we want in most cases. The things we want on the $x$ axis have been there, the choice of plots has made sense, etc. Some of that luck sprang from the relatively simple analyses we were performing, and some was from careful specification of our `margins` command. Sometimes, we will not be so lucky.
Consider the following `regress`, `margins`, and `marginsplot` commands:

```stata
. regress bpsystol agegrp##sex##c.bmi
(output omitted)
. margins agegrp, over(sex) at(bmi=(10(10)60))
(output omitted)
. marginsplot

Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
  _atoption=1: (p25) bmi
  _atoption=2: (p75) bmi
```

By default, `marginsplot` places the levels of the first multilevel `at()` specification on the \( x \) axis, and then usually plots the levels of all remaining variables as connected lines. That is what we see in the graph above—`bmi`, the `at()` variable, is on the \( x \) axis, and each combination of `agegrp` and `sex` is plotted as a separate connected line. If there is no multilevel `at()` specification, then the first variable in `marginlist` becomes the \( x \) axis. There are many more rules, but it is usually best to simply type `marginsplot` and see what happens. If you do not like `marginsplot`'s choices, change them.

What if we wanted `agegrp` on the \( x \) axis instead of `BMI`? We tell `marginsplot` to make that change by specifying `agegrp` in the `xdimension()` option:
. marginsplot, xdimension(agegrp)
Variables that uniquely identify margins: bmi agegrp sex

We have been suppressing the Results window output for `marginsplot`, but that output is helpful if we want to change how things are plotted. You may specify any variable used in your `margins` command in any of the dimension options—`xdimension()`, `plotdimension()`, `bydimension()`, and `graphdimension()` (In fact, there are some pseudovariables that you may also specify in some cases; see Addendum: Advanced uses of `dimlist` for details.) `marginsplot` tries to help you narrow your choices by listing a set of variables that uniquely identify all your margins. You are not restricted to this list.

We have a different x-axis and a different set of plots, but our graph is still busy and difficult to read. We can make it better by creating separate graph panels for each sex. We do that by adding a `bydimension()` option with `sex` as the argument.

. marginsplot, xdimension(agegrp) bydimension(sex)
Variables that uniquely identify margins: bmi agegrp sex

The patterns and the differences between males and females are now easier to see.

![Graph](image_url)
If our interest is in comparing males and females, we might even choose to create a separate panel for each level of BMI:

```stata
. marginsplot, xdimension(agegrp) bydimension(bmi) xlabel(, angle(45))
```

Variables that uniquely identify margins: bmi agegrp sex

![Predictive Margins of agegrp with 95% CIs](image)

The x-axis labels did not fit, so we angled them.

We leave you to explore the use of the `graphdimension()` option. It is much like `bydimension()` but creates separate graphs rather than separate panels. Operationally, the `plotdimension()` option is rarely used. All variables not in the x dimension and not specified elsewhere become the plotted connected lines.

You will likely use the dimension options frequently. This is one of the rare cases where we recommend using the minimal abbreviations of the options—`x()` for `xdimension()`, `plot()` for `plotdimension()`, `by()` for `bydimension()`, and `graph()` for `graphdimension()`. The abbreviations are easy to read and just as meaningful as the full option names. The full names exist to reinforce the relationship between the dimension options.

**Pairwise comparisons**

`marginsplot` can graph the results of `margins, pwcompare`; see [R] `margins, pwcompare`. We return to one of our ANOVA examples. Here we request pairwise comparisons with the `pwcompare` option of `margins`, and we request Bonferroni-adjusted CIs with the `mcompare()` option:
. anova bpsystol agegrp##sex
    (output omitted)
. margins agegrp, pwcompare mcompare(bonferroni)
    (output omitted)
. marginsplot

Variables that uniquely identify margins: _pw1 _pw0

    _pw enumerates all pairwise comparisons; _pw0 enumerates the reference
categories; _pw1 enumerates the comparison categories.

Each connected line plot in the graph represents a reference age-group category for the pairwise
comparison. The ticks on the $x$ axis represent comparison age-group categories. So, each plot is a
profile for a reference category showing its comparison to each other category.

**Horizontal is sometimes better**

Another interesting way to graph pairwise comparisons is to simply plot each comparison and
label the two categories being compared. This type of graph works better if it is oriented horizontally
rather than vertically.

Continuing with the example above, we will switch the graph to horizontal. We will also make
several changes to display the graph better. We specify that only unique comparisons be plotted. The
graph above plotted both 1 versus 2 and 2 versus 1, which are the same comparison with opposite
signs. We add a reference line at 0 because we are interested in comparisons that differ from 0. This
graph looks better without the connecting lines, so we add the option `recast(scatter)`. We also
reverse the $y$ scale so that the smallest levels of age group appear at the top of the axis.
All the comparisons differ from 0, so all our age groups are statistically different from each other.

The `horizontal` option can be useful outside of pairwise comparisons. Profile plots are usually oriented vertically. However, when your covariates have long labels or there are many levels at which the margins are being evaluated, the graph may be easier to read when rendered horizontally.

**Marginal effects**

We have seen how to graph discrete effects for factor variables and continuous variables by using contrasts, and optionally by using the `dydx()` option of `margins`: *Contrasts of margins—effects (discrete marginal effects)* and *Continuous covariates*. Let’s now consider graphing instantaneous marginal effects for continuous covariates. Begin by refitting our logistic model of high blood pressure as a function of sex, age, and BMI:

```
. logistic highbp sex##agegrp##c.bmi
```
We estimate the average marginal effect of BMI on the probability of high blood pressure for each age group and then graph the results by typing

```
.margins agegrp, dydx(bmi)
(output omitted)
.marginsplot
```

Variables that uniquely identify margins: agegrp

![Average Marginal Effects of bmi with 95% CIs](image)

These are the conditional expectations of the marginal effects treating everyone in the sample as though they were in each age group. We can estimate fully conditional marginal effects that do not depend on averaging over the sample by also margining on our one remaining covariate—sex.

```
.margins agegrp#sex, dydx(bmi)
(output omitted)
.marginsplot
```

Variables that uniquely identify margins: agegrp sex

![Average Marginal Effects of bmi with 95% CIs](image)

The effect of BMI on the probability of high blood pressure looks to increase with age for females. The marginal effect is higher for males than females in the younger age groups but then decreases with age for males after the 40–49 age group.
You may want to test for differences in the marginal effect of BMI for males and females by contrasting across sexes within `agegrp`:

```
    . margins r.sex@agegrp, dydx(bmi)
```

### Plotting a subset of the results from margins

`marginsplot` plots all the margins produced by the preceding `margins` command. If you want a graph that does not include all the margins, then enter a `margins` command that produces a reduced set of margins. Obvious ways to reduce the number of margins include not specifying some factors or interactions in the `marginlist` of `margins`, not specifying some `at()` or `over()` options, or reducing the values specified in an `at()` option. A less obvious technique uses selection lists in factor operators to select specific sets of levels from factor variables specified in the `marginlist`.

Instead of typing

```
    . margins agegrp
```
which will give you margins for all six age groups in our sample, type

```
    . margins i(2/4).agegrp
```
which will give you only three margins—those for groups 2, 3, and 4. See [U] 11.4.3.4 Selecting levels.

### Advanced usage

`margins` is incredibly flexible in the statistics it can estimate and in the grouping of those estimates. Many of the estimates that `margins` can produce do not make convincing graphs. `marginsplot` plots the results of any `margins` command, regardless of whether the resulting graph is easily interpreted. Here we demonstrate some options that can make complicated `margins` into graphs that are somewhat more useful than those produced by `marginsplot`’s defaults. Others may find truly useful applications for these approaches.

### Plots with multiple terms

Margins plots are rarely interesting when you specify multiple terms on your `margins` command, for example, `margins a b`. Such plots often compare things that are not comparable. The defaults for `marginsplot` rarely produce useful plots with multiple terms. Perhaps the most interesting graph in such cases puts all the levels of all the terms together on the vertical axis and plots their margins on the horizontal axis. We do that by including the `marginlist` from `margins` in an `xdimension()` option on `marginsplot`. The long labels on such graphs look better with a horizontal orientation, and there is no need to connect the margin estimates, so we specify the `recast(scatter)` option.
Using one of our ANOVA examples from earlier,

```
  . anova bpsystol agegrp##sex
  (output omitted)
  . margins agegrp sex
  (output omitted)
  . marginsplot, xdimension(agegrp sex) horizontal recast(scatter)
```

Variables that uniquely identify margins: agegrp sex

![](image)

The “asobserved” notations in the y-axis labels are informing us that, for example, when the margin for females is evaluated, the values of age group are taken as they are observed in the dataset. The margin is computed as an average over those values.

**Plots with multiple at() options**

Some disciplines like to compute margins at the means of other covariates in their model and others like to compute the response for each observation and then take the means of the response. These correspond to the `margins` options `at((mean) _all)` and `at((asobserved) _all)`. For responses that are linear functions of the coefficients, such as `predict` after `regress`, the two computations yield identical results. For responses that are nonlinear functions of the coefficients, the two computations estimate different things.

Using one of our logistic models of high blood pressure,

```
  . logistic highbp sex##agegrp##c.bmi
```

and computing both sets of margins for each age group,

```
  . margins agegrp, at((mean) _all) at((asobserved) _all)
```
we can use `marginsplot` to compare the approaches:

```
.marginsplot
  Variables that uniquely identify margins: agegrp _atopt
  Multiple at() options specified:
    _atoption=1: (mean) _all
    _atoption=2: (asobserved) _all
```

For the first three age groups, the probabilities of high blood pressure are lower at the means of `sex` and `bpi` than are the mean probabilities of high blood pressure averaged over the observed values of `sex` and `bpi`. The reverse is true for the last three age groups, although the values are very similar in these older age groups.
Such comparisons come up even more frequently when evaluating marginal effects. We can estimate the marginal effects of `sex` at each age group and graph the results by adding `dydx(sex)` to our `margins` command:

```
. margins agegrp, at((mean) _all) at((asobserved) _all) dydx(sex)
```

(output omitted)

```
. marginsplot
```

Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
  _atoption=1: (mean) _all
  _atoption=2: (asobserved) _all

The average marginal effect is smaller for most age groups, but the CIs for both sets of estimates are wide. Can we tell the difference between the estimates? To answer that, we use the now-familiar tactic of taking the contrast of our estimated marginal-effects profiles. That means adding `contrast(atjoint marginswithin)` to our `margins` command. We will also add `mcompare(bonferroni)` to account for the fact that we will be comparing six contrasts.

```
. margins agegrp, at((mean) _all) at((asobserved) _all) dydx(sex)
> contrast(atjoint marginswithin) mcompare(bonferroni)
```
We will also add the familiar reference line at 0 to our graph of the contrasts.

```
. marginsplot, yline(0)
```

Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
  _atoption=1: (mean)_all
  _atoption=2: (asobserved) _all

![Contrasts of Average Marginal Effects of 2.sex with 95% CIs](image)

While the difference in the estimates of marginal effects is not large, we can distinguish the estimates for the 30–39 and 70+ age groups.

The at() option of margins provides far more flexibility than demonstrated above. It can be used to evaluate a response or marginal effect at almost any point of interest or combinations of such points. See Syntax of at() in [R] margins.

Adding scatterplots of the data

We can add scatterplots of the observed data to our plots of the margins. The NHANES II dataset is too large for this to be interesting, so for this example, we will use auto.dta. We fit mileage on whether the care is foreign and on a quadratic in the weight of the car. We convert the weight into tons (U.S. definition) to improve the scaling, and we format the new tons variable to improve its labels on the graph. For our graph, we create separate variables for mileage of domestic and of foreign cars. We fit a fully interacted model so that the effect of weight on mileage can be different for foreign and for domestic cars.

```
. use http://www.stata-press.com/data/r14/auto
. generate tons = weight/2000
. format tons %6.2f
. separate mpg, by(foreign)
. regress mpg foreign##c.tons##c.tons
```

We then estimate the margins over the range of tons, using the option over(foreign) to obtain separate estimates for foreign and domestic cars.

```
. margins, at(tons=(.8(.05)2.4)) over(foreign)
```
Adding scatterplots of mileage for domestic and foreign cars is easy. We insert into an `addplot()` option of `marginsplot` the same scatterplot syntax for `twoway` that we would type to produce a scatterplot of the data:

```stata
. marginsplot, addplot(scatter mpg0 tons || scatter mpg1 tons) recast(line) noci
```

Variables that uniquely identify margins: `tons foreign`

Many will be surprised that the mileage profile is higher in 1978 for domestic (U.S. built) cars. Is the difference significant?

```stata
. margins, at(tons=(.8(.05)2.4)) over(r.for)
(output omitted)
. marginsplot, yline(0)
```

Variables that uniquely identify margins: `tons`

As we did earlier, we contrast the two profiles. We can discern some difference between the two profiles for midweight vehicles, but otherwise there is insufficient information to believe mileage differs across domestic and foreign cars.

Profile plots and interaction plots, part 5: Interactions of two continuous variables

Addendum: Advanced uses of dimlist

dimlist specifies the dimensions from the immediately preceding margins command that are to be used for the marginsplot’s x axis, plots, subgraphs, and graphs. dimlist may contain:

<table>
<thead>
<tr>
<th>dim</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>varname</td>
<td>Any variable referenced in the preceding margins command.</td>
</tr>
<tr>
<td>_equation</td>
<td>If the estimation command being analyzed is multivariate and margins automatically produced estimates for more than one dependent-variable equation, then dimlist may contain _equation to enumerate those equations.</td>
</tr>
<tr>
<td>_outcome</td>
<td>If the estimation command being analyzed is ordinal and margins automatically produced estimates for more than one outcome level, then dimlist may contain _outcome to enumerate those outcomes.</td>
</tr>
<tr>
<td>_predict</td>
<td>If the preceding margins command included multiple predict() options, then dimlist may contain _predict to enumerate those predict() options.</td>
</tr>
<tr>
<td>at(varname)</td>
<td>If a variable is specified in both the marginlist or the over() option and in the at() option of margins, then the two uses can be distinguished in marginsplot by typing the at() variables as at(varname) in dimlist.</td>
</tr>
<tr>
<td>_deriv</td>
<td>If the preceding margins command included a dydx(), eyex(), dyex(), or eydx() option, dimlist may also contain _deriv to specify all the variables over which derivatives were taken.</td>
</tr>
<tr>
<td>_term</td>
<td>If the preceding margins command included multiple terms (for example, margins a b), then dimlist may contain _term to enumerate those terms.</td>
</tr>
<tr>
<td>_atopt</td>
<td>If the preceding margins command included multiple at() options, then dimlist may contain _atopt to enumerate those at() options.</td>
</tr>
</tbody>
</table>

When the pairwise option is specified on margins, you may specify dimensions that enumerate the pairwise comparisons.

<table>
<thead>
<tr>
<th>dim</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_pw</td>
<td>enumerates all the pairwise comparisons</td>
</tr>
<tr>
<td>_pw0</td>
<td>enumerates the reference categories of the comparisons</td>
</tr>
<tr>
<td>_pw1</td>
<td>enumerates the comparison categories of the comparisons</td>
</tr>
</tbody>
</table>

Acknowledgments

We thank Philip B. Ender of UCLA Academic Technology Services for his programs that demonstrated what could be done in this area. We also thank Michael N. Mitchell, author of the Stata Press books Data Management Using Stata: A Practical Handbook, Interpreting and Visualizing Regression Models Using Stata, Stata for the Behavioral Sciences, and A Visual Guide to Stata Graphics, for his generous advice and comprehensive insight into the application of margins and their plots.

matsize — Set the maximum number of variables in a model

**Description**

set matsize sets the maximum matrix size, which influences the number of variables that can be included in any of Stata’s estimation commands. For Stata/MP, Stata/SE, and Stata/IC, the default value is 400, but it may be increased or decreased. This command may not be used with Small Stata; matsize is permanently frozen at 100.

Changing matsize has no effect on Mata.

**Syntax**

```stata
set matsize # [, permanently ]
```

where $10 \leq \# \leq 11000$ for Stata/MP and Stata/SE and where $10 \leq \# \leq 800$ for Stata/IC.

**Option**

permanently specifies that, in addition to making the change right now, the matsize setting be remembered and become the default setting when you invoke Stata.

**Remarks and examples**

set matsize controls the internal size of matrices that Stata uses. The default of 400 for Stata/IC, for instance, means that linear regression models are limited to 198 independent variables—198 because the constant uses one position and the dependent variable another, making a total of 200.

You may change matsize with data in memory, but increasing matsize increases the amount of memory consumed by Stata, increasing the probability of page faults and thus of making Stata run more slowly.

**Example 1**

We wish to fit a model of $y$ on the variables $x_1$ through $x_{400}$. Without thinking, we type

```stata
. regress y x1-x400
matsize too small
You have attempted to create a matrix with more than 400 rows or columns
or to fit a model with more than 400 variables plus ancillary parameters.
You need to increase matsize by using the set matsize command; see help matsize.
r(908);
```
We realize that we need to increase `matsize`, so we type

```
. set matsize 450
. regress y x1-x400
(output omitted)
```

Programmers should note that the current setting of `matsize` is stored as the c-class value `c(matsize)`; see [P] `creturn`.

All Stata commands maximize likelihood functions using moptimize() and optimize(); see Methods and formulas below. Commands use the Newton–Raphson method with step halving and special fixups when they encounter nonconcave regions of the likelihood. For details, see [M-5] moptimize() and [M-5] optimize(). For more information about programming maximum likelihood estimators in ado-files and Mata, see [R] ml and Gould, Pitblado, and Poi (2010).

set maxiter specifies the default maximum number of iterations for estimation commands that iterate. The initial value is 16000, and # can be 0 to 16000. To change the maximum number of iterations performed by a particular estimation command, you need not reset maxiter; you can specify the iterate(#) option. When iterate(#) is not specified, the maxiter value is used.

**Syntax**

*Maximum likelihood optimization*

```
mle_cmd ... [ , options ]
```

*Set default maximum iterations*

```
set maxiter # [, permanently ]
```

**Maximization options**

difficult specifies that the likelihood function is likely to be difficult to maximize because of nonconcave regions. When the message “not concave” appears repeatedly, ml’s standard stepping algorithm may not be working well. difficult specifies that a different stepping algorithm be used in nonconcave regions. There is no guarantee that difficult will work better than the default; sometimes it is better and sometimes it is worse. You should use the difficult option only when the default stepper declares convergence and the last iteration is “not concave” or when the default stepper is repeatedly issuing “not concave” messages and producing only tiny improvements in the log likelihood.

technique(algorithm_spec) specifies how the likelihood function is to be maximized. The following algorithms are allowed. For details, see Gould, Pitblado, and Poi (2010).

technique(nr) specifies Stata’s modified Newton–Raphson (NR) algorithm.
technique(bhhh) specifies the Berndt–Hall–Hall–Hausman (BHHH) algorithm.

technique(dfp) specifies the Davidon–Fletcher–Powell (DFP) algorithm.

technique(bfgs) specifies the Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm.

The default is technique(nr).

You can switch between algorithms by specifying more than one in the technique() option. By default, an algorithm is used for five iterations before switching to the next algorithm. To specify a different number of iterations, include the number after the technique in the option. For example, specifying technique(bhhh 10 nr 1000) requests that ml perform 10 iterations with the BHHH algorithm followed by 1000 iterations with the NR algorithm, and then switch back to BHHH for 10 iterations, and so on. The process continues until convergence or until the maximum number of iterations is reached.

iterate(#) specifies the maximum number of iterations. When the number of iterations equals iterate(), the optimizer stops and presents the current results. If convergence is declared before this threshold is reached, it will stop when convergence is declared. Specifying iterate(0) is useful for viewing results evaluated at the initial value of the coefficient vector. Specifying iterate(0) and from() together allows you to view results evaluated at a specified coefficient vector; however, not all commands allow the from() option. The default value of iterate(#) for both estimators programmed internally and estimators programmed with ml is the current value of set maxiter, which is iterate(16000) by default.

log and nolog specify whether an iteration log showing the progress of the log likelihood is to be displayed. For most commands, the log is displayed by default, and nolog suppresses it. For a few commands (such as the svy maximum likelihood estimators), you must specify log to see the log.

trace adds to the iteration log a display of the current parameter vector.

gradient adds to the iteration log a display of the current gradient vector.

showstep adds to the iteration log a report on the steps within an iteration. This option was added so that developers at StataCorp could view the stepping when they were improving the ml optimizer code. At this point, it mainly provides entertainment.

hessian adds to the iteration log a display of the current negative Hessian matrix.

showtolerance adds to the iteration log the calculated value that is compared with the effective convergence criterion at the end of each iteration. Until convergence is achieved, the smallest calculated value is reported.

shownrtolerance is a synonym of showtolerance.

Below we describe the three convergence tolerances. Convergence is declared when the nrtolerance() criterion is met and either the tolerance() or the ltolerance() criterion is also met.

tolerance(#) specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to tolerance(), the tolerance() convergence criterion is satisfied.

tolerance(1e-4) is the default for estimators programmed with ml.

tolerance(1e-6) is the default.
ltolerance(#) specifies the tolerance for the log likelihood. When the relative change in the log likelihood from one iteration to the next is less than or equal to ltolerance(), the ltolerance() convergence is satisfied.

ltolerance(0) is the default for estimators programmed with ml.

ltolerance(1e-7) is the default.

nrtolerance(#) specifies the tolerance for the scaled gradient. Convergence is declared when \( gH^{-1}g' < nrtolerance() \). The default is nrtolerance(1e-5).

qtolerance(#) when specified with algorithms bhhh, dfp, or bfgs uses the \( q-H \) matrix as the final check for convergence rather than nrtolerance() and the \( H \) matrix.

Beginning with Stata 12, by default, Stata now computes the \( H \) matrix when the \( q-H \) matrix passes the convergence tolerance, and Stata requires that \( H \) be concave and pass the nrtolerance() criterion before concluding convergence has occurred.

qtolerance() provides a way for the user to obtain Stata’s earlier behavior.

nonrtolerance specifies that the default nrtolerance() criterion be turned off.

from() specifies initial values for the coefficients. Not all estimators in Stata support this option. You can specify the initial values in one of three ways: by specifying the name of a vector containing the initial values (for example, from(b0), where b0 is a properly labeled vector); by specifying coefficient names with the values (for example, from(age=2.1 /sigma=7.4)); or by specifying a list of values (for example, from(2.1 7.4, copy)). from() is intended for use when doing bootstraps (see [R] bootstrap) and in other special situations (for example, with iterate(0)). Even when the values specified in from() are close to the values that maximize the likelihood, only a few iterations may be saved. Poor values in from() may lead to convergence problems.

skip specifies that any parameters found in the specified initialization vector that are not also found in the model be ignored. The default action is to issue an error message.

copy specifies that the list of values or the initialization vector be copied into the initial-value vector by position rather than by name.

Option for set maxiter

permanently specifies that, in addition to making the change right now, the maxiter setting be remembered and become the default setting when you invoke Stata.

Remarks and examples

Only in rare circumstances would you ever need to specify any of these options, except nolog. The nolog option is useful for reducing the amount of output appearing in log files.

The following is an example of an iteration log:

<table>
<thead>
<tr>
<th>Iteration</th>
<th>log likelihood</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-3791.0251</td>
</tr>
<tr>
<td>1</td>
<td>-3761.738</td>
</tr>
<tr>
<td>2</td>
<td>-3758.0632 (not concave)</td>
</tr>
<tr>
<td>3</td>
<td>-3758.0447</td>
</tr>
<tr>
<td>4</td>
<td>-3757.5861</td>
</tr>
<tr>
<td>5</td>
<td>-3757.474</td>
</tr>
<tr>
<td>6</td>
<td>-3757.4613</td>
</tr>
<tr>
<td>7</td>
<td>-3757.4606</td>
</tr>
<tr>
<td>8</td>
<td>-3757.4606</td>
</tr>
</tbody>
</table>

(table of results omitted)
At iteration 8, the model converged. The message “not concave” at the second iteration is notable. This example was produced using the `heckman` command; its likelihood is not globally concave, so it is not surprising that this message sometimes appears. The other message that is occasionally seen is “backed up”. Neither of these messages should be of any concern unless they appear at the final iteration.

If a “not concave” message appears at the last step, there are two possibilities. One is that the result is valid, but there is collinearity in the model that the command did not otherwise catch. Stata checks for obvious collinearity among the independent variables before performing the maximization, but strange collinearities or near collinearities can sometimes arise between coefficients and ancillary parameters. The second, more likely cause for a “not concave” message at the final step is that the optimizer entered a flat region of the likelihood and prematurely declared convergence.

If a “backed up” message appears at the last step, there are also two possibilities. One is that Stata found a perfect maximum and could not step to a better point; if this is the case, all is fine, but this is a highly unlikely occurrence. The second is that the optimizer worked itself into a bad concave spot where the computed gradient and Hessian gave a bad direction for stepping.

If either of these messages appears at the last step, perform the maximization again with the `gradient` option. If the gradient goes to zero, the optimizer has found a maximum that may not be unique but is a maximum. From the standpoint of maximum likelihood estimation, this is a valid result. If the gradient is not zero, it is not a valid result, and you should try tightening up the convergence criterion, or try `1tol(0) tol(1e-7)` to see if the optimizer can work its way out of the bad region.

If you get repeated “not concave” steps with little progress being made at each step, try specifying the `difficult` option. Sometimes `difficult` works wonderfully, reducing the number of iterations and producing convergence at a good (that is, concave) point. Other times, `difficult` works poorly, taking much longer to converge than the default stepper.

### Stored results

Maximum likelihood estimators store the following in `e()`:

**Scalars**

- `e(N)` number of observations always stored
- `e(k)` number of parameters always stored
- `e(k_eq)` number of equations in `e(b)` usually stored
- `e(k_eq_model)` number of equations in overall model test usually stored
- `e(k_dv)` number of dependent variables usually stored
- `e(df_m)` model degrees of freedom always stored
- `e(r2_p)` pseudo-$R$-squared sometimes stored
- `e(ll)` log likelihood always stored
- `e(ll_0)` log likelihood, constant-only model stored when constant-only model is fit
- `e(N_clust)` number of clusters stored when `vce(cluster clustvar)` is specified; see [U] 20.21 Obtaining robust variance estimates
- `e(chi2)` $\chi^2$ usually stored
- `e(p)` significance of model of test usually stored
- `e(rank)` rank of `e(V)` always stored
- `e(rank0)` rank of `e(V)` for constant-only model stored when constant-only model is fit
- `e(ic)` number of iterations usually stored
- `e(rc)` return code usually stored
- `e(converged)` 1 if converged, 0 otherwise usually stored
Macros

- `e(cmd)` name of command always stored
- `e(cmdline)` command as typed always stored
- `e(depvar)` names of dependent variables always stored
- `e(wtype)` weight type stored when weights are specified or implied
- `e(wexp)` weight expression stored when weights are specified or implied
- `e(title)` title in estimation output usually stored by commands using `ml`
- `e(clustvar)` name of cluster variable stored when `vce(cluster clustvar)` is specified; see [U] 20.21 Obtaining robust variance estimates
- `e(chi2type)` Wald or LR; type of model \(\chi^2\) test usually stored
- `e(vcetype)` `vcetype` specified in `vce()` stored when command allows (`vce()`)
- `e(properties)` estimator properties always stored
- `e(predict)` program used to implement `predict` usually stored

Matrices

- `e(b)` coefficient vector always stored
- `e(Cns)` constraints matrix sometimes stored
- `e(ilog)` iteration log (up to 20 iterations) usually stored
- `e(gradient)` gradient vector usually stored
- `e(V)` variance–covariance matrix of the estimators always stored
- `e(V_modelbased)` model-based variance only stored when `e(V)` is neither the OIM nor OPG variance

Functions

- `e(sample)` marks estimation sample always stored

1. Type `ereturn list, all` to view these results; see [P] return.

See Stored results in the manual entry for any maximum likelihood estimator for a list of returned results.

Methods and formulas

Optimization is currently performed by `moptimize()` and `optimize()`, with the former implemented in terms of the latter; see [M-5] `moptimize()` and [M-5] `optimize()`. Some estimators use `moptimize()` and `optimize()` directly, and others use the `ml` ado-file interface to `moptimize()`.

Prior to Stata 11, Stata had three separate optimization engines: an internal one used by estimation commands implemented in C code; `ml` implemented in ado-code separately from `moptimize()` and used by most estimators; and `moptimize()` and `optimize()` used by a few recently written
estimators. These days, the internal optimizer and the old version of `ml` are used only under version control. In addition, `arch` and `arima` (see `TS arch` and `TS arima`) are currently implemented using the old `ml`.

Let $L_1$ be the log likelihood of the full model (that is, the log-likelihood value shown on the output), and let $L_0$ be the log likelihood of the “constant-only” model. The likelihood-ratio $\chi^2$ model test is defined as $2(L_1 - L_0)$. The pseudo-$R^2$ (McFadden 1974) is defined as $1 - L_1/L_0$. This is simply the log likelihood on a scale where 0 corresponds to the “constant-only” model and 1 corresponds to perfect prediction for a discrete model (in which case the overall log likelihood is 0).

Some maximum likelihood routines can report coefficients in an exponentiated form, for example, odds ratios in `logistic`. Let $b$ be the unexponentiated coefficient, $s$ its standard error, and $b_0$ and $b_1$ the reported confidence interval for $b$. In exponentiated form, the point estimate is $e^b$, the standard error $e^b s$, and the confidence interval $e^{b_0}$ and $e^{b_1}$. The displayed $Z$ (or $t$) statistics and $p$-values are the same as those for the unexponentiated results. This is justified because $e^b = 1$ and $b = 0$ are equivalent hypotheses, and normality is more likely to hold in the $b$ metric.

**Description**

`mean` produces estimates of means, along with standard errors.

**Quick start**

Mean, standard error, and 95% confidence interval for `v1`

```
mean v1
```

Also compute statistics for `v2`

```
mean v1 v2
```

As above, but for each level of categorical variable `catvar1`

```
mean v1 v2, over(catvar1)
```

Weighting by probability weight `wvar`

```
mean v1 v2 [pweight=wvar]
```

Population mean using `svyset` data

```
svy: mean v3
```

As above, but for each level of categorical variable `catvar2`

```
svy: mean v3, over(catvar2)
```

Two-group `t` test with `svyset` data if levels of `catvar2` are labeled `c1` and `c2`

```
svy: mean v3, over(catvar2)
test c1 = c2
```

**Menu**

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Means
mean varlist [if] [in] [weight] [ , options ]

Model

stdize(varname) variable identifying strata for standardization
stdweight(varname) weight variable for standardization
nostdrescale do not rescale the standard weight variable

if/in/over

over(varlist[, nolabel]) group over subpopulations defined by varlist; optionally, suppress group labels

SE/Cluster

vce(vcetype) vcetype may be analytic, cluster clustvar, bootstrap, or jackknife

Reporting

level(#) set confidence level; default is level(95)
nohheader suppress table header
nolegend suppress table legend
display_options control column formats and line width
coeflegend display legend instead of statistics

Options

stdize(varname) specifies that the point estimates be adjusted by direct standardization across the strata identified by varname. This option requires the stdweight() option.

stdweight(varname) specifies the weight variable associated with the standard strata identified in the stdize() option. The standardization weights must be constant within the standard strata.
nostdrescale prevents the standardization weights from being rescaled within the over() groups. This option requires stdize() but is ignored if the over() option is not specified.

over(varlist[, nolabel]) specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in varlist.
When this option is supplied with one variable name, such as `over(varname)`, the value labels of `varname` are used to identify the subpopulations. If `varname` does not have labeled values (or there are unlabeled values), the values themselves are used, provided that they are nonnegative integers. Noninteger values, negative values, and labels that are not valid Stata names are substituted with a default identifier.

When `over()` is supplied with multiple variable names, each subpopulation is assigned a unique default identifier.

`nolabel` requests that value labels attached to the variables identifying the subpopulations be ignored.

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (analytic), that allow for intragroup correlation (cluster `clustvar`), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] `vce_option`.

`vce(analytic)`, the default, uses the analytically derived variance estimator associated with the sample mean.

`level(#);` see [R] `estimation options`.

`noheader` prevents the table header from being displayed. This option implies `nolegend`. `nolegend` prevents the table legend identifying the subpopulations from being displayed.

`display_options: cformat(%,fmt) and nolstretch;` see [R] `estimation options`.

The following option is available with `mean` but is not shown in the dialog box: `coeflegend`; see [R] `estimation options`. 
Remarks and examples

Example 1

Using the fuel data from example 3 of [R] ttest, we estimate the average mileage of the cars without the fuel treatment (\texttt{mpg1}) and those with the fuel treatment (\texttt{mpg2}).

\begin{verbatim}
. use http://www.stata-press.com/data/r14/fuel
. mean mpg1 mpg2
  
Mean estimation Number of obs = 12

<table>
<thead>
<tr>
<th></th>
<th>Mean</th>
<th>Std. Err.</th>
<th>[95% Conf. Interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg1</td>
<td>21.00</td>
<td>0.7881701</td>
<td>19.26525  22.73475</td>
</tr>
<tr>
<td>mpg2</td>
<td>22.75</td>
<td>0.9384465</td>
<td>20.68449  24.81551</td>
</tr>
</tbody>
</table>
\end{verbatim}

Using these results, we can test the equality of the mileage between the two groups of cars.

\begin{verbatim}
. test mpg1 = mpg2
( 1) mpg1 - mpg2 = 0

F( 1, 11) = 5.04
Prob > F = 0.0463
\end{verbatim}

Example 2

In example 1, the joint observations of \texttt{mpg1} and \texttt{mpg2} were used to estimate a covariance between their means.

\begin{verbatim}
. matrix list e(V)
  
symmetric e(V)[2,2]
     mpg1     mpg2
mpg1  0.62121212  
mpg2  0.4469697  0.88068182
\end{verbatim}

If the data were organized this way out of convenience but the two variables represent independent samples of cars (coincidentally of the same sample size), we should reshape the data and use the \texttt{over()} option to ensure that the covariance between the means is zero.

\begin{verbatim}
. use http://www.stata-press.com/data/r14/fuel
. stack mpg1 mpg2, into(mpg) clear
. mean mpg, over(_stack)
  
Mean estimation Number of obs = 24
  
1: _stack = 1
2: _stack = 2

<table>
<thead>
<tr>
<th></th>
<th>Mean</th>
<th>Std. Err.</th>
<th>[95% Conf. Interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>21.00</td>
<td>0.7881701</td>
<td>19.36955  22.63045</td>
</tr>
<tr>
<td></td>
<td>22.75</td>
<td>0.9384465</td>
<td>20.80868  24.69132</td>
</tr>
</tbody>
</table>
\end{verbatim}
mean — Estimate means

Now we can test the equality of the mileage between the two independent groups of cars.

    . test [mpg]1 = [mpg]2
     ( 1) [mpg]1 - [mpg]2 = 0
      F( 1, 23) = 2.04
      Prob > F = 0.1667

Example 3: standardized means

Suppose that we collected the blood pressure data from example 2 of [R] dstdize, and we wish to obtain standardized high blood pressure rates for each city in 1990 and 1992, using, as the standard, the age, sex, and race distribution of the four cities and two years combined. Our rate is really the mean of a variable that indicates whether a sampled individual has high blood pressure. First, we generate the strata and weight variables from our standard distribution, and then use mean to compute the rates.

    . use http://www.stata-press.com/data/r14/hbp, clear
    . egen strata = group(age race sex) if inlist(year, 1990, 1992)
    (675 missing values generated)
    . by strata, sort: gen stdw = _N
    . mean hbp, over(city year) stdize(strata) stdweight(stdw)

Mean estimation
N. of std strata = 24 Number of obs = 455
Over: city year
  _subpop_1: 1 1990
  _subpop_2: 1 1992
  _subpop_3: 2 1990
  _subpop_4: 2 1992
  _subpop_5: 3 1990
  _subpop_6: 3 1992
  _subpop_7: 5 1990
  _subpop_8: 5 1992

<table>
<thead>
<tr>
<th>Over</th>
<th>Mean</th>
<th>Std. Err.</th>
<th>[95% Conf. Interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>hbp</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>_subpop_1</td>
<td>.058642</td>
<td>.0296273</td>
<td>.0004182 .1168657</td>
</tr>
<tr>
<td>_subpop_2</td>
<td>.0117647</td>
<td>.0113187</td>
<td>-.0104789 .0340083</td>
</tr>
<tr>
<td>_subpop_3</td>
<td>.0488722</td>
<td>.0238958</td>
<td>.0019121 .0958322</td>
</tr>
<tr>
<td>_subpop_4</td>

<tr>
<td>_subpop_7</td>
<td>.0277778</td>
<td>.0155121</td>
<td>-.0027066 .0582622</td>
</tr>
<tr>
<td>_subpop_8</td>
<td>.0548926</td>
<td>0</td>
<td>.</td>
</tr>
</tbody>
</table>

The standard error of the high blood pressure rate estimate is missing for city 5 in 1992 because there was only one individual with high blood pressure; that individual was the only person observed in the stratum of white males 30–35 years old.
By default, `mean` rescales the standard weights within the `over()` groups. In the following, we use the `nostdrescale` option to prevent this, thus reproducing the results in [R] `dstdize`.

```
mean hbp, over(city year) nolegend stdize(strata) stdweight(stdw) 
> nostdrescale
```

Mean estimation

```
N. of std strata = 24 Number of obs = 455
```

```

Video example

Descriptive statistics in Stata

Stored results

`mean` stores the following in `e()`:

Scalars
- `e(N)` number of observations
- `e(N_over)` number of subpopulations
- `e(N_stdize)` number of standard strata
- `e(N_clust)` number of clusters
- `e(k_eq)` number of equations in `e(b)`
- `e(df_r)` sample degrees of freedom
- `e(rank)` rank of `e(V)`

Macros
- `e(cmd)` `mean`
- `e(cmdline)` command as typed
- `e(varlist)` `varlist`
- `e(stdize)` `varname` from `stdize()`
- `e(stdweight)` `varname` from `stdweight()`
- `e(vtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(cluster)` name of cluster variable
- `e(over)` `varlist` from `over()`
- `e(over_labels)` labels from `over()` variables
- `e(over_namelist)` names from `e(over_labels)`
- `e(vce)` `vcetype` specified in `vce()`
- `e(vcetype)` title used to label Std. Err.
- `e(properties)` `b V`
- `e(estat_cmd)` program used to implement `estat`
- `e(marginsnotok)` predictions disallowed by `margins`
Matrices
\[ e(b) \] vector of mean estimates
\[ e(V) \] (co)variance estimates
\[ e(N) \] vector of numbers of nonmissing observations
\[ e(_N\_stdsum) \] number of nonmissing observations within the standard strata
\[ e(_p\_stdize) \] standardizing proportions
\[ e(error) \] error code corresponding to \[ e(b) \]

Functions
\[ e(sample) \] marks estimation sample

Methods and formulas

Methods and formulas are presented under the following headings:

* The mean estimator
* Survey data
* The survey mean estimator
* The standardized mean estimator
* The poststratified mean estimator
* The standardized poststratified mean estimator
* Subpopulation estimation

The mean estimator

Let \( y \) be the variable on which we want to calculate the mean and \( y_j \) an individual observation on \( y \), where \( j = 1, \ldots, n \) and \( n \) is the sample size. Let \( w_j \) be the weight, and if no weight is specified, define \( w_j = 1 \) for all \( j \). For \texttt{aweights}, the \( w_j \) are normalized to sum to \( n \). See The survey mean estimator for \texttt{pweight} ed data.

Let \( W \) be the sum of the weights

\[
W = \sum_{j=1}^{n} w_j
\]

The mean is defined as

\[
\bar{y} = \frac{1}{W} \sum_{j=1}^{n} w_j y_j
\]

The default variance estimator for the mean is

\[
\hat{V}(\bar{y}) = \frac{1}{W(W-1)} \sum_{j=1}^{n} w_j (y_j - \bar{y})^2
\]

The standard error of the mean is the square root of the variance.

If \( x, x_j, \) and \( \bar{x} \) are similarly defined for another variable (observed jointly with \( y \)), the covariance estimator between \( \bar{x} \) and \( \bar{y} \) is

\[
\hat{\text{Cov}}(\bar{x}, \bar{y}) = \frac{1}{W(W-1)} \sum_{j=1}^{n} w_j (x_j - \bar{x})(y_j - \bar{y})
\]
Survey data

See [SVY] variance estimation, [SVY] direct standardization, and [SVY] poststratification for discussions that provide background information for the following formulas. The following formulas are derived from the fact that the mean is a special case of the ratio estimator where the denominator variable is one, \( x_j = 1 \); see [R] ratio.

The survey mean estimator

Let \( Y_j \) be a survey item for the \( j \)th individual in the population, where \( j = 1, \ldots, M \) and \( M \) is the size of the population. The associated population mean for the item of interest is \( \bar{Y} = Y/M \) where

\[
Y = \sum_{j=1}^{M} Y_j
\]

Let \( y_j \) be the survey item for the \( j \)th sampled individual from the population, where \( j = 1, \ldots, m \) and \( m \) is the number of observations in the sample.

The estimator for the mean is \( \bar{y} = \hat{Y}/\hat{M} \), where

\[
\hat{Y} = \sum_{j=1}^{m} w_j y_j \quad \text{and} \quad \hat{M} = \sum_{j=1}^{m} w_j 
\]

and \( w_j \) is a sampling weight. The score variable for the mean estimator is

\[
z_j(\bar{y}) = \frac{y_j - \bar{y}}{\hat{M}} = \frac{\hat{M} y_j - \hat{Y}}{\hat{M}^2}
\]

The standardized mean estimator

Let \( D_g \) denote the set of sampled observations that belong to the \( g \)th standard stratum and define \( I_{D_g}(j) \) to indicate if the \( j \)th observation is a member of the \( g \)th standard stratum; where \( g = 1, \ldots, L_D \) and \( L_D \) is the number of standard strata. Also, let \( \pi_g \) denote the fraction of the population that belongs to the \( g \)th standard stratum, thus \( \pi_1 + \cdots + \pi_{L_D} = 1 \). \( \pi_g \) is derived from the stdweight() option.

The estimator for the standardized mean is

\[
\bar{y}^D = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g}{\hat{M}_g}
\]

where

\[
\hat{Y}_g = \sum_{j=1}^{m} I_{D_g}(j) w_j y_j \quad \text{and} \quad \hat{M}_g = \sum_{j=1}^{m} I_{D_g}(j) w_j
\]

The score variable for the standardized mean is

\[
z_j(\bar{y}^D) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) \frac{\hat{M}_g y_j - \hat{Y}_g}{\hat{M}_g^2}
\]
The poststratified mean estimator

Let $P_k$ denote the set of sampled observations that belong to poststratum $k$ and define $I_{P_k}(j)$ to indicate if the $j$th observation is a member of poststratum $k$; where $k = 1, \ldots, L_P$ and $L_P$ is the number of poststrata. Also let $M_k$ denote the population size for poststratum $k$. $P_k$ and $M_k$ are identified by specifying the `poststrata()` and `postweight()` options on `svyset`; see [SVY] svyset.

The estimator for the poststratified mean is

$$
\bar{y}^P = \frac{\hat{Y}^P}{\hat{M}^P} = \frac{\hat{Y}^P}{M}
$$

where

$$
\hat{Y}^P = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \hat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \sum_{j=1}^{m} I_{P_k}(j) w_j y_j
$$

and

$$
\hat{M}^P = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \hat{M}_k = \sum_{k=1}^{L_P} M_k = M
$$

The score variable for the poststratified mean is

$$
z_j(\bar{y}^P) = \frac{z_j(\hat{Y}^P)}{M} = \frac{1}{M} \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\hat{M}_k} \left( y_j - \frac{\hat{Y}_k}{\hat{M}_k} \right)
$$

The standardized poststratified mean estimator

The estimator for the standardized poststratified mean is

$$
\bar{y}^{DP} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}^P_g}{\hat{M}^P_g}
$$

where

$$
\hat{Y}^P_g = \sum_{k=1}^{L_p} \frac{M_k}{\hat{M}_k} \hat{Y}_{g,k} = \sum_{k=1}^{L_p} \frac{M_k}{\hat{M}_k} \sum_{j=1}^{m} I_{D_g}(j) I_{P_k}(j) w_j y_j
$$

and

$$
\hat{M}^P_g = \sum_{k=1}^{L_p} \frac{M_k}{\hat{M}_k} \hat{M}_{g,k} = \sum_{k=1}^{L_p} \frac{M_k}{\hat{M}_k} \sum_{j=1}^{m} I_{D_g}(j) I_{P_k}(j) w_j
$$

The score variable for the standardized poststratified mean is

$$
z_j(\bar{y}^{DP}) = \sum_{g=1}^{L_D} \pi_g \frac{\hat{M}^P_g z_j(\hat{Y}^P_g) - \hat{Y}^P_g z_j(\hat{M}^P)}{\left(\hat{M}^P_g\right)^2}
$$

where

$$
z_j(\hat{Y}^P_g) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\hat{M}_k} \left( I_{D_g}(j) y_j - \frac{\hat{Y}_{g,k}}{\hat{M}_k} \right)
$$

and

$$
z_j(\hat{M}^P_g) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\hat{M}_k} \left( I_{D_g}(j) - \frac{\hat{M}_{g,k}}{\hat{M}_k} \right)
$$
Subpopulation estimation

Let $S$ denote the set of sampled observations that belong to the subpopulation of interest, and define $I_S(j)$ to indicate if the $j$th observation falls within the subpopulation.

The estimator for the subpopulation mean is $\hat{Y}^S = \hat{Y}^S / \hat{M}^S$, where

$$\hat{Y}^S = \sum_{j=1}^{m} I_S(j) w_j y_j \quad \text{and} \quad \hat{M}^S = \sum_{j=1}^{m} I_S(j) w_j$$

Its score variable is

$$z_j(\hat{Y}^S) = I_S(j) \frac{y_j - \hat{Y}^S}{\hat{M}^S} = I_S(j) \frac{\hat{M}^S y_j - \hat{Y}^S}{(\hat{M}^S)^2}$$

The estimator for the standardized subpopulation mean is

$$\bar{Y}^{DS} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}^S_g}{\hat{M}^S_g}$$

where

$$\hat{Y}^S_g = \sum_{j=1}^{m} I_{D_g}(j) I_S(j) w_j y_j \quad \text{and} \quad \hat{M}^S_g = \sum_{j=1}^{m} I_{D_g}(j) I_S(j) w_j$$

Its score variable is

$$z_j(\bar{Y}^{DS}) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) I_S(j) \frac{\hat{M}^S_g y_j - \hat{Y}^S_g}{(\hat{M}^S_g)^2}$$

The estimator for the poststratified subpopulation mean is

$$\bar{Y}^{PS} = \frac{\hat{Y}^{PS}}{\hat{M}^{PS}}$$

where

$$\hat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{M} \hat{Y}^S_k = \sum_{k=1}^{L_P} \frac{M_k}{M} \sum_{j=1}^{m} I_{P_k}(j) I_S(j) w_j y_j$$

and

$$\hat{M}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{M} \hat{M}^S_k = \sum_{k=1}^{L_P} \frac{M_k}{M} \sum_{j=1}^{m} I_{P_k}(j) I_S(j) w_j$$

Its score variable is

$$z_j(\bar{Y}^{PS}) = \frac{\hat{M}^{PS} z_j(\hat{Y}^{PS}) - \hat{Y}^{PS} z_j(\hat{M}^{PS})}{(\hat{M}^{PS})^2}$$

where

$$z_j(\hat{Y}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{M_k} \left\{ I_S(j) y_j - \frac{\hat{Y}^S_k}{M_k} \right\}$$
and

\[ z_j(\hat{M}^{PS}) = \sum_{k=1}^{L_P} IP_k(j) \frac{M_k}{M} \left\{ I_S(j) - \frac{\hat{M}_k^S}{M_k} \right\} \]

The estimator for the standardized poststratified subpopulation mean is

\[ \bar{y}^{DPS} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}^{PS}_g}{M_g} \]

where

\[ \hat{Y}^{PS}_g = \sum_{k=1}^{L_p} M_k \hat{Y}^{S}_{g,k} = \sum_{k=1}^{L_p} M_k \sum_{j=1}^{m} ID_g(j) IP_k(j) I_S(j) w_j y_j \]

and

\[ \hat{M}^{PS}_g = \sum_{k=1}^{L_p} M_k \hat{M}^{S}_{g,k} = \sum_{k=1}^{L_p} M_k \sum_{j=1}^{m} ID_g(j) IP_k(j) I_S(j) w_j \]

Its score variable is

\[ z_j(\bar{y}^{DPS}) = \sum_{g=1}^{L_D} \pi_g \frac{\hat{M}^{PS}_g z_j(\hat{Y}^{PS}_g) - \hat{Y}^{PS}_g z_j(\hat{M}^{PS}_g)}{(\hat{M}^{PS}_g)^2} \]

where

\[ z_j(\hat{Y}^{PS}_g) = \sum_{k=1}^{L_p} IP_k(j) \frac{M_k}{M} \left\{ I_D_g(j) I_S(j) y_j - \frac{\hat{Y}^{S}_{g,k}}{M_k} \right\} \]

and

\[ z_j(\hat{M}^{PS}_g) = \sum_{k=1}^{L_p} IP_k(j) \frac{M_k}{M} \left\{ I_D_g(j) I_S(j) - \frac{\hat{M}^{S}_{g,k}}{M_k} \right\} \]

</tbody>
</table>

Remarks and examples

For an example of testing for a difference in weighted means using `lincom` after `mean`, see Pollock (2015, 106–107).

Example 1

We have a dataset with monthly rates of returns on the Dow and NASDAQ stock indices. We can use `mean` to compute the average quarterly rates of return for the two indices separately:

```
. use http://www.stata-press.com/data/r14/rates
. mean dow nasdaq
```

If you chose just one of the indices for your portfolio, you either did rather well or rather poorly, depending on which one you picked. However, as we now show with the postestimation command `lincom`, if you diversified your portfolio, you would have earned a respectable 5.5% rate of return without having to guess which index would be the better performer.
. lincom .5*dow + .5*nasdaq
( 1) .5*dow + .5*nasdaq = 0

[U] 20 Estimation and postestimation commands
Remarks and examples

Stata does not have a meta-analysis command. Stata users, however, have developed an excellent suite of commands for performing meta-analysis, including commands for performing standard and cumulative meta-analysis, commands for producing forest plots and contour-enhanced funnel plots, and commands for nonparametric analysis of publication bias.

Many articles describing these commands have been published in the *Stata Technical Bulletin* and the *Stata Journal*. These articles were updated and published in a cohesive collection: *Meta-Analysis in Stata: An Updated Collection from the Stata Journal*.

In this collection, editors Tom Palmer and Jonathan Sterne discuss how these articles relate to each other and how they fit in the overall literature of meta-analysis. Palmer and Sterne have organized the collection into seven areas: classic meta-analysis; meta-regression; graphical and analytic tools for detecting bias; multivariate meta-analysis; individual patient data meta-analysis; network meta-analysis; and recent advances such as meta-analysis for dose–response curves, diagnostic accuracy, and studies containing missing values.

We highly recommend that Stata users interested in meta-analysis read this book.

Please also see the following FAQ on the Stata website:

What meta-analysis features are available in Stata?
http://www.stata.com/support/faqs/stat/meta.html

References

**Description**

`mfp` selects the multivariable fractional polynomial (MFP) model that best predicts the outcome variable from the right-hand-side variables in `xvarlist`.

For univariate fractional polynomials, `fp` can be used to fit a wider range of models than `mfp`. See `[R] fp` for more details.

**Quick start**

Find optimal MFP model for regression of `y` on fractional polynomials of `x1`, `x2`, and `x3`  
```
mfp: regress y x1 x2 x3
```
As above, but search only powers of $-1$, $-0.5$, $1$, and $2$  
```
mfp, xpowers(-1 -.5 1 2): regress y x1 x2 x3
```
Allow a maximum of 2 degrees of freedom for all covariates  
```
mfp, dfdefault(2): regress y x1 x2 x3
```
Allow 4 degrees of freedom for `x1` and 2 degrees of freedom for `x2` and `x3`  
```
mfp, dfdefault(2) df(x1:4): regress y x1 x2 x3
```
Same as above  
```
mfp, df(x1:4, x2 x3:2): regress y x1 x2 x3
```
Use a 10% significance level when testing between fractional polynomials of different degrees  
```
mfp, alpha(0.1): regress y x1 x2 x3
```
Perform backward selection using a nominal $p$-value of 0.05 for all variables  
```
mfp, select(0.05): regress y x1 x2 x3
```
As above, but force `x3` into the model by setting its nominal $p$-value to 1  
```
mfp, select(0.05, x3:1): regress y x1 x2 x3
```

Note: In the above examples, `regress` could be replaced with any estimation command allowing the `mfp` prefix.

All weight types supported by `regression_cmd` are allowed; see [U] 11.1.6 weight.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
`fp generate` may be used to create new variables containing fractional polynomial powers. See [R] fp.
where

\textit{regression\_cmd} may be \texttt{clogit}, \texttt{glm}, \texttt{intreg}, \texttt{logistic}, \texttt{logit}, \texttt{mlogit}, \texttt{nbreg}, \texttt{ologit}, \texttt{oiprobit}, \texttt{poisson}, \texttt{probit}, \texttt{qreg}, \texttt{regress}, \texttt{rreg}, \texttt{stcox}, \texttt{stcrreg}, \texttt{streg}, or \texttt{xtgee}.

\textit{yvar\_1} is not allowed for \texttt{streg}, \texttt{stcrreg}, and \texttt{stcox}. For these commands, you must first \texttt{stset} your data.

\textit{yvar\_1} and \textit{yvar\_2} must both be specified when \textit{regression\_cmd} is \texttt{intreg}.

\textit{xvarlist} has elements of type \texttt{varlist} and/or (\texttt{varlist}), for example, \texttt{x1 x2 (x3 x4 x5)}

Elements enclosed in parentheses are tested jointly for inclusion in the model and are not eligible for fractional polynomial transformation.

\section*{Options}

\begin{itemize}
  \item \texttt{sequential} chooses the sequential fractional polynomial (FP) selection algorithm (see Methods of FP model selection).
  \item \texttt{cycles(\#)} sets the maximum number of iteration cycles permitted. \texttt{cycles(5)} is the default.
  \item \texttt{dfdefault(\#)} determines the default maximum degrees of freedom (df) for a predictor. The default is \texttt{dfdefault(4)} (second-degree FP).
  \item \texttt{center(cent\_list)} defines the centering of the covariates \texttt{xvar\_1}, \texttt{xvar\_2}, \ldots of \texttt{xvarlist}. The default is \texttt{center(mean)}, except for binary covariates, where it is \texttt{center(\#)}, with \# being the lower of the two distinct values of the covariate. A typical item in \texttt{cent\_list} is \texttt{varlist:}\{\texttt{mean|\#|no}\}. Items are separated by commas. The first item is special in that \texttt{varlist} is optional, and if it is omitted, the default is reset to the specified value (\texttt{mean}, \#, or \texttt{no}). For example, \texttt{center(no, age:mean)} sets the default to \texttt{no} (that is, no centering) and the centering of \texttt{age} to \texttt{mean}.
  \item \texttt{alpha(alpha\_list)} sets the significance levels for testing between FP models of different degrees. The rules for \texttt{alpha\_list} are the same as those for \texttt{df\_list} in the \texttt{df()} option (see below). The default nominal \(p\)-value (significance level, selection level) is 0.05 for all variables.
    \begin{itemize}
      \item Example: \texttt{alpha(0.01)} specifies that all variables have an FP selection level of 1%.
      \item Example: \texttt{alpha(0.05, weight:0.1)} specifies that all variables except \texttt{weight} have an FP selection level of 5%; \texttt{weight} has a level of 10%.
    \end{itemize}
  \item \texttt{df(df\_list)} sets the df for each predictor. The df (not counting the regression constant, \_cons) is twice the degree of the FP, so, for example, an \texttt{xvar} fit as a second-degree FP (FP2) has 4 df. The first item in \texttt{df\_list} may be either \# or \texttt{varlist:\#}. Subsequent items must be \texttt{varlist:\#}. Items are separated by commas, and \texttt{varlist} is specified in the usual way for variables. With the first type of item, the df for all predictors is taken to be \#. With the second type of item, all members of \texttt{varlist} (which must be a subset of \texttt{xvarlist}) have \# df.
    \begin{itemize}
      \item The default number of degrees of freedom for a predictor of type \texttt{varlist} specified in \texttt{xvarlist} but not in \texttt{df\_list} is assigned according to the number of distinct (unique) values of the predictor, as follows:
      \begin{table}
        \begin{tabular}{|c|c|}
          \hline
          # of distinct values & Default df \\
          \hline
          1 & (invalid predictor) \\
          2–3 & 1 \\
          4–5 & \text{min}(2, dfdefault()) \\
          \geq 6 & dfdefault() \\
          \hline
        \end{tabular}
      \end{table}
    \end{itemize}
\end{itemize}
Example: \texttt{df(4)}
All variables have 4 df.

Example: \texttt{df(2, weight displ:4)}
weight and displ have 4 df; all other variables have 2 df.

Example: \texttt{df(weight displ:4, mpg:2)}
weight and displ have 4 df, mpg has 2 df; all other variables have default df.

\texttt{powers(numlist)} is the set of FP powers to be used. The default set is $-2, -1, -0.5, 0, 0.5, 1, 2, 3$ (0 means log).

\texttt{xorder(+|-|n)} determines the order of entry of the covariates into the model-selection algorithm. The default is \texttt{xorder(+)}, which enters them in decreasing order of significance in a multiple linear regression (most significant first). \texttt{xorder(-)} places them in reverse significance order, whereas \texttt{xorder(n)} respects the original order in \texttt{xvarlist}.

\texttt{select(select_list)} sets the nominal $p$-values (significance levels) for variable selection by backward elimination. A variable is dropped if its removal causes a nonsignificant increase in deviance. The rules for \texttt{select_list} are the same as those for \texttt{df_list} in the \texttt{df()} option (see above). Using the default selection level of 1 for all variables forces them all into the model. Setting the nominal $p$-value to be 1 for a given variable forces it into the model, leaving others to be selected or not. The nominal $p$-value for elements of \texttt{xvarlist} bound by parentheses is specified by including (\texttt{varlist}) in \texttt{select_list}.

Example: \texttt{select(0.05)}
All variables have a nominal $p$-value of 5%.

Example: \texttt{select(0.05, weight:1)}
All variables except weight have a nominal $p$-value of 5%; weight is forced into the model.

Example: \texttt{select(a (b c):0.05)}
All variables except a, b, and c are forced into the model. b and c are tested jointly with 2 df at the 5% level, and a is tested singly at the 5% level.

\texttt{xpowers(xp_list)} sets the permitted FP powers for covariates individually. The rules for \texttt{xp_list} are the same as for \texttt{df_list} in the \texttt{df()} option. The default selection is the same as that for the \texttt{powers()} option.

Example: \texttt{xpowers(-1 0 1)}
All variables have powers $-1, 0, 1$.

Example: \texttt{xpowers(x5:-1 0 1)}
All variables except x5 have default powers; x5 has powers $-1, 0, 1$.

\texttt{zero(varlist)} treats negative and zero values of members of \texttt{varlist} as zero when FP transformations are applied. By default, such variables are subjected to a preliminary linear transformation to avoid negative and zero values, as described in the \texttt{scale} option of [R] fp. \texttt{varlist} must be part of \texttt{xvarlist}.

\texttt{catzero(varlist)} is a variation on \texttt{zero()}; see \texttt{Zeros and zero categories} below. \texttt{varlist} must be part of \texttt{xvarlist}.

\texttt{regression_cmd_options} may be any of the options appropriate to \texttt{regression_cmd}.

\texttt{all} includes out-of-sample observations when generating the FP variables. By default, the generated FP variables contain missing values outside the estimation sample.
Reporting

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [U] 20.7 Specifying the width of confidence intervals.

display_options: cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch; see [R] estimation options.

Remarks and examples

Remarks are presented under the following headings:

Iteration report
Estimation algorithm
Methods of FP model selection
Zeros and zero categories

For elements in xvarlist not enclosed in parentheses, mfp leaves variables in the data named Ixvar_1, Ixvar_2, ..., where xvar represents the first four letters of the name of xvar_1, and so on, for xvar_2, xvar_3, etc. The new variables contain the best-fitting FP powers of xvar_1, xvar_2, ....

Iteration report

By default, for each continuous predictor, x, mfp compares null, linear, and FP1 models for x with an FP2 model. The deviance for each of these nested submodels is given in the column labeled “Deviance”. The line labeled “Final” gives the deviance for the selected model and its powers. All the other predictors currently selected are included, with their transformations (if any). For models specified as having 1 df, the only choice is whether the variable enters the model.

Estimation algorithm

The estimation algorithm in mfp processes the xvars in turn. Initially, mfp silently arranges xvarlist in order of increasing p-value (that is, of decreasing statistical significance) for omitting each predictor from the model comprising xvarlist, with each term linear. The aim is to model relatively important variables before unimportant ones. This approach may help to reduce potential model-fitting difficulties caused by collinearity or, more generally, “concurvity” among the predictors. See the xorder() option above for details on how to change the ordering.

At the initial cycle, the best-fitting FP function for xvar_1 (the first of xvarlist) is determined, with all the other variables assumed to be linear. Either the default or the alternative procedure is used (see Methods of FP model selection below). The functional form (but not the estimated regression coefficients) for xvar_1 is kept, and the process is repeated for xvar_2, xvar_3, etc. The first iteration concludes when all the variables have been processed in this way. The next cycle is similar, except that the functional forms from the initial cycle are retained for all variables except the one currently being processed.

A variable whose functional form is prespecified to be linear (that is, to have 1 df) is tested for exclusion within the above procedure when its nominal p-value (selection level) according to select() is less than 1; otherwise, it is included.

Updating of FP functions and candidate variables continues until the functions and variables included in the overall model do not change (convergence). Convergence is usually achieved within 1–4 cycles.
Methods of FP model selection

**mfp** includes two algorithms for FP model selection, both of which combine backward elimination with the selection of an FP function. For each continuous variable in turn, they start from a most-complex permitted FP model and attempt to simplify the model by reducing the degree. The default algorithm resembles a closed-test procedure, a sequence of tests maintaining the overall type I error rate at a prespecified nominal level, such as 5%. All significance tests are approximate; therefore, the algorithm is not precisely a closed-test procedure (Royston and Sauerbrei 2008, chap. 6).

The closed-test algorithm for choosing an FP model with maximum permitted degree $m = 2$ (that is, an FP2 model with 4 df) for one continuous predictor, $x$, is as follows:

1. **Inclusion**: Test $\text{FP}_2$ against the null model for $x$ on 4 df at the significance level determined by `select()`. If $x$ is significant, continue; otherwise, drop $x$ from the model.
2. **Nonlinearity**: Test $\text{FP}_2$ against a straight line in $x$ on 3 df at the significance level determined by `alpha()`. If significant, continue; otherwise, stop, with the chosen model for $x$ being a straight line.
3. **Simplification**: Test $\text{FP}_2$ against $\text{FP}_1$ on 2 df at the significance level determined by `alpha()`. If significant, the final model is $\text{FP}_2$; otherwise, it is $\text{FP}_1$.

The first step is omitted if $x$ is to be retained in the model, that is, if its nominal $p$-value, according to the `select()` option, is 1.

An alternative algorithm is available with the `sequential` option, as originally suggested by Royston and Altman (1994):

1. Test $\text{FP}_2$ against $\text{FP}_1$ on 2 df at the `alpha()` significance level. If significant, the final model is $\text{FP}_2$; otherwise, continue.
2. Test $\text{FP}_1$ against a straight line on 1 df at the `alpha()` level. If significant, the final model is $\text{FP}_1$; otherwise, continue.
3. Test a straight line against omitting $x$ on 1 df at the `select()` level. If significant, the final model is a straight line; otherwise, drop $x$.

The final step is omitted if $x$ is to be retained in the model, that is, if its nominal $p$-value, according to the `select()` option, is 1.

If $x$ is uninfluential, the overall type I error rate of this procedure is about double that of the closed-test procedure, for which the rate is close to the nominal value. This inflated type I error rate confers increased apparent power to detect nonlinear relationships.

**Zeros and zero categories**

The `zero()` option permits fitting an FP model to the positive values of a covariate, taking nonpositive values as zero. An application is the assessment of the effect of cigarette smoking as a risk factor in an epidemiological study. Nonsmokers may be qualitatively different from smokers, so the effect of smoking (regarded as a continuous variable) may not be continuous between one and zero cigarettes. To allow for this, the risk may be modeled as constant for the nonsmokers and as an FP function of the number of cigarettes for the smokers:

```
. generate byte nonsmkr = cond(n_cigs==0, 1, 0) if n_cigs != .
. mfp, zero(n_cigs) df(4, nonsmkr:1): logit case n_cigs nonsmkr age
```

Omission of `zero(n_cigs)` would cause `n_cigs` to be transformed before analysis by the addition of a suitable constant, probably 1.
A closely related approach involves the `catzero()` option. The command

```
. mfp, catzero(n_cigs): logit case n_cigs age
```

would achieve a similar result to the previous command but with important differences. First, `mfp` would create the equivalent of the binary variable `nonsmokr` automatically and include it in the model. Second, the two smoking variables would be treated as one predictor in the model. With the `select()` option active, the two variables would be tested jointly for inclusion in the model. A modified version is described in Royston and Sauerbrei (2008, sec. 4.15).

Example 1

We illustrate two of the analyses performed by Sauerbrei and Royston (1999). We use `brcancer.dta`, which contains prognostic factors data from the German Breast Cancer Study Group of patients with node-positive breast cancer. The response variable is recurrence-free survival time (`rectime`), and the censoring variable is `censrec`. There are 686 patients with 299 events. We use Cox regression to predict the log hazard of recurrence from prognostic factors of which five are continuous (`x1`, `x3`, `x5`, `x6`, `x7`) and three are binary (`x2`, `x4a`, `x4b`). Hormonal therapy (`hormon`) is known to reduce recurrence rates and is forced into the model. We use `mfp` to build a model from the initial set of eight predictors by using the backfitting model-selection algorithm. We set the nominal $p$-value for variable and FP selection to 0.05 for all variables except `hormon`, which it is set to 1:

```
. use http://www.stata-press.com/data/r14/brcancer
(Stata breast cancer data)
. stset rectime, fail(censrec)
(output omitted)
```
. mfp, alpha(.05) select(.05, hormon:1): stcox x1 x2 x3 x4a x4b x5 x6 x7 hormon, > nohr

Deviance: 3420.724.

Some explanation of the output from the model-selection algorithm is desirable. Consider the first few lines of output in the iteration log:

1. Deviance for model with all terms untransformed = 3471.637, 686 observations

<table>

</tbody>
</table>

Line 1 gives the deviance (−2 × log partial likelihood) for the Cox model with all terms linear, the place where the algorithm starts. The model is modified variable by variable in subsequent steps. The most significant linear term turns out to be x5, which is therefore processed first. Line 2 compares the best-fitting FP2 for x5 with a model omitting x5. The FP has powers (0.5, 3), and the test for inclusion of x5 is highly significant. The reported deviance of 3,503.610 is of the null model, not for the FP2 model. The deviance for the FP2 model may be calculated by subtracting the deviance
difference (Dev diff.) from the reported deviance, giving $3,503.610 - 61.366 = 3,442.244$. Line 3 shows that the FP2 model is also a significantly better fit than a straight line (lin.) and line 4 that FP2 is also somewhat better than FP1 ($p = 0.031$). Thus at this stage in the model-selection procedure, the final model for $x5$ (line 5) is FP2 with powers $(0.5, 3)$. The overall model with an FP2 for $x5$ and all other terms linear has a deviance of $3,442.244$.

After all the variables have been processed (cycle 1) and reprocessed (cycle 2) in this way, convergence is achieved because the functional forms (FP powers and variables included) after cycle 2 are the same as they were after cycle 1. The model finally chosen is Model II as given in tables 3 and 4 of Sauerbrei and Royston (1999). Because of scaling of variables, the regression coefficients reported there are different, but the model and its deviance are identical. The model includes $x1$ with powers $(-2, -0.5)$, $x4a$, $x5$ with powers $(-2, -1)$, and $x6$ with power 0.5. There is strong evidence of nonlinearity for $x1$ and for $x5$, the deviance differences for comparison with a straight-line model (FP2 vs lin.) being, respectively, 19.3 and 31.1 at convergence (cycle 2). Predictors $x2$, $x3$, $x4b$, and $x7$ are dropped, as may be seen from their status out in the table Final multivariable fractional polynomial model for $t$ (the assumed depvar when using stcox).

All predictors except $x4a$ and hormon, which are binary, have been centered on the mean of the original variable. For example, the mean of $x1$ (age) is 53.05 years. The first FP-transformed variable for $x1$ is $x1^{-2}$ and is created by the expression `generate double Ix1__1 = X^-2-.0355 if e(sample)`. The value 0.0355 is obtained from $(53.05/10)^{-2}$. The division by 10 is applied automatically to improve the scaling of the regression coefficient for $Ix1__1$.

According to Sauerbrei and Royston (1999), medical knowledge dictates that the estimated risk function for $x5$ (number of positive nodes), which was based on the above FP with powers $(-2, -1)$, should be monotonic, but it was not. They improved Model II by estimating a preliminary exponential transformation, $x5e = \exp(-0.12 \cdot x5)$, for $x5$ and fitting a degree 1 FP for $x5e$, thus obtaining a monotonic risk function. The value of $-0.12$ was estimated univariately using nonlinear Cox regression with the ado-file `boxtid` (Royston and Ambler 1999b, 1999d). To ensure a negative exponent, Sauerbrei and Royston (1999) restricted the powers for $x5e$ to be positive. Their Model III may be fit by using the following command:

```
. mfp, alpha(.05) select(.05, hormon:1) df(x5e:2) xpowers(x5e:0.5 1 2 3):
  > stcox x1 x2 x3 x4a x4b x5e x6 x7 hormon
```

Other than the customization for $x5e$, the command is the same as it was before. The resulting model is as reported in table 4 of Sauerbrei and Royston (1999):
. use http://www.stata-press.com/data/r14/brcancer, clear
(German breast cancer data)
. stset rectime, fail(censrec)
(output omitted)
. mfp, alpha(.05) select(.05, hormon:1) df(x5e:2) xpowers(x5e:0.5 1 2 3):
> stcox x1 x2 x3 x4a x4b x5e x6 x7 hormon, nohr
(output omitted)

Deviance: 3423.237.
Stored results

In addition to what `regression_cmd` stores, `mfp` stores the following in `e()`:

Scalars
- `e(fp_nx)` number of predictors in `xvarlist`
- `e(fp_dev)` deviance of final model fit
- `e(Fp_id#)` initial degrees of freedom for the #th element of `xvarlist`
- `e(Fp_fd#)` final degrees of freedom for the #th element of `xvarlist`
- `e(Fp_al#)` FP selection level for the #th element of `xvarlist`
- `e(Fp_se#)` backward elimination selection level for the #th element of `xvarlist`

Macros
- `e(fp_cmd)` `fracpoly`
- `e(fp_cmd2)` `mfp`
- `e(cmdline)` command as typed
- `e(frcapoly)` command used to fit the selected model using `fracpoly`
- `e(fp_fvl)` variables in final model
- `e(fp_depv)` `yvar_1 (yvar_2)`
- `e(fp_opts)` estimation command options
- `e(fp_x1)` first variable in `xvarlist`
- `e(fp_x2)` second variable in `xvarlist`
  ...
- `e(fp_xN)` last variable in `xvarlist`, `N=e(fp_nx)`
- `e(fp_k1)` power for first variable in `xvarlist` (*)
- `e(fp_k2)` power for second variable in `xvarlist` (*)
  ...
- `e(fp_kN)` power for last var. in `xvarlist` (*), `N=e(fp_nx)`

Note: (*) contains ‘.’ if the variable is not selected in the final model.

Acknowledgments

`mfp` is an update of `mfracpol` by Royston and Ambler (1998).

fracplot and fracpred

Description for fracplot and fracpred

fracplot plots the data and fit, with 95% confidence limits, from the most recently fit fractional polynomial (FP) model. The data and fit are plotted against varname, which may be xvar1 or another of the covariates (xvar2, ..., or a variable from xvarlist). If varname is not specified, xvar1 is assumed.

fracpred creates newvar containing the fitted index or deviance residuals for the whole model, or the fitted index or its standard error for varname, which may be xvar1 or another covariate.

Menu for fracplot and fracpred

fracplot

Statistics > Linear models and related > Fractional polynomials > Multivariable fractional polynomial plot

fracpred

Statistics > Linear models and related > Fractional polynomials > Multivariable fractional polynomial prediction

Syntax for fracplot and fracpred

Plot data and fit from most recently fit fractional polynomial model

fracplot [ varname ] [ if ] [ in ] [ , fracplot_options ]

Create variable containing the prediction, deviance residuals, or SEs of fitted values

fracpred newvar [ , fracpred_options ]

fracplot_options

</table>
fracpred_options | Description
--- | ---
\texttt{for(varname)} | compute prediction for \textit{varname}
dresid | compute deviance residuals
stdp | compute standard errors of the fitted values \textit{varname}

\texttt{fracplot} is not allowed after \texttt{mfp} with \texttt{clogit}, \texttt{mlogit}, or \texttt{stcrreg}. \texttt{fracpred}, \texttt{dresid} is not allowed after \texttt{mfp} with \texttt{clogit}, \texttt{mlogit}, or \texttt{stcrreg}.

Options for fracplot

- \textit{Plot}

  \textit{marker_options} affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see \texttt{[G-3] marker_options}.

  \textit{marker_label_options} specify if and how the markers are to be labeled; see \texttt{[G-3] marker_label_options}.

- \textit{Fitted line}

  \textit{lineopts(cline_options)} affect the rendition of the fitted line; see \texttt{[G-3] cline_options}.

- \textit{CI plot}

  \textit{ciopts(area_options)} affect the rendition of the confidence bands; see \texttt{[G-3] area_options}.

- \textit{Add plots}

  \textit{addplot(plot)} provides a way to add other plots to the generated graph. See \texttt{[G-3] addplot_option}.

- \textit{Y axis, X axis, Titles, Legend, Overall}

  \textit{twoway_options} are any of the options documented in \texttt{[G-3] twoway_options}, excluding \texttt{by()}. These include options for titling the graph (see \texttt{[G-3] title_options}) and for saving the graph to disk (see \texttt{[G-3] saving_option}.

Options for fracpred

\texttt{for(varname)} specifies (partial) prediction for variable \textit{varname}. The fitted values are adjusted to the value specified by the \texttt{center()} option in \texttt{mfp}.

\texttt{dresid} specifies that deviance residuals be calculated.

\texttt{stdp} specifies calculation of the standard errors of the fitted values \textit{varname}, adjusted for all the other predictors at the values specified by \texttt{center()}.

Remarks and examples

\texttt{fracplot} actually produces a component-plus-residual plot. For normal-error models with constant weights and one covariate, this amounts to a plot of the observations with the fitted line inscribed. For other normal-error models, weighted residuals are calculated and added to the fitted values.
For models with additional covariates, the line is the partial linear predictor for the variable in question (xvar or a covariate) and includes the intercept $\beta_0$.

For generalized linear and Cox models, the fitted values are plotted on the scale of the “index” (linear predictor). Deviance residuals are added to the (partial) linear predictor to give component-plus-residual values. These values are plotted as small circles.

> Example 1

In example 1 of [R] mfp, we used Cox regression to predict the log hazard of breast cancer recurrence from prognostic factors of which five are continuous (x1, x3, x5, x6, x7) and three are binary (x2, x4a, x4b). We also controlled for hormonal therapy (hormon). We used mfp to build a model from the initial set of eight predictors by using the backfitting model-selection algorithm. The nominal $p$-value for variable and FP selection was set to 0.05 for all variables except hormon, which is set to 1.

```
. use http://www.stata-press.com/data/r14/brcancer
   (German breast cancer data)
. stset rectime, fail(censrec)
   (output omitted)
. mfp, alpha(.05) select(.05, hormon:1): stcox x1 x2 x3 x4a x4b x5 x6 x7 hormon,
   > nohr
   (output omitted)
```

We can use fracplot to produce component-plus-residual plots of the continuous variables. We produce the component-plus-residual plot for x1 with fracplot by specifying x1 after the command name.

```
. fracplot x1
```

We use fracpred with the stdp option to predict the standard error of the fractional polynomial prediction for x1. The standard error prediction will be stored in variable sepx1. We specify that prediction is made for x1 with the for() option. After prediction, we use summarize to show how the standard error estimate varies over different values of x1.

```
. fracpred x1
```
Methods and formulas

The general definition of an FP, accommodating possible repeated powers, may be written for functions $H_1(x), \ldots, H_m(x)$ as

$$
\beta_0 + \sum_{j=1}^{m} \beta_j H_j(x)
$$

where $H_1(x) = x^{(p_1)}$ and for $j = 2, \ldots, m$,

$$
H_j(x) = \begin{cases} 
    x^{(p_j)} & \text{if } p_j \neq p_{j-1} \\
    H_{j-1}(x) \log x & \text{if } p_j = p_{j-1}
\end{cases}
$$

For example, an FP of degree 3 with powers $(1, 3, 3)$ has $H_1(x) = x$, $H_2(x) = x^3$, and $H_3(x) = x^3 \log x$ and equals $\beta_0 + \beta_1 x + \beta_2 x^3 + \beta_3 x^3 \log x$.

The component-plus-residual values graphed by fracplot are calculated as follows: Let the data consist of triplets $(y_i, x_i, z_i)$, $i = 1, \ldots, n$, where $z_i$ is the vector of covariates for the $i$th observation, after applying possible fractional polynomial transformation and adjustment as described earlier. Let $\hat{\eta}_i = \hat{\beta}_0 + \{H(x_i) - H(x_0)\}' \hat{\beta} + z_i' \hat{\gamma}$ be the linear predictor from the FP model, as given by the fracpred command or, equivalently, by the predict command with the xb option, following mfp. Here $H(x_i) = \{H_1(x_i), \ldots, H_m(x_i)\}'$ is the vector of FP functions described above, $H(x_0) = \{H_1(x_0), \ldots, H_m(x_0)\}'$ is the vector of adjustments to $x_0$ (often, $x_0$ is chosen to be the mean of the $x_i$), $\hat{\beta}$ is the estimated parameter vector, and $\hat{\gamma}$ is the estimated parameter vector for the covariates. The values $\hat{\eta}_i^* = \hat{\beta}_0 + \{H(x_i) - H(x_0)\}' \hat{\beta}$ represent the behavior of the FP model for $x$ at fixed values $z = 0$ of the (adjusted) covariates. The $i$th component-plus-residual is defined as $\hat{\eta}_i^* + d_i$, where $d_i$ is the deviance residual for the $i$th observation. For normal-errors models, $d_i = \sqrt{w_i}(y_i - \hat{\eta}_i)$, where $w_i$ is the case weight (or 1, if weight is not specified). For logistic, Cox, and generalized linear regression models, see [R] logistic, [R] probit, [ST] stcox, and [R] glm for the formula for $d_i$. The formula for poisson models is the same as that for glm with family(poisson). For stcox, $d_i$ is the partial martingale residual (see [ST] stcox postestimation).

fracplot plots the values of $d_i$ and the curve represented by $\hat{\eta}_i^*$ against $x_i$. The confidence interval for $\hat{\eta}_i^*$ is obtained from the variance–covariance matrix of the entire model and takes into account the uncertainty in estimating $\beta_0$, $\beta$, and $\gamma$ (but not in estimating the FP powers for $x$).

fracpred with the for(varname) option calculates the predicted index at $x_i = x_0$ and $z_i = 0$; that is, $\hat{\eta}_i = \hat{\beta}_0 + \{H(x_i) - H(x_0)\}' \hat{\beta}$. The standard error is calculated from the variance–covariance matrix of $(\hat{\beta}_0, \hat{\beta})$, again ignoring estimation of the powers.

misstable — Tabulate missing values

Description

misstable makes tables that help you understand the pattern of missing values in your data.

Quick start

Tables with counts of missing values

Missing observations in v1, v2, and v3
misstable summarize v1 v2 v3

Missing observations in v1–v3 for cases where v4 > 10
misstable summarize v1 v2 v3 if v4>10

All variables with missing values
misstable summarize

Include variables with no missing values in the table
misstable summarize, all

Create 3 missing-data indicator variables with prefix m for v1, v2, and v3
misstable summarize v1 v2 v3, generate(m)

Tables of missing-value patterns

Missing-value patterns for v1, v2, and v3
misstable patterns v1 v2 v3

Same as above, but for all variables with missing values
misstable patterns

Show variables in the order listed in the command
misstable patterns v1 v3 v2, asis

Show frequencies, rather than percentages, in the output
misstable patterns v1 v2 v3, frequency

Missing-value patterns displayed as trees

A tree view of missing-value patterns for v1, v2, and v3
misstable tree v1 v2 v3
For all variables with missing values
  misstable tree

Nesting patterns of missing values

Missing values for v1, v2, and v3
  misstable nested  v1  v2  v3

Same as above, but for all variables with missing values
  misstable nested

Treat extended missing values (.a, .b, ..., .z) as nonmissing
  misstable nested v1 v2 v3, exok

Menu

  Statistics  >  Summaries, tables, and tests  >  Other tables  >  Tabulate missing values
### Syntax

Report counts of missing values

```
misstable summarize [varlist] [if] [in] [, summarize_options]
```

Report pattern of missing values

```
misstable patterns [varlist] [if] [in] [, patterns_options]
```

Present a tree view of the pattern of missing values

```
misstable tree [varlist] [if] [in] [, tree_options]
```

List the nesting rules that describe the missing-value pattern

```
misstable nested [varlist] [if] [in] [, nested_options]
```

In addition, programmer’s option `nopreserve` is allowed with all syntaxes; see [P] `nopreserve option`. 
Options

Options are presented under the following headings:

Options for misstable summarize
Options for misstable patterns
Options for misstable tree
Option for misstable nested
Common options

Options for misstable summarize

all specifies that the table should include all the variables specified or all the variables in the dataset. The default is to include only numeric variables that contain missing values.

showzeros specifies that zeros in the table should display as 0 rather than being omitted.

generate(stub [, exok]) requests that a missing-value indicator newvar, a new binary variable containing 0 for complete observations and 1 for incomplete observations, be generated for every numeric variable in varlist containing missing values. If the all option is specified, missing-value indicators are created for all the numeric variables specified or for all the numeric variables in the dataset. If exok is specified within generate(), the extended missing values .a, .b, ..., .z are treated as if they do not designate missing.

For each variable in varlist, newvar is the corresponding variable name varname prefixed with stub. If the total length of stub and varname exceeds 128 characters, newvar is abbreviated so that its name does not exceed 128 characters.

Options for misstable patterns

asis, frequency, and exok – see Common options below.

replace specifies that the data in memory be replaced with a dataset corresponding to the table just displayed; see misstable patterns under Remarks and examples below.

clear is for use with replace; it specifies that it is okay to change the data in memory even if they have not been saved to disk.

bypatterns specifies the table be ordered by pattern rather than by frequency. That is, bypatterns specifies that patterns containing one incomplete variable be listed first, followed by those for two incomplete variables, and so on. The default is to list the most frequent pattern first, followed by the next most frequent pattern, etc.

Options for misstable tree

asis, frequency, and exok – see Common options below.

Option for misstable nested

exok – see Common options below.
Common options

asis specifies that the order of the variables in the table be the same as the order in which they are specified on the `misstable` command. The default is to order the variables by the number of missing values, and within that, by the amount of overlap of missing values.

frequency specifies that the table should report frequencies instead of percentages.

exok specifies that the extended missing values `.a`, `.b`, ..., `.z` should be treated as if they do not designate missing. Some users use extended missing values to designate values that are missing for a known and valid reason.

nopreserve is a programmer’s option allowed with all `misstable` commands; see [P] `nopreserve` option.

Remarks and examples

Remarks are presented under the following headings:

- `misstable summarize`
- `misstable patterns`
- `misstable tree`
- `misstable nested`
- `Execution time of misstable nested`

In what follows, we will use data from a 125-observation, fictional, student-satisfaction survey:

```
. use http://www.stata-press.com/data/r14/studentsurvey
(Student Survey)
. summarize
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>m1</td>
<td>125</td>
<td>2.456</td>
<td>.837619</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>m2</td>
<td>125</td>
<td>2.472</td>
<td>.8089818</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>age</td>
<td>122</td>
<td>18.975</td>
<td>.8763477</td>
<td>17</td>
<td>21</td>
</tr>
<tr>
<td>female</td>
<td>122</td>
<td>.525</td>
<td>.5014543</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>dept</td>
<td>116</td>
<td>2.491</td>
<td>1.226488</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>

| offcampus | 125 | .36  | .4819316 | 0    | 1   |
| comment   | 0   |      |          |      |     |

The `m1` and `m2` variables record the student’s satisfaction with teaching and with academics. `comment` is a string variable recording any comments the student might have had.
Example 1

`misstable summarize` reports counts of missing values:

```
.misstable summarize
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs=.</th>
<th>Obs&gt;.</th>
<th>Obs&lt;.</th>
<th>Unique values</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>age</td>
<td>3</td>
<td>122</td>
<td>5</td>
<td>5</td>
<td>17</td>
<td>21</td>
</tr>
<tr>
<td>female</td>
<td>3</td>
<td>122</td>
<td>2</td>
<td>2</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>dept</td>
<td>9</td>
<td>116</td>
<td>4</td>
<td>4</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>

Stata provides 27 different missing values, namely, ., .a, .b, ..., .z. The first of those, ., is often called system missing. The remaining missing values are called extended missings. The nonmissing and missing values are ordered `nonmissing < . < .a < .b < ... < .z`. Thus reported in the column “Obs=.” are counts of system missing values; in the column “Obs>.”, extended missing values; and in the column “Obs<.”, nonmissing values.

The rightmost portion of the table is included to remind you how the variables are encoded.

Our data contain seven variables and yet `misstable` reported only three of them. The omitted variables contain no missing values or are string variables. Even if we specified the varlist explicitly, those variables would not appear in the table unless we specified the `all` option.

We can also create missing-value indicators for each of the variables above using the `generate()` option:

```
   quietly misstable summarize, generate(miss_)
   describe miss_*
```

<table>
<thead>
<tr>
<th>variable name</th>
<th>storage</th>
<th>display</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>miss_age</td>
<td>byte</td>
<td>%8.0g</td>
<td>(age&gt;=.)</td>
</tr>
<tr>
<td>miss_female</td>
<td>byte</td>
<td>%8.0g</td>
<td>(female&gt;=.)</td>
</tr>
<tr>
<td>miss_dept</td>
<td>byte</td>
<td>%8.0g</td>
<td>(dept&gt;=.)</td>
</tr>
</tbody>
</table>

For each variable containing missing values, the `generate()` option creates a new binary variable containing 0 for complete observations and 1 for incomplete observations. In our example, three new missing-value indicators are generated, one for each of the incomplete variables `age`, `female`, and `dept`. The naming convention of `generate()` is to prefix the corresponding variable names with the specified stub, which is `miss_` in this example.

Missing-value indicators are useful, for example, for checking whether data are missing completely at random. They are also often used within the multiple-imputation context to identify the observed and imputed data; see [MI] intro substantive for a general introduction to multiple imputation. Within Stata's multiple-imputation commands, an incomplete value is identified by the system missing value, a dot. By default, `misstable summarize, generate()` marks the extended missing values as incomplete values, as well. You can use `exok` within `generate()` to treat extended missing values as complete when creating missing-value identifiers.
misstable patterns

Example 2

misstable patterns reports the pattern of missing values:

```
  . misstable patterns
Missing-value patterns
  (1 means complete)

  Percent  |  Pattern
  --------  |  1  2  3
  93%      |  1  1  1
  5        |  1  1  0
  2        |  0  0  0
  100%     |  -------

Variables are (1) age (2) female (3) dept
```

There are three patterns in these data: (1,1,1), (1,1,0), and (0,0,0). By default, the rows of the table are ordered by frequency. In larger tables that have more patterns, it is sometimes useful to order the rows by pattern. We could have obtained that by typing `mi misstable patterns, bypatterns`.

In a pattern, 1 indicates that all values of the variable are nonmissing and 0 indicates that all values are missing. Thus pattern (1,1,1) means no missing values, and 93% of our data have that pattern. There are two patterns in which variables are missing, (1,1,0) and (0,0,0). Pattern (1,1,0) means that age is nonmissing, female is nonmissing, and dept is missing. The order of the variables in the patterns appears in the key at the bottom of the table. Five percent of the observations have pattern (1,1,0). The remaining 2% have pattern (0,0,0), meaning that all three variables contain missing.

As with misstable summarize, only numeric variables that contain missing are listed, so had we typed `misstable patterns comments age female offcampus dept`, we still would have obtained the same table. Variables that are automatically omitted contain no missing values or are string variables.

The variables in the table are ordered from lowest to highest frequency of missing values, although you cannot see that from the information presented in the table. The variables are ordered this way even if you explicitly specify the varlist with a different ordering. Typing `misstable patterns dept female age` would produce the same table as above. Specify the asis option if you want the variables in the order in which you specify them.

You can obtain a dataset of the patterns by specifying the replace option:

```
  . misstable patterns, replace clear
Missing-value patterns
  (1 means complete)

  Percent  |  Pattern
  --------  |  1  2  3
  93%      |  1  1  1
  5        |  1  1  0
  2        |  0  0  0
  100%     |  -------

Variables are (1) age (2) female (3) dept
(summary data now in memory)
```
misstable — Tabulate missing values

.list

<table>
<thead>
<tr>
<th>_freq</th>
<th>age</th>
<th>female</th>
<th>dept</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>3</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2.</td>
<td>6</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3.</td>
<td>116</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

The differences between the dataset and the printed table are that 1) the dataset always records frequency and 2) the rows are reversed.

misstable tree

Example 3

misstable tree presents a tree view of the pattern of missing values:

.use http://www.stata-press.com/data/r14/studentsurvey, clear
(Student Survey)
.misstable tree, frequency

<table>
<thead>
<tr>
<th>Nested pattern of missing values</th>
</tr>
</thead>
<tbody>
<tr>
<td>dept</td>
</tr>
<tr>
<td>------</td>
</tr>
<tr>
<td>9</td>
</tr>
<tr>
<td>6</td>
</tr>
<tr>
<td>116</td>
</tr>
<tr>
<td>116</td>
</tr>
</tbody>
</table>

(number missing listed first)

In this example, we specified the frequency option to see the table in frequency rather than percentage terms. In the table, each column sums to the total number of observations in the data, 125. Variables are ordered from those with the most missing values to those with the least. Start with the first column. The dept variable is missing in 9 observations and, farther down, the table reports that it is not missing in 116 observations.

Go back to the first row and read across, but only to the second column. The dept variable is missing in 9 observations. Within those 9, age is missing in 3 of them and is not missing in the remaining 6. Reading down the second column, within the 116 observations that dept is not missing, age is missing in 0 and not missing in 116.

Reading straight across the first row again, dept is missing in 9 observations, and within the 9, age is missing in 3, and within the 3, female is also missing in 3. Skipping down just a little, within the 6 observations for which dept is missing and age is not missing, female is not missing, too.
Example 4

`misstable nested` lists the nesting rules that describe the missing-value pattern,

```
  . misstable nested
  1. female(3) <-> age(3) -> dept(9)
```

This line says that in observations in which `female` is missing, so is `age` missing, and vice versa, and in observations in which `age` (or `female`) is missing, so is `dept`. The numbers in parentheses are counts of the missing values. The `female` variable happens to be missing in 3 observations, and the same is true for `age`; the `dept` variable is missing in 9 observations. Thus `dept` is missing in the 3 observations for which `age` and `female` are missing, and in 6 more observations, too.

In these data, it turns out that the missing-value pattern can be summarized in one statement. In a larger dataset, you might see something like this:

```
  . misstable nested
  1. female(50) <-> age(50) -> dept(120)
  2. female(50) -> m1(58)
  3. offcampus(11)
```

`misstable nested` accounts for every missing value. In the above, in addition to `female <-> age -> dept`, we have that `female -> m1`, and we have `offcampus`, the last all by itself. The last line says that the 11 missing values in `offcampus` are not themselves nested in the missing value of any other variable, nor do they imply the missing values in another variable. In some datasets, all the statements will be of this last form.

In our data, however, we have one statement:

```
  . misstable nested
  1. female(3) <-> age(3) -> dept(9)
```

When the missing-value pattern can be summarized in one `misstable nested` statement, the pattern of missing values in the data is said to be monotone.

---

**Execution time of misstable nested**

The execution time of `misstable nested` is affected little by the number of observations but can grow quickly with the number of variables, depending on the fraction of missing values within variable. The execution time of the example above, which has 3 variables containing missing, is instant. In worst-case scenarios, with 500 variables, the time might be 25 seconds; with 1,000 variables, the execution time might be closer to an hour.

In situations where `misstable nested` takes a long time to complete, it will produce thousands of rules that will defy interpretation. A 523-variable dataset we have seen ran in 20 seconds and produced 8,040 rules. Although we spotted a few rules in the output that did not surprise us, such as the year of the date being missing implied that the month and the day were also missing, mostly the output was not helpful.

If you have such a dataset, we recommend you run `misstable` on groups of variables that you have reason to believe the pattern of missing values might be related.
Stored results

misstable summarize stores the following values of the last variable summarized in \( r() \):

Scalars
- \( r(N_{eq, dot}) \): number of observations containing .
- \( r(N_{gt, dot}) \): number of observations containing .a, .b, ...., .z
- \( r(N_{lt, dot}) \): number of observations containing nonmissing
- \( r(K_{uniq}) \): number of unique, nonmissing values
- \( r(min) \): variable's minimum value
- \( r(max) \): variable's maximum value

Macros
- \( r(vartype) \): numeric, string, or none

\( r(K_{uniq}) \) contains . if the number of unique, nonmissing values is greater than 500. \( r(vartype) \) contains none if no variables are summarized, and in that case, the value of the scalars are all set to missing (.). Programmers intending to access results after misstable summarize should specify the all option.

misstable patterns stores the following in \( r() \):

Scalars
- \( r(N_{complete}) \): number of complete observations
- \( r(N_{incomplete}) \): number of incomplete observations
- \( r(K) \): number of patterns

Macros
- \( r(vars) \): variables used in order presented

\( r(N_{complete}) \) and \( r(N_{incomplete}) \) are defined with respect to the variables specified if variables were specified and otherwise, defined with respect to all the numeric variables in the dataset. \( r(N_{complete}) \) is the number of observations that contain no missing values.

misstable tree stores the following in \( r() \):

Macros
- \( r(vars) \): variables used in order presented

misstable nested stores the following in \( r() \):

Scalars
- \( r(K) \): number of statements

Macros
- \( r(stmt1) \): first statement
- \( r(stmt2) \): second statement
- \( r(stmt'r(K)') \): last statement
- \( r(stmt1wc) \): \( r(stmt1) \) with missing-value counts
- \( r(vars) \): variables considered

A statement is encoded “varname”, “varname op varname”, or “varname op varname op varname”, and so on; \( op \) is either “->” or “<->”.

[R] tabulate twoway — Two-way table of frequencies
**Description**

`mkspline` creates variables containing a linear spline or a restricted cubic spline of an existing variable. For linear splines, knots can be user specified, equally spaced over the range of the variable, or placed at percentiles. For restricted cubic splines, also known as natural splines, knot locations are based on Harrell’s (2001) recommended percentiles or user-specified points.

**Quick start**

Linear spline of `v1` with knots at 30, 40, and 50

```plaintext
mkspline knot1 30 knot2 40 knot3 50 knot4 = v1
```

Add knots at 20 and 60

```plaintext
mkspline knot1 20 knot2 30 knot3 40 knot4 50 knot5 60 knot6 = v1
```

Define knots by quintiles

```plaintext
mkspline knot 5 = v1, pctile
```

As above, but apply frequency weight `wvar` before calculating quintiles

```plaintext
mkspline knot 5 = v1 [fweight=wvar], pctile
```

Restricted cubic spline of `v2` with default 5 knots

```plaintext
mkspline knot = v2, cubic
```

As above, but place knots at 30, 40, and 50

```plaintext
mkspline knot = v2, cubic knots(30, 40, 50)
```

**Menu**

- Data > Create or change data > Other variable-creation commands > Linear and cubic spline construction
Syntax

Linear spline with knots at specified points

\[
\text{mkspline } \text{newvar}_1 \#_1 [\text{newvar}_2 \#_2 [...]] \text{newvar}_k = \text{oldvar} [\text{if}] [\text{in}] [, \text{marginal displayknots}]
\]

Linear spline with knots equally spaced or at percentiles of data

\[
\text{mkspline } \text{stubname} \# = \text{oldvar} [\text{if}] [\text{in}] [\text{weight}] [, \text{marginal pctile displayknots}]
\]

Restricted cubic spline

\[
\text{mkspline } \text{stubname} = \text{oldvar} [\text{if}] [\text{in}] [\text{weight}], \text{cubic [nknots(#) knots(numlist)}]
\]

\[
\text{displayknots}
\]

fweights are allowed with the second and third syntax; see [U] 11.1.6 weight.

Options

Options

marginal is allowed with the first or second syntax. It specifies that the new variables be constructed so that, when used in estimation, the coefficients represent the change in the slope from the preceding interval. The default is to construct the variables so that, when used in estimation, the coefficients measure the slopes for the interval.

displayknots displays the values of the knots that were used in creating the linear or restricted cubic spline.

pctile is allowed only with the second syntax. It specifies that the knots be placed at percentiles of the data rather than being equally spaced over the range.

nknots(#) is allowed only with the third syntax. It specifies the number of knots that are to be used for a restricted cubic spline. This number must be between 3 and 7 unless the knot locations are specified using knots(). The default number of knots is 5.

knots(numlist) is allowed only with the third syntax. It specifies the exact location of the knots to be used for a restricted cubic spline. The values of these knots must be given in increasing order. When this option is omitted, the default knot values are based on Harrell’s recommended percentiles with the additional restriction that the smallest knot may not be less than the fifth-smallest value of oldvar and the largest knot may not be greater than the fifth-largest value of oldvar. If both nknots() and knots() are given, they must specify the same number of knots.

Remarks and examples

Remarks are presented under the following headings:

Linear splines

Restricted cubic splines
Linear splines

Linear splines allow estimating the relationship between $y$ and $x$ as a piecewise linear function, which is a function composed of linear segments—straight lines. One linear segment represents the function for values of $x$ below $x_0$, another linear segment handles values between $x_0$ and $x_1$, and so on. The linear segments are arranged so that they join at $x_0$, $x_1$, ..., which are called the knots. An example of a piecewise linear function is shown below.

Example 1

We wish to fit a model of log income on education and age by using a piecewise linear function for age:

$$\lninc = b_0 + b_1 \text{educ} + f(\text{age}) + u$$

The knots are to be placed at 10-year intervals: 20, 30, 40, 50, and 60.

. use http://www.stata-press.com/data/r14/mksp1
. mkspline age1 20 age2 30 age3 40 age4 50 age5 60 age6 = age, marginal
. regress lninc educ age1-age6
(output omitted)

Because we specified the `marginal` option, we could test whether the age effect is the same in the 30–40 and 40–50 intervals by asking whether the `age4` coefficient is zero. With the `marginal` option, coefficients measure the change in slope from the preceding group. Specifying `marginal` changes only the interpretation of the coefficients; the same model is fit in either case. Without the `marginal` option, the interpretation of the coefficients would have been

$$\frac{dy}{d\text{age}} = \begin{cases} 
  a_1 & \text{if } \text{age} < 20 \\
  a_2 & \text{if } 20 \leq \text{age} < 30 \\
  a_3 & \text{if } 30 \leq \text{age} < 40 \\
  a_4 & \text{if } 40 \leq \text{age} < 50 \\
  a_5 & \text{if } 50 \leq \text{age} < 60 \\
  a_6 & \text{otherwise} 
\end{cases}$$
With the marginal option, the interpretation is

$$\frac{dy}{dage} = \begin{cases} 
a_1 & \text{if age} < 20 
a_1 + a_2 & \text{if } 20 \leq \text{age} < 30 
a_1 + a_2 + a_3 & \text{if } 30 \leq \text{age} < 40 
a_1 + a_2 + a_3 + a_4 & \text{if } 40 \leq \text{age} < 50 
a_1 + a_2 + a_3 + a_4 + a_5 & \text{if } 50 \leq \text{age} < 60 
a_1 + a_2 + a_3 + a_4 + a_5 + a_6 & \text{otherwise} 
\end{cases}$$

Example 2

Say that we have a binary outcome variable called outcome. We are beginning an analysis and wish to parameterize the effect of dosage on outcome. We wish to divide the data into five equal-width groups of dosage for the piecewise linear function.

```
. use http://www.stata-press.com/data/r14/mksp2, clear
. mkspline dose 5 = dosage, displayknots
    knot1  knot2  knot3  knot4
  dosage
    20     40     60     80
. logistic outcome dose1-dose5
(output omitted)
```

The `pctile` option sets the knots to divide the data into five equal sample-size groups rather than five equal-width ranges. Typing

```
. mkspline pctdose 5 = dosage, pctile displayknots
    knot1  knot2  knot3  knot4
  dosage
    16    36.4    55.6    82
```

places the knots at the 20th, 40th, 60th, and 80th percentiles of the data.

Restricted cubic splines

A linear spline can be used to fit many functions well. However, a restricted cubic spline may be a better choice than a linear spline when working with a very curved function. When using a restricted cubic spline, one obtains a continuous smooth function that is linear before the first knot, a piecewise cubic polynomial between adjacent knots, and linear again after the last knot.
Example 3

Returning to the data from example 1, we may feel that a curved function is a better fit. First, we will use the knots() option to specify the five knots that we used previously.

```stata
use http://www.stata-press.com/data/r14/mksp1, clear
.mkspline agesp = age, cubic knots(20 30 40 50 60)
.regress lninc educ agesp*
(output omitted)
```

Harrell (2001, 23) recommends placing knots at equally spaced percentiles of the original variable’s marginal distribution. If we do not specify the knots() option, variables will be created containing a restricted cubic spline with five knots determined by Harrell’s default percentiles.

```stata
use http://www.stata-press.com/data/r14/mksp1, clear
.mkspline agesp = age, cubic displayknots
.regress lninc educ agesp*
(output omitted)
```

Methods and formulas

Methods and formulas are presented under the following headings:

- **Linear splines**
- **Restricted cubic splines**

### Linear splines

Let $V_i, i = 1, \ldots, n$, be the variables to be created; $k_i, i = 1, \ldots, n - 1$, be the corresponding knots; and $V$ be the original variable (the command is `mkspline V_1 k_1 V_2 k_2 \ldots V_n = V`). Then

\[
V_1 = \min(V, k_1)
\]

\[
V_i = \max\left\{ \min(V, k_i), k_{i-1} \right\} - k_{i-1} \quad i = 2, \ldots, n - 1
\]

\[
V_n = \max(V, k_{n-1}) - k_{n-1}
\]

If the marginal option is specified, the definitions are

\[
V_1 = V
\]

\[
V_i = \max(0, V - k_{i-1}) \quad i = 2, \ldots, n
\]

In the second syntax, `mkspline stubname # = V`, so let $m$ and $M$ be the minimum and maximum of $V$. Without the `pctile` option, knots are set at $m + (M - m)(i/n)$ for $i = 1, \ldots, n - 1$. If `pctile` is specified, knots are set at the $100(i/n)$ percentiles, for $i = 1, \ldots, n - 1$. Percentiles are calculated by `centile`; see `[R] centile`. 
## Restricted cubic splines

Let $k_i$, $i = 1, \ldots, n$, be the knot values; $V_i$, $i = 1, \ldots, n - 1$, be the variables to be created; and $V$ be the original variable. Then

$$
V_1 = V
$$

$$
V_{i+1} = \frac{(V - k_i)^3 - (k_n - k_{n-1})^{-1}\{(V - k_{n-1})^3(k_n - k_i) - (V - k_n)^3(k_{n-1} - k_i)\}}{(k_n - k_1)^2}
$$

$i = 1, \ldots, n - 2$

where

$$(u)_+ = \begin{cases} 
    u, & \text{if } u > 0 \\
    0, & \text{if } u \leq 0
  \end{cases}$$

Without the `knots()` option, the locations of the knots are determined by the percentiles recommended in Harrell (2001, 23). These percentiles are based on the chosen number of knots as follows:

<table>
<thead>
<tr>
<th>No. of knots</th>
<th>Percentiles</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>10 50 90</td>
</tr>
<tr>
<td>4</td>
<td>5 35 65 95</td>
</tr>
<tr>
<td>5</td>
<td>5 27.5 50 72.5 95</td>
</tr>
<tr>
<td>6</td>
<td>5 23 41 59 77 95</td>
</tr>
<tr>
<td>7</td>
<td>2.5 18.33 34.17 50 65.83 81.67 97.5</td>
</tr>
</tbody>
</table>

Harrell provides default percentiles when the number of knots is between 3 and 7. When using a number of knots outside this range, the location of the knots must be specified in `knots()`.

## Acknowledgment

The restricted cubic spline portion of `mkspline` is based on the `rc_spline` command by William Dupont of the Department of Biostatistics at Vanderbilt University.

[R] fp — Fractional polynomial regression
Description

`ml model` defines the current problem.

`ml clear` clears the current problem definition. This command is rarely used because when you type `ml model`, any previous problem is automatically cleared.

`ml query` displays a description of the current problem.

`ml check` verifies that the log-likelihood evaluator you have written works. We strongly recommend using this command.

`ml search` searches for (better) initial values. We recommend using this command.

`ml plot` provides a graphical way of searching for (better) initial values.

`ml init` provides a way to specify initial values.

`ml report` reports \( \ln L \)'s values, gradient, and Hessian at the initial values or current parameter estimates, \( b_0 \).

`ml trace` traces the execution of the user-defined log-likelihood evaluation program.

`ml count` counts the number of times the user-defined log-likelihood evaluation program is called; this command is seldom used. `ml count clear` clears the counter. `ml count on` turns on the counter. `ml count` without arguments reports the current values of the counter. `ml count off` stops counting calls.

`ml maximize` maximizes the likelihood function and reports results. Once `ml maximize` has successfully completed, the previously mentioned `ml` commands may no longer be used unless `noclear` is specified. `ml graph` and `ml display` may be used whether or not `noclear` is specified.

`ml graph` graphs the log-likelihood values against the iteration number.

`ml display` redisplays results.

`ml footnote` displays a warning message when the model did not converge within the specified number of iterations.

`ml score` creates new variables containing the equation-level scores. The variables generated by `ml score` are equivalent to those generated by specifying the `score()` option of `ml maximize` (and `ml model ... , ... maximize`).

`progname` is the name of a Stata program you write to evaluate the log-likelihood function.

`funcname()` is the name of a Mata function you write to evaluate the log-likelihood function.

In this documentation, `progname` and `funcname()` are referred to as the user-written evaluator, the likelihood evaluator, or sometimes simply as the evaluator. The program you write is written in the style required by the method you choose. The methods are lf, d0, d1, d2, lf0, lf1, lf2, and gf0. Thus, if you choose to use method lf, your program is called a method-lf evaluator.

Method-lf evaluators are required to evaluate the observation-by-observation log likelihood \( \ln \ell_j \), \( j = 1, \ldots, N \).
Method-d0 evaluators are required to evaluate the overall log likelihood $\ln L$. Method-d1 evaluators are required to evaluate the overall log likelihood and its gradient vector $g = \partial \ln L / \partial b$. Method-d2 evaluators are required to evaluate the overall log likelihood, its gradient, and its Hessian matrix $H = \partial^2 \ln L / \partial b \partial b'$.

Method-lf0 evaluators are required to evaluate the observation-by-observation log likelihood $\ln \ell_j$, $j = 1, \ldots, N$. Method-lf1 evaluators are required to evaluate the observation-by-observation log likelihood and its equation-level scores $g_{ji} = \partial \ln \ell / \partial x_{ji} b_i$. Method-lf2 evaluators are required to evaluate the observation-by-observation log likelihood, its equation-level scores, and its Hessian matrix $H = \partial^2 \ln \ell / \partial b \partial b'$.

Method-gf0 evaluators are required to evaluate the summable pieces of the log likelihood $\ln \ell_k$, $k = 1, \ldots, K$.

\texttt{mleval} is a subroutine used by evaluators of methods d0, d1, d2, lf0, lf1, lf2, and gf0 to evaluate the coefficient vector, $b$, that they are passed.

\texttt{mlsum} is a subroutine used by evaluators of methods d0, d1, and d2 to define the value, $\ln L$, that is to be returned.

\texttt{mlvecsum} is a subroutine used by evaluators of methods d1 and d2 to define the gradient vector, $g$, that is to be returned. It is suitable for use only when the likelihood function meets the linear-form restrictions.

\texttt{mlmatsum} is a subroutine used by evaluators of methods d2 and lf2 to define the Hessian matrix, $H$, that is to be returned. It is suitable for use only when the likelihood function meets the linear-form restrictions.

\texttt{mlmatbysum} is a subroutine used by evaluator of method d2 to help define the Hessian matrix, $H$, that is to be returned. It is suitable for use when the likelihood function contains terms made up of grouped sums, such as in panel-data models. For such models, use \texttt{mlmatsum} to compute the observation-level outer products and \texttt{mlmatbysum} to compute the group-level outer products. \texttt{mlmatbysum} requires that the data be sorted by the variable identified in the \texttt{by()} option.

\section*{Syntax}

\texttt{ml model in interactive mode}

\begin{verbatim}
ml model method programe eq [eq ...] [if] [in] [weight]
    [ , model_options svy diparm_options]
\end{verbatim}

\begin{verbatim}
ml model method funcname() eq [eq ...] [if] [in] [weight]
    [ , model_options svy diparm_options]
\end{verbatim}

\texttt{ml model in noninteractive mode}

\begin{verbatim}
ml model method programe eq [eq ...] [if] [in] [weight] , maximize
    [model_options svy diparm_options noninteractive_options]
\end{verbatim}

\begin{verbatim}
ml model method funcname() eq [eq ...] [if] [in] [weight] , maximize
    [model_options svy diparm_options noninteractive_options]
\end{verbatim}
Noninteractive mode is invoked by specifying the `maximize` option. Use `maximize` when `ml` will be used as a subroutine of another ado-file or program and you want to carry forth the problem, from definition to posting of results, in one command.

```
ml clear
ml_query
ml_check
ml_search [ [ / ] eqname[ : ] #lb #ub ] [...] [, search_options]
ml_init { [ eqname : ] name=#| / eqname=# } [...]  
ml_init # [ # ...], copy
ml_init matname [, copy skip]
ml_report
ml_trace { on | off }
ml_count [ clear | on | off]
ml_maximize [ , ml_maximize_options display_options eform_option]
ml_graph [ # ] [, saving(filename[, replace])]
ml_display [, display_options eform_option]
ml_footnote
ml_score newvar [ if ] [ in ] [, equation(eqname) missing]
ml_score newvarlist [ if ] [ in ] [, missing]
ml_score [ type ] stub* [ if ] [ in ] [, missing]
```

where `method` is one of

```
lf    d0        lf0        gf0
  d1    lf1
d1debug   lf1debug
  d2    lf2
d2debug   lf2debug
```
or `method` can be specified using one of the longer, more descriptive names

<table>
<thead>
<tr>
<th>method</th>
<th>Longer name</th>
</tr>
</thead>
<tbody>
<tr>
<td>lf</td>
<td>linearform</td>
</tr>
<tr>
<td>d0</td>
<td>derivative0</td>
</tr>
<tr>

</tr>
<tr>
<td>lf2</td>
<td>linearform2</td>
</tr>
<tr>
<td>lf2debug</td>
<td>linearform2debug</td>
</tr>
<tr>
<td>gf0</td>
<td>generalform0</td>
</tr>
</tbody>
</table>

`eq` is the equation to be estimated, enclosed in parentheses, and optionally with a name to be given to the equation, preceded by a colon,

```
(eqname: [varlist_y =] [varlist_x] [ , eq_options])
```

or `eq` is the name of a parameter, such as sigma, with a slash in front

```
/eqname
```

and `diparm_options` is one or more `diparm(diparm_args)` options where `diparm_args` is either `__sep__` or anything accepted by the “undocumented” `diparm` command; see help `diparm`.

### eform_option Description

- **eform**(string) display exponentiated coefficients; column title is “string”
- **eform** display exponentiated coefficients; column title is “exp(b)”
- **hr** report hazard ratios
- **shr** report subhazard ratios
- **irr** report incidence-rate ratios
- **or** report odds ratios
- **rrr** report relative-risk ratios

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight. With all but method lf, you must write your likelihood-evaluation program carefully if pweights are to be specified, and pweights may not be specified with method d0, d1, d1debug, d2, or d2debug. See Gould, Pitblado, and Poi (2010, chap. 6) for details.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

To redisplay results, type `ml display`.

### Syntax of subroutines for use by evaluator programs

```
# Syntax of subroutines for use by evaluator programs

mleval newvar = vecname [, eq(#)]
# mleval scalarname = vecname, scalar [eq(#)]
# mlsum scalarname_{lnf} = exp [if] [, noweight]
# mlvecsum scalarname_{lnf} rowvecname = exp [if] [, eq(#)]
# mlmatsum scalarname_{lnf} matrixname = exp [if] [, eq(#[,#])] # mlmatbysum scalarname_{lnf} matrixname varname_{a} varname_{b} [varname_{c}] [if] ,
# by(varname) [ eq(#[,#])] #
```

### Syntax of user-written evaluator

#### Summary of notation

The log-likelihood function is \( \ln L(\theta_{1j}, \theta_{2j}, \ldots, \theta_{Ej}) \), where \( \theta_{ij} = x_{ij} b_i \), \( j = 1, \ldots, N \) indexes observations, and \( i = 1, \ldots, E \) indexes the linear equations defined by `ml model`. If the likelihood satisfies the linear-form restrictions, it can be decomposed as \( \ln L = \sum_{j=1}^{N} \ln \ell(\theta_{1j}, \theta_{2j}, \ldots, \theta_{Ej}) \).

#### Method-lf evaluators

```
# Syntax of user-written evaluator

program proglename
    version 14.2
    args lnfj thetai1 thetai2 ...
    // if you need to create any intermediate results:
    tempvar tmp1 tmp2 ...
    quietly generate double ‘tmp1’ = ...
    ...
    quietly replace ‘lnfj’ = ...
    end
```
where

- `'lnfj'` variable to be filled in with observation-by-observation values of \( \ln \ell_j \)
- `'theta1'` variable containing evaluation of first equation \( \theta_{1j} = x_{1j} b_1 \)
- `'theta2'` variable containing evaluation of second equation \( \theta_{2j} = x_{2j} b_2 \)

### Method-d0 evaluators

```plaintext
program programe
    version 14.2
    args todo b lnf
    tempvar theta1 theta2 ...
    mleval `theta1' = 'b', eq(1)
    mleval `theta2' = 'b', eq(2) // if there is a \( \theta_2 \)
    ...
    // if you need to create any intermediate results:
    tempvar tmp1 tmp2 ...
    generate double `tmp1' = ...
    ...
    mlsum `lnf' = ...
end
```

where

- `'todo'` always contains 0 (may be ignored)
- `'b'` full parameter row vector \( b = (b_1, b_2, \ldots, b_E) \)
- `'lnf'` scalar to be filled in with overall \( \ln L \)

### Method-d1 evaluators

if ('todo'==1) exit 
tempname d11 d12 d22 lnf ... 
mlmatsum 'lnf' 'd11' = formula for \( \frac{\partial^2 \ln \ell_j}{\partial \theta_{1j}^2} \), eq(1) 
mlmatsum 'lnf' 'd12' = formula for \( \frac{\partial^2 \ln \ell_j}{\partial \theta_{1j} \partial \theta_{2j}} \), eq(1,2) 
mlmatsum 'lnf' 'd22' = formula for \( \frac{\partial^2 \ln \ell_j}{\partial \theta_{2j}^2} \), eq(2) ... 

matrix 'H' = ('d11','d12', \ldots \ 'd12','d22', \ldots ) 
end
where

\begin{itemize}
\item 'todo' contains 0 or 1
\item 'b' full parameter row vector \( b = (b_1, b_2, ..., b_E) \)
\item 'lnfj' scalar to be filled in with observation-by-observation \( \ln L \)
\item 'g1' variable to be filled in with \( \partial \ln\ell_j / \partial \theta_{1j} \)
\item 'g2' variable to be filled in with \( \partial \ln\ell_j / \partial \theta_{2j} \)
\item 'H' matrix to be filled in with overall Hessian \( H = \partial^2 \ln L / \partial b \partial b' \)
\end{itemize}

**Method-gf0 evaluators**

```plaintext
program proname
   version 14.2
   args todo b lnfj
   tempvar theta1 theta2 ...
   mleval 'theta1' = 'b', eq(1)
   mleval 'theta2' = 'b', eq(2) // if there is a \( \theta_2 \)
   ...
   // if you need to create any intermediate results:
   tempvar tmp1 tmp2 ...
   generate double 'tmp1' = ...
   ...
   quietly replace 'lnfj' = ...
end
```

where

\begin{itemize}
\item 'todo' always contains 0 (may be ignored)
\item 'b' full parameter row vector \( b = (b_1, b_2, ..., b_E) \)
\item 'lnfj' variable to be filled in with the values of the log-likelihood \( \ln \ell_j \)
\end{itemize}

**Global macros for use by all evaluators**

\begin{itemize}
\item $ML_y1$ name of first dependent variable
\item $ML_y2$ name of second dependent variable, if any
\item $ML_samp$ variable containing 1 if observation to be used; 0 otherwise
\item $ML_w$ variable containing weight associated with observation or 1 if no weights specified
\end{itemize}

Method-lf evaluators can ignore $ML_samp$, but restricting calculations to the \$ML_samp==1 subsample will speed execution. Method-lf evaluators must ignore $ML_w$; application of weights is handled by the method itself.

Methods d0, d1, d2, lf0, lf1, lf2, and gf0 can ignore $ML_samp$ as long as \texttt{ml model}'s nopreserve option is not specified. These methods will run more quickly if nopreserve is specified. These evaluators can ignore $ML_w$ only if they use \texttt{mlsum}, \texttt{mlvecsum}, \texttt{mlmatsum}, and \texttt{mlmatbysum} to produce all final results.
Options

Options are presented under the following headings:

- Options for use with `ml` model in interactive or noninteractive mode
- Options for use with `ml` model in noninteractive mode
- Options for use when specifying equations
- Options for use with `ml` search
- Option for use with `ml` plot
- Options for use with `ml` init
- Options for use with `ml` maximize
- Option for use with `ml` graph
- Options for use with `ml` display
- Options for use with `mleval`
- Option for use with `ml`eval
- Options for use with `ml` score
- Options for use with `ml` display
- Options for use with `mleval`
- Option for use with `ml`eval
- Options for use with `ml` vecsum
- Options for use with `ml` matsum
- Options for use with `ml` matbysum
- Options for use with `ml` score

Options for use with `ml` model in interactive or noninteractive mode

- `group(varname)` specifies the numeric variable that identifies groups. This option is typically used to identify panels for panel-data models.

- `vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that are derived from asymptotic theory (`oim`, `opg`); see [R] `vce_option`.

- `vce(robust)`, `vce(cluster clustvar)`, `pweight`, and `svy` will work with evaluators of methods `lf`, `lf0`, `lf1`, `lf2`, and `gf0`; all you need to do is specify them.

- These options will not work with evaluators of methods `d0`, `d1`, or `d2`, and specifying these options will produce an error message.

- `constraints(numlist | matname)` specifies the linear constraints to be applied during estimation.

- `constraints(numlist)` specifies the constraints by number. Constraints are defined by using the `constraint` command; see [R] `constraint`. `constraint(matname)` specifies a matrix that contains the constraints.

- `nocnsnotes` prevents notes from being displayed when constraints are dropped. A constraint will be dropped if it is inconsistent, contradicts other constraints, or causes some other error when the constraint matrix is being built. Constraints are checked in the order in which they are specified.

- `title(string)` specifies the title for the estimation output when results are complete.

- `nopreserve` specifies that `ml` need not ensure that only the estimation subsample is in memory when the user-written likelihood evaluator is called. `nopreserve` is irrelevant when you use method `lf`.

- For the other methods, if `nopreserve` is not specified, `ml` saves the data in a file (preserves the original dataset) and drops the irrelevant observations before calling the user-written evaluator. This way, even if the evaluator does not restrict its attentions to the $MLsamp==1$ subsample, results will still be correct. Later, `ml` automatically restores the original dataset.

- `ml` need not go through these machinations for method `lf` because the user-written evaluator calculates observation-by-observation values, and `ml` itself sums the components.

- `ml` goes through these machinations if and only if the estimation sample is a subsample of the data in memory. If the estimation sample includes every observation in memory, `ml` does not preserve the original dataset. Thus programmers must not alter the original dataset unless they `preserve` the data themselves.
We recommend that interactive users of \texttt{ml} not specify \texttt{nopreserve}; the speed gain is not worth the possibility of getting incorrect results.

We recommend that programmers specify \texttt{nopreserve}, but only after verifying that their evaluator really does restrict its attentions solely to the $\texttt{MLsamp==1}$ subsample.

collinear specifies that \texttt{ml} not remove the collinear variables within equations. There is no reason to leave collinear variables in place, but this option is of interest to programmers who, in their code, have already removed collinear variables and do not want \texttt{ml} to waste computer time checking again.

missing specifies that observations containing variables with missing values not be eliminated from the estimation sample. There are two reasons you might want to specify \texttt{missing}:

Programmers may wish to specify \texttt{missing} because, in other parts of their code, they have already eliminated observations with missing values and do not want \texttt{ml} to waste computer time looking again.

You may wish to specify \texttt{missing} if your model explicitly deals with missing values. Stata’s \texttt{heckman} command is a good example of this. In such cases, there will be observations where missing values are allowed and other observations where they are not—where their presence should cause the observation to be eliminated. If you specify \texttt{missing}, it is your responsibility to specify an if \texttt{exp} that eliminates the irrelevant observations.

\texttt{lf0(\#k, \#ll)} is typically used by programmers. It specifies the number of parameters and log-likelihood value of the constant-only model so that \texttt{ml} can report a likelihood-ratio test rather than a Wald test. These values may have been analytically determined, or they may have been determined by a previous fitting of the constant-only model on the estimation sample.

Also see the \texttt{continue} option directly below.

If you specify \texttt{lf0()}, it must be safe for you to specify the \texttt{missing} option, too, else how did you calculate the log likelihood for the constant-only model on the same sample? You must have identified the estimation sample, and done so correctly, so there is no reason for \texttt{ml} to waste time rechecking your results. All of which is to say, do not specify \texttt{lf0()} unless you are certain your code identifies the estimation sample correctly.

\texttt{lf0()}, even if specified, is ignored if \texttt{vce(robust)}, \texttt{vce(cluster clustvar)}, \texttt{pweight}, or \texttt{svy} is specified because, in that case, a likelihood-ratio test would be inappropriate.

\texttt{continue} is typically specified by programmers and does two things:

First, it specifies that a model has just been fit by either \texttt{ml} or some other estimation command, such as \texttt{logit}, and that the likelihood value stored in \texttt{e(ll)} and the number of parameters stored in \texttt{e(b)} as of that instant are the relevant values of the constant-only model. The current value of the log likelihood is used to present a likelihood-ratio test unless \texttt{vce(robust)}, \texttt{vce(cluster clustvar)}, \texttt{pweight}, \texttt{svy}, or \texttt{constraints()} is specified. A likelihood-ratio test is inappropriate when \texttt{vce(robust)}, \texttt{vce(cluster clustvar)}, \texttt{pweight}, or \texttt{svy} is specified. We suggest using \texttt{lrtest} when \texttt{constraints()} is specified; see [R] \texttt{lrtest}.

Second, \texttt{continue} sets the initial values, $b_0$, for the model about to be fit according to the \texttt{e(b)} currently stored.

The comments made about specifying \texttt{missing} with \texttt{lf0()} apply equally well here.

\texttt{waldtest(#)} is typically specified by programmers. By default, \texttt{ml} presents a Wald test, but that is overridden if the \texttt{lf0()} or \texttt{continue} option is specified. A Wald test is performed if \texttt{vce(robust)}, \texttt{vce(cluster clustvar)}, or \texttt{pweight} is specified.

\texttt{waldtest(0)} prevents even the Wald test from being reported.
waldtest(-1) is the default. It specifies that a Wald test be performed by constraining all coefficients except the intercept to 0 in the first equation. Remaining equations are to be unconstrained. A Wald test is performed if neither 1f0() nor continue was specified, and a Wald test is forced if vce(robust), vce(cluster clustvar), or pweight was specified.

waldtest(k) for \( k \leq -1 \) specifies that a Wald test be performed by constraining all coefficients except intercepts to 0 in the first \(|k|\) equations; remaining equations are to be unconstrained. A Wald test is performed if neither 1f0() nor continue was specified, and a Wald test is forced if vce(robust), vce(cluster clustvar), or pweight was specified.

waldtest(k) for \( k \geq 1 \) works like the options above, except that it forces a Wald test to be reported even if the information to perform the likelihood-ratio test is available and even if none of vce(robust), vce(cluster clustvar), or pweight was specified. waldtest(k), \( k \geq 1 \), may not be specified with 1f0().

obs(#) is used mostly by programmers. It specifies that the number of observations reported and ultimately stored in e(N) be #. Ordinarily, ml works that out for itself. Programmers may want to specify this option when, for the likelihood evaluator to work for \( N \) observations, they first had to modify the dataset so that it contained a different number of observations.

crittype(string) is used mostly by programmers. It allows programmers to supply a string (up to 32 characters long) that describes the criterion that is being optimized by ml. The default is "log likelihood" for nonrobust and "log pseudolikelihood" for robust estimation.

svy indicates that ml is to pick up the svy settings set by svyset and use the robust variance estimator. This option requires the data to be svyset; see [SVY] svyset. svy may not be specified with vce() or weights.

subpop(varname) specifies that estimates be computed for the single subpopulation defined by the observations for which varname \( \neq 0 \). Typically, varname = 1 defines the subpopulation, and varname = 0 indicates observations not belonging to the subpopulation. For observations whose subpopulation status is uncertain, varname should be set to missing (‘.’). This option requires the svy option.

nosvyadjust specifies that the model Wald test be carried out as \( W/k \sim F(k, d) \), where \( W \) is the Wald test statistic, \( k \) is the number of terms in the model excluding the constant term, \( d \) is the total number of sampled PSUs minus the total number of strata, and \( F(k, d) \) is an \( F \) distribution with \( k \) numerator degrees of freedom and \( d \) denominator degrees of freedom. By default, an adjusted Wald test is conducted: \( (d - k + 1)W/(kd) \sim F(k, d - k + 1) \). See Korn and Graubard (1990) for a discussion of the Wald test and the adjustments thereof. This option requires the svy option.

technique(algorithm_spec) specifies how the likelihood function is to be maximized. The following algorithms are currently implemented in ml. For details, see Gould, Pitblado, and Poi (2010).

- technique(nr) specifies Stata’s modified Newton–Raphson (NR) algorithm.
- technique(bhhh) specifies the Berndt–Hall–Hall–Hausman (BHHH) algorithm.
- technique(dfp) specifies the Davidon–Fletcher–Powell (DFP) algorithm.
- technique(bfgs) specifies the Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm.

The default is technique(nr).

You can switch between algorithms by specifying more than one in the technique() option. By default, ml will use an algorithm for five iterations before switching to the next algorithm. To specify a different number of iterations, include the number after the technique in the option. For example, technique(bhhh 10 nr 1000) requests that ml perform 10 iterations using the BHHH algorithm, followed by 1,000 iterations using the NR algorithm, and then switch back to BHHH for
10 iterations, and so on. The process continues until convergence or until reaching the maximum number of iterations.

**Options for use with ml model in noninteractive mode**

The following extra options are for use with `ml model` in noninteractive mode. Noninteractive mode is for programmers who use `ml` as a subroutine and want to issue one command that will carry forth the estimation from start to finish.

`maximize` is required. It specifies noninteractive mode.

`init(ml_init_args)` sets the initial values, $b_0$. `ml_init_args` are whatever you would type after the `ml init` command.

`search(on | norescale | quietly | off)` specifies whether `ml search` is to be used to improve the initial values. `search(on)` is the default and is equivalent to separately running `ml search`, `repeat(0)`. `search(norescale)` is equivalent to separately running `ml search`, `repeat(0) norescale`. `search(quietly)` is equivalent to `search(on)`, except that it suppresses `ml search`’s output. `search(off)` prevents calling `ml search`.

`repeat(#)` is `ml search`’s `repeat()` option. `repeat(0)` is the default.

`bounds(ml_search_bounds)` specifies the search bounds. `ml_search_bounds` is specified as

```
[ eqn_name ] lower_bound upper_bound ... [ eqn_name ] lower_bound upper_bound
```

for instance, `bounds(100 100 lnsigma 0 10)`. The `ml model` command issues `ml search ml_search_bounds, repeat(#)`.

Specifying search bounds is optional.

`nowarning`, `novce`, `negh`, and `score()` are `ml maximize`’s equivalent options.

`maximize_options:` `difficult`, `technique(algorithm_spec)`; `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] `maximize`. These options are seldom used.

**Options for use when specifying equations**

`noconstant` specifies that the equation not include an intercept.

`offset(varname_o)` specifies that the equation be $xb + varname_o$—that it include $varname_o$ with coefficient constrained to be 1.

`exposure(varname_e)` is an alternative to `offset(varname_o)`; it specifies that the equation be $xb + \ln(varname_e)$. The equation is to include $\ln(varname_e)$ with coefficient constrained to be 1.

**Options for use with ml search**

`repeat(#)` specifies the number of random attempts that are to be made to find a better initial-value vector. The default is `repeat(10)`.

`repeat(0)` specifies that no random attempts be made. More precisely, `repeat(0)` specifies that no random attempts be made if the first initial-value vector is a feasible starting point. If it is not, `ml search` will make random attempts, even if you specify `repeat(0)`, because it has no alternative. The `repeat()` option refers to the number of random attempts to be made to improve the initial values. When the initial starting value vector is not feasible, `ml search` will make up to 1,000 random attempts to find starting values. It stops when it finds one set of values that works and then moves into its improve-initial-values logic.
repeat\((k)\), \(k > 0\), specifies the number of random attempts to be made to improve the initial values.

\texttt{restart} specifies that random actions be taken to obtain starting values and that the resulting starting values not be a deterministic function of the current values. Generally, you should not specify this option because, with \texttt{restart}, \texttt{ml search} intentionally does not produce as good a set of starting values as it could. \texttt{restart} is included for use by the optimizer when it gets into serious trouble. The random actions ensure that the optimizer and \texttt{ml search}, working together, do not cause an endless loop.

\texttt{restart} implies \texttt{norescale}, which is why we recommend that you do not specify \texttt{restart}. In testing, sometimes \texttt{rescale} worked so well that, even after randomization, the rescaler would bring the starting values right back to where they had been the first time and thus defeat the intended randomization.

\texttt{norescale} specifies that \texttt{ml search} not engage in its rescaling actions to improve the parameter vector. We do not recommend specifying this option because rescaling tends to work so well.

\texttt{maximize\_options}: \texttt{[no]log} and \texttt{trace}; see \texttt{[R] maximize}. These options are seldom used.

\textbf{Option for use with ml plot}

\texttt{saving(filename[, replace])} specifies that the graph be saved in \texttt{filename.gph}.

See \texttt{[G-3] saving\_option}.

\textbf{Options for use with ml init}

\texttt{copy} specifies that the list of numbers or the initialization vector be copied into the initial-value vector by position rather than by name.

\texttt{skip} specifies that any parameters found in the specified initialization vector that are not also found in the model be ignored. The default action is to issue an error message.

\textbf{Options for use with ml maximize}

\texttt{nowarning} is allowed only with \texttt{iterate(0)}. \texttt{nowarning} suppresses the “convergence not achieved” message. Programmers might specify \texttt{iterate(0) nowarning} when they have a vector \texttt{b} already containing the final estimates and want \texttt{ml} to calculate the variance matrix and postestimation results. Then specify \texttt{init(b) search(off) iterate(0) nowarning nolog}.

\texttt{novce} is allowed only with \texttt{iterate(0)}. \texttt{novce} substitutes the zero matrix for the variance matrix, which in effect posts estimation results as fixed constants.

\texttt{negh} indicates that the evaluator returns the negative Hessian matrix. By default, \texttt{ml} assumes \texttt{d2} and \texttt{lf2} evaluators return the Hessian matrix.

\texttt{score(newvars|stub*)} creates new variables containing the contributions to the score for each equation and ancillary parameter in the model; see \texttt{[U] 20.22 Obtaining scores}.

If \texttt{score(newvars)} is specified, the \texttt{newvars} must contain \(k\) new variables. For evaluators of methods \texttt{lf, lf0, lf1}, and \texttt{lf2}, \(k\) is the number of equations. For evaluators of method \texttt{gf0}, \(k\) is the number of parameters. If \texttt{score(stub*)} is specified, variables named \texttt{stub1, stub2, \ldots, stubk} are created.

For evaluators of methods \texttt{lf, lf0, lf1}, and \texttt{lf2}, the first variable contains \(\partial \ln \ell_j / \partial (x_{1j} b_1)\), the second variable contains \(\partial \ln \ell_j / \partial (x_{2j} b_2)\), and so on.
For evaluators of method gf0, the first variable contains \( \partial \ln \ell_j / \partial b_1 \), the second variable contains \( \partial \ln \ell_j / \partial b_2 \), and so on.

`nooutput` suppresses display of results. This option is different from prefixing `ml maximize` with `quietly` in that the iteration log is still displayed (assuming that `nolog` is not specified).

`noclear` specifies that the `ml` problem definition not be cleared after the model has converged. Perhaps you are having convergence problems and intend to run the model to convergence. If so, use `ml search` to see if those values can be improved, and then restart the estimation.

`maximize_options`: `difficult, iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance`; see `[R] maximize`. These options are seldom used.

`display_options`: see Options for use with `ml display` below.

`eform_option`: see Options for use with `ml display` below.

**Option for use with `ml graph`**

`saving(filename[, replace])` specifies that the graph be saved in `filename.gph`.

**Options for use with `ml display`**

`noheader` suppresses the header display above the coefficient table that displays the final log-likelihood value, the number of observations, and the model significance test.

`nofootnote` suppresses the footnote display below the coefficient table, which displays a warning if the model fit did not converge within the specified number of iterations. Use `ml footnote` to display the warning if 1) you add to the coefficient table using the `plus` option or 2) you have your own footnotes and want the warning to be last.

`level(#)` is the standard confidence-level option. It specifies the confidence level, as a percentage, for confidence intervals of the coefficients. The default is `level(95)` or as set by `set level`; see `[U] 20.7 Specifying the width of confidence intervals`.

`first` displays a coefficient table reporting results for the first equation only, and the report makes it appear that the first equation is the only equation. This option is used by programmers who estimate ancillary parameters in the second and subsequent equations and who wish to report the values of such parameters themselves.

`neq(#)` is an alternative to `first`. `neq(#)` displays a coefficient table reporting results for the first # equations. This option is used by programmers who estimate ancillary parameters in the # + 1 and subsequent equations and who wish to report the values of such parameters themselves.

`showeqns` is a seldom-used option that displays the equation names in the coefficient table. `ml display` uses the numbers stored in `e(k_eq)` and `e(k_aux)` to determine how to display the coefficient table. `e(k_eq)` identifies the number of equations, and `e(k_aux)` identifies how many of these are for ancillary parameters. The `first` option is implied when `showeqns` is not specified and all but the first equation are for ancillary parameters.

`plus` displays the coefficient table, but rather than ending the table in a line of dashes, ends it in dashes–plus-sign–dashes. This is so that programmers can write additional display code to add more results to the table and make it appear as if the combined result is one table. Programmers typically specify `plus` with the `first` or `neq()` options. This option implies `nofootnote`. 
nocnsreport suppresses the display of constraints above the coefficient table. This option is ignored if constraints were not used to fit the model.

noomitted specifies that variables that were omitted because of collinearity not be displayed. The default is to include in the table any variables omitted because of collinearity and to label them as “(omitted)”.

vsquish specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.

noemptycells specifies that empty cells for interactions of factor variables not be displayed. The default is to include in the table interaction cells that do not occur in the estimation sample and to label them as “(empty)”.

baselevels and allbaselevels control whether the base levels of factor variables and interactions are displayed. The default is to exclude from the table all base categories.

baselevels specifies that base levels be reported for factor variables and for interactions whose bases cannot be inferred from their component factor variables.

allbaselevels specifies that all base levels of factor variables and interactions be reported.

cformat(%) fmt specifies how to format coefficients, standard errors, and confidence limits in the coefficient table.

pformat(%) fmt specifies how to format p-values in the coefficient table.

sformat(%) fmt specifies how to format test statistics in the coefficient table.

nolstretch specifies that the width of the coefficient table not be automatically widened to accommodate longer variable names. The default, lstretch, is to automatically widen the coefficient table up to the width of the Results window. To change the default, use set lstretch off. nolstretch is not shown in the dialog box.

coeflegend specifies that the legend of the coefficients and how to specify them in an expression be displayed rather than displaying the statistics for the coefficients.

\textit{eform} \texttt{option}: eform(string), eform, hr, shr, irr, or, and rrr display the coefficient table in exponentiated form: for each coefficient, \( \exp(b) \) rather than \( b \) is displayed, and standard errors and confidence intervals are transformed. \textit{string} is the table header that will be displayed above the transformed coefficients and must be 11 characters or shorter in length—for example, eform("Odds ratio"). The options eform, hr, shr, irr, or, and rrr provide a default \textit{string} equivalent to “exp(b)”, “Haz. Ratio”, “SHR”, “IRR”, “Odds Ratio”, and “RRR”, respectively. These options may not be combined.

\texttt{ml display} looks at \texttt{e(k_eform)} to determine how many equations are affected by an \textit{eform} \texttt{option}; by default, only the first equation is affected. Type \texttt{ereturn list, all} to view \texttt{e(k_eform)}; see [P] \texttt{ereturn}.

**Options for use with mleval**

\texttt{eq(\#)} specifies the equation number, \( i \), for which \( \theta_{ij} = x_{ij}b_i \) is to be evaluated. \texttt{eq(1)} is assumed if \texttt{eq(\#)} is not specified.

\texttt{scalar} asserts that the \( i \)th equation is known to evaluate to a constant, meaning that the equation was specified as \( () \), \( (\text{name}::) \), or \( /\text{name} \) on the \texttt{ml model} statement. If you specify this option, the new variable created is created as a scalar. If the \( i \)th equation does not evaluate to a scalar, an error message is issued.
Option for use with mlsum

noweight specifies that weights ($ML_w$) be ignored when summing the likelihood function.

Option for use with mlvecsum

\texttt{eq(#)} specifies the equation for which a gradient vector $\partial \ln L/\partial b_i$ is to be constructed. The default is $\texttt{eq(1)}$.

Option for use with mlmatsum

\texttt{eq[#[,#]]} specifies the equations for which the Hessian matrix is to be constructed. The default is $\texttt{eq(1)}$, which is the same as $\texttt{eq(1,1)}$, which means $\partial^2 \ln L/\partial b_1 \partial b_1'$. Specifying $\texttt{eq(i,j)}$ results in $\partial^2 \ln L/\partial b_i \partial b_j'$.

Options for use with mlmatbysum

\texttt{by(varname)} is required and specifies the group variable.

\texttt{eq[#[,#]]} specifies the equations for which the Hessian matrix is to be constructed. The default is $\texttt{eq(1)}$, which is the same as $\texttt{eq(1,1)}$, which means $\partial^2 \ln L/\partial b_1 \partial b_1'$. Specifying $\texttt{eq(i,j)}$ results in $\partial^2 \ln L/\partial b_i \partial b_j'$.

Options for use with ml score

\texttt{equation(eqname)} identifies from which equation the observation scores are to come. This option may be used only when generating one variable.

\texttt{missing} specifies that observations containing variables with missing values not be eliminated from the estimation sample.

Remarks and examples

For a thorough discussion of \texttt{ml}, see the fourth edition of \textit{Maximum Likelihood Estimation with Stata} (Gould, Pitblado, and Poi 2010). The book provides a tutorial introduction to \texttt{ml}, notes on advanced programming issues, and a discourse on maximum likelihood estimation from both theoretical and practical standpoints. See \textit{Survey options and ml} at the end of \textit{Remarks and examples} for examples of the new \texttt{svy} options. For more information about survey estimation, see \texttt{[SVY] survey}, \texttt{[SVY] svy estimation}, and \texttt{[SVY] variance estimation}.

\texttt{ml} requires that you write a program that evaluates the log-likelihood function and, possibly, its first and second derivatives. The style of the program you write depends upon the method you choose. Methods \texttt{lf}, \texttt{lf0}, \texttt{d0}, and \texttt{gf0} require that your program evaluate the log likelihood only. Methods \texttt{d1} and \texttt{lf1} require that your program evaluate the log likelihood and its first derivatives. Methods \texttt{d2} and \texttt{lf2} requires that your program evaluate the log likelihood and its first and second derivatives. Methods \texttt{lf}, \texttt{lf0}, \texttt{d0}, and \texttt{gf0} differ each other in that, with methods \texttt{lf} and \texttt{lf0}, your program is required to produce observation-by-observation log-likelihood values $\ln \ell_j$, and it is assumed that $\ln L = \sum_{j} \ln \ell_j$; with method \texttt{d0}, your program is required to produce only the overall value $\ln L$; and with method \texttt{gf0}, your program is required to produce the summable pieces of the log likelihood, such as those in panel-data models.
Once you have written the program—called an evaluator—you define a model to be fit using ml model and obtain estimates using ml maximize. You might type

```
.ml model ...
.ml maximize
```

but we recommend that you type

```
.ml model ...
.ml check
.ml search
.ml maximize
```

ml check verifies your evaluator has no obvious errors, and ml search finds better initial values.

You fill in the ml model statement with 1) the method you are using, 2) the name of your program, and 3) the “equations”. You write your evaluator in terms of $\theta_1$, $\theta_2$, ..., each of which has a linear equation associated with it. That linear equation might be as simple as $\theta_i = b_0$, it might be $\theta_i = b_1 \text{mpg} + b_2 \text{weight} + b_3$, or it might omit the intercept $b_3$. The equations are specified in parentheses on the ml model line.

Suppose that you are using method lf and the name of your evaluator program is myprog. The statement

```
.ml model lf myprog (mpg weight)
```

would specify one equation with $\theta_i = b_1 \text{mpg} + b_2 \text{weight} + b_3$. If you wanted to omit $b_3$, you would type

```
.ml model lf myprog (mpg weight, nocons)
```

and if all you wanted was $\theta_i = b_0$, you would type

```
.ml model lf myprog ()
```

With multiple equations, you list the equations one after the other; so, if you typed

```
.ml model lf myprog (mpg weight) ()
```

you would be specifying $\theta_1 = b_1 \text{mpg} + b_2 \text{weight} + b_3$ and $\theta_2 = b_4$. You would write your likelihood in terms of $\theta_1$ and $\theta_2$. If the model was linear regression, $\theta_1$ might be the $\text{xb}$ part and $\theta_2$ the variance of the residuals.

When you specify the equations, you also specify any dependent variables. If you typed

```
.ml model lf myprog (price = mpg weight) ()
```

price would be the one and only dependent variable, and that would be passed to your program in $\$ML_y1$. If your model had two dependent variables, you could type

```
.ml model lf myprog (price displ = mpg weight) ()
```

Then $\$ML_y1$ would be price and $\$ML_y2$ would be displ. You can specify however many dependent variables are necessary and specify them on any equation. It does not matter on which equation you specify them; the first one specified is placed in $\$ML_y1$, the second in $\$ML_y2$, and so on.
Example 1: Method lf

Using method lf, we want to produce observation-by-observation values of the log likelihood. The probit log-likelihood function is

\[ \ln \ell_j = \begin{cases} 
\ln \Phi(\theta_{1j}) & \text{if } y_j = 1 \\
\ln \Phi(-\theta_{1j}) & \text{if } y_j = 0 
\end{cases} \] 

[\theta_{1j} = x_j b_1]

The following is the method-lf evaluator for this likelihood function:

```
program myprobit
    version 14.2
    args lnf theta1
    quietly replace `lnf' = ln(normal(`theta1')) if $ML_y1==1
    quietly replace `lnf' = ln(normal(-`theta1')) if $ML_y1==0
end
```

If we wanted to fit a model of foreign on mpg and weight, we would type the following commands. The `foreign =` part specifies that \( y \) is foreign. The `mpg weight` part specifies that \( \theta_{1j} = b_1 \text{mpg}_j + b_2 \text{weight}_j + b_3 \).

```
use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
.ml model lf myprobit (foreign = mpg weight)
.ml maximize
```

```
Number of obs = 74
Wald chi2(2) = 20.75
Log likelihood = -26.844189

| foreign  | Coef.   | Std. Err. | z    | P>|z|    | [95% Conf. Interval] |
|----------|---------|-----------|------|--------|----------------------|
| mpg      | -0.1039503 | 0.0515689 | -2.02 | 0.044  | -0.2050235 to -0.0028772 |
| weight   | -0.0023355  | 0.0005661 | -4.13 | 0.000  | -0.003445 to -0.0012261 |
| _cons    | 8.275464    | 2.554142  | 3.24 | 0.001  | 3.269438 to 13.28149 |
```

Example 2: Method lf for two-equation, two-dependent-variable model

A two-equation, two-dependent-variable model is a little different. Rather than receiving one \( \theta \), our program will receive two. Rather than there being one dependent variable in $ML\_y1$, there will be dependent variables in $ML\_y1$ and $ML\_y2$. For instance, the Weibull regression log-likelihood function is
\[
\ln \ell_j = -(t_j e^{-\theta_{1j}}) \exp(\theta_{2j}) + d_j \{ \theta_{2j} - \theta_{1j} + (e^{\theta_{2j}} - 1)(\ln t_j - \theta_{1j}) \}
\]

\[
\theta_{1j} = x_j b_1
\]

\[
\theta_{2j} = s
\]

where \( t_j \) is the time of failure or censoring and \( d_j = 1 \) if failure and 0 if censored. We can make the log likelihood a little easier to program by introducing some extra variables:

\[
\begin{align*}
  p_j &= \exp(\theta_{2j}) \\
  M_j &= \{ t_j \exp(-\theta_{1j}) \}^{p_j} \\
  R_j &= \ln t_j - \theta_{1j} \\
  \ln \ell_j &= -M_j + d_j \{ \theta_{2j} - \theta_{1j} + (p_j - 1)R_j \}
\end{align*}
\]

The method-lf evaluator for this is

```stata
program myweib
    version 14.2
    args lnf theta1 theta2
    tempvar p M R
    quietly generate double 'p' = exp('theta2')
    quietly generate double 'M' = ($ML_y1*exp(-'theta1'))^'p'
    quietly generate double 'R' = ln($ML_y1)-'theta1'
    quietly replace 'lnf' = -'M' + $ML_y2*('theta2'-'theta1' + ('p'-1)*'R')
end
```

We can fit a model by typing

```
. ml model lf myweib (studytime died = i.drug age) ()
. ml maximize
```

Note that we specified ‘()’ for the second equation. The second equation corresponds to the Weibull shape parameter \( s \), and the linear combination we want for \( s \) contains just an intercept. Alternatively, we could type

```
. ml model lf myweib (studytime died = i.drug age) /s
```

Typing /s means the same thing as typing (s:), and both really mean the same thing as (). The \( s \), either after a slash or in parentheses before a colon, labels the equation. It makes the output look prettier, and that is all:
```
. use http://www.stata-press.com/data/r14/cancer, clear
(Patient Survival in Drug Trial)
. ml model lf myweib (studytime died = i.drug age) /s
. ml maximize
initial: log likelihood = -744

```

Example 3: Method d0

Method-d0 evaluators receive \( b = (b_1, b_2, \ldots, b_E) \), the coefficient vector, rather than the already evaluated \( \theta_1, \theta_2, \ldots, \theta_E \), and they are required to evaluate the overall log-likelihood \( \ln L \) rather than \( \ln \ell_j, j = 1, \ldots, N \).

Use `mleval` to produce the thetas from the coefficient vector.

Use `mlsum` to sum the components that enter into \( \ln L \).
In the case of Weibull, \( \ln L = \sum \ln \ell_j \), and our method-d0 evaluator is

```
program weib0
    version 14.2
    args todo b lnf
    tempvar theta1 theta2
    mleval `theta1' = `b', eq(1)
    mleval `theta2' = `b', eq(2)
    local t "$ML_y1" // this is just for readability
    local d "$ML_y2"
    tempvar p M R
    quietly generate double `p' = exp(`theta2')
    quietly generate double `M' = (`t'*exp(-`theta1'))^`p'
    quietly generate double `R' = ln(`t')-`theta1'
    mlsum `lnf' = -`M' + `d'*(`theta2'-'theta1' + (`p'-1)'R')
end
```

To fit our model using this evaluator, we would type

```
. ml model d0 weib0 (studytime died = i.drug age) /s
. ml maximize
```

### Technical note

Method d0 does not require \( \ln L = \sum_j \ln \ell_j, j = 1, \ldots, N \), as method lf does. Your likelihood function might have independent components only for groups of observations. Panel-data estimators have a log-likelihood value \( \ln L = \sum_i \ln L_i \), where \( i \) indexes the panels, each of which contains multiple observations. Conditional logistic regression has \( \ln L = \sum_k \ln L_k \), where \( k \) indexes the risk pools. Cox regression has \( \ln L = \sum_{(t)} \ln L_{(t)} \), where \( (t) \) denotes the ordered failure times.

To evaluate such likelihood functions, first calculate the within-group log-likelihood contributions. This usually involves `generate` and `replace` statements prefixed with by, as in

```
tempvar sumd
    by group: generate double `sumd' = sum($ML_y1)
```

Structure your code so that the log-likelihood contributions are recorded in the last observation of each group. Say that a variable is named `cont'. To sum the contributions, code

```
tempvar last
    quietly by group: generate byte `last' = (_n==_N)
    mlsum `lnf' = `cont' if `last'
```

You must inform `mlsum` which observations contain log-likelihood values to be summed. First, you do not want to include intermediate results in the sum. Second, `mlsum` does not skip missing values. Rather, if `mlsum` sees a missing value among the contributions, it sets the overall result, `lnf', to missing. That is how `ml maximize` is informed that the likelihood function could not be evaluated at the particular value of \( b \). `ml maximize` will then take action to escape from what it thinks is an infeasible area of the likelihood function.

When the likelihood function violates the linear-form restriction \( \ln L = \sum_j \ln \ell_j, j = 1, \ldots, N \), with \( \ln \ell_j \) being a function solely of values within the \( j \)th observation, use method d0. In the following examples, we will demonstrate methods d1 and d2 with likelihood functions that meet this linear-form restriction. The d1 and d2 methods themselves do not require the linear-form restriction, but the utility routines `mlvecsum` and `mlmatsum` do. Using method d1 or d2 when the restriction is violated is difficult; however, `mlmatbysum` may be of some help for method-d2 evaluators.
Example 4: Method d1

Method-d1 evaluators are required to produce the gradient vector \( g = \partial \ln L / \partial b \), as well as the overall log-likelihood value. Using \( \text{mlvecsum} \), we can obtain \( \partial \ln L / \partial \theta_i \), \( i = 1, \ldots, E \). The derivatives of the Weibull log-likelihood function are

\[
\frac{\partial \ln \ell_j}{\partial \theta_{1j}} = p_j (M_j - d_j) \\
\frac{\partial \ln \ell_j}{\partial \theta_{2j}} = d_j - R_j p_j (M_j - d_j)
\]

The method-d1 evaluator for this is

```plaintext
program weib1
    version 14.2
    args todo b lnf g // g is new
    tempvar t1 t2
    mleval 't1' = 'b', eq(1)
    mleval 't2' = 'b', eq(2)
    local t "$ML_y1"
    local d "$ML_y2"
    tempvar p M R
    quietly generate double 'p' = exp('t2')
    quietly generate double 'M' = ('t'*exp(-'t1'))^'p'
    quietly generate double 'R' = ln('t')-'t1'
    mlsum 'lnf' = -'M' + 'd'*(-'t2'+'t1' + ('p'-1)*'R')
    if ('todo'==0 | 'lnf'>=.) exit /* <-- new */
    tempname d1 d2 /* <-- new */
    mlvecsum 'lnf' 'd1' = 'p'*('M'-'d'), eq(1) /* <-- new */
    mlvecsum 'lnf' 'd2' = 'd' - 'R'+'p'*(('M'-'d'), eq(2) /* <-- new */
    matrix 'g' = ('d1','d2') /* <-- new */
end
```

We obtained this code by starting with our method-d0 evaluator and then adding the extra lines that method d1 requires. To fit our model using this evaluator, we could type

```
. ml model d1 weib1 (studytime died = drug2 drug3 age) /s
. ml maximize
```

but we recommend substituting method d1debug for method d1 and typing

```
. ml model d1debug weib1 (studytime died = drug2 drug3 age) /s
. ml maximize
```

Method d1debug will compare the derivatives we calculate with numerical derivatives and thus verify that our program is correct. Once we are certain the program is correct, then we would switch from method d1debug to method d1.

Example 5: Method d2

Method-d2 evaluators are required to produce \( H = \partial^2 \ln L / \partial b \partial b' \), the Hessian matrix, as well as the gradient and log-likelihood value. \( \text{mlmatsum} \) will help calculate \( \partial^2 \ln L / \partial b \partial b' \) from the second derivatives with respect to \( \theta \). For the Weibull model, these second derivatives are
\[
\frac{\partial^2 \ln \ell_j}{\partial \theta_{1j}^2} = -p_j^2 M_j
\]
\[
\frac{\partial^2 \ln \ell_j}{\partial \theta_{1j} \partial \theta_{2j}} = p_j (M_j - d_j + R_j p_j M_j)
\]
\[
\frac{\partial^2 \ln \ell_j}{\partial \theta_{2j}^2} = -p_j R_j (R_j p_j M_j + M_j - d_j)
\]

The method-d2 evaluator is

```
program weib2
    version 14.2
    args todo b lnf g H       // H added
    tempvar t1 t2
    mleval 't1' = 'b', eq(1)
    mleval 't2' = 'b', eq(2)
    local t "$ML_y1"
    local d "$ML_y2"
    tempvar p M R
    quietly generate double 'p' = exp('t2')
    quietly generate double 'M' = ('t'*exp(-'t1'))*'p'
    quietly generate double 'R' = ln('t')-'t1'
    mlsum 'lnf' = -'M' + 'd'$('t2'-'t1' + ('p'-1)*'R')
    if ('todo'==0 | 'lnf'>=.) exit
    tempname d1 d2
    mlvecsum 'lnf' 'd1' = 'p'*('M'-'d'), eq(1)
    mlvecsum 'lnf' 'd2' = 'd' - 'R'*$'p'$('M'-'d'), eq(2)
    matrix 'g' = ('d1','d2')
    if ('todo'==1 | 'lnf'>=.) exit // new from here down
    tempname d11 d12 d22
    mlmatsum 'lnf' 'd11' = -'p'^2 * 'M', eq(1)
    mlmatsum 'lnf' 'd12' = 'p'$('M'-'d' + 'R'*$'p'$('M'-'d')), eq(1,2)
    mlmatsum 'lnf' 'd22' = -'p'*$'R'$('R'*$'p'$('M' + 'M' - 'd'), eq(2)
    matrix 'H' = ('d11','d12' \ 'd12','d22')
end
```

We started with our previous method-d1 evaluator and added the lines that method d2 requires. We could now fit a model by typing

```
. ml model d2 weib2 (studytime died = drug2 drug3 age) /s
. ml maximize
```

but we would recommend substituting method d2debug for method d2 and typing

```
. ml model d2debug weib2 (studytime died = drug2 drug3 age) /s
. ml maximize
```

Method d2debug will compare the first and second derivatives we calculate with numerical derivatives and thus verify that our program is correct. Once we are certain the program is correct, then we would switch from method d2debug to method d2.

As we stated earlier, to produce the robust variance estimator with method lf, there is nothing to do except specify `vce(robust)`, `vce(cluster clustvar)`, or `pweight`. For methods d0, d1, and d2, these options do not work. If your likelihood function meets the linear-form restrictions, you can use methods lf0, lf1, and lf2, then these options will work. The equation scores are defined as

\[
\frac{\partial \ln \ell_j}{\partial \theta_{1j}}, \frac{\partial \ln \ell_j}{\partial \theta_{2j}}, \ldots
\]
Your evaluator will be passed variables, one for each equation, which you fill in with the equation scores. For both method lf1 and lf2, these variables are passed in the fourth and subsequent positions of the argument list. That is, you must process the arguments as

    args todo b lnf g1 g2 ... H

Note that for method lf1, the ‘H’ argument is not used and can be ignored.

> Example 6: Robust variance estimates

If you have used mlvecsum in your evaluator of method d1 or d2, it is easy to turn it into evaluator of method lf1 or lf2 that allows the computation of the robust variance estimator. The expression that you specified on the right-hand side of mlvecsum is the equation score.

Here we turn the program that we gave earlier in the method-d1 example into a method-lf1 evaluator that allows vce(robust), vce(cluster clustvar), or pweight.

    program weib1
    version 14.2
    args todo b lnfj g1 g2 // g1 and g2 are new
    tempvar t1 t2
    mleval 't1' = 'b', eq(1)
    mleval 't2' = 'b', eq(2)
    local t "$ML_y1"
    local d "$ML_y2"
    tempvar p M R
    quietly generate double 'p' = exp('t2')
    quietly generate double 'M' = ('t'*exp(-'t1'))^'p'
    quietly generate double 'R' = ln('t')-'t1'
    quietly replace 'lnfj' = -'M' + 'd'*( 't2'-'t1' + ('p'-1)*'R')
    if ('todo'==0) exit
    quietly replace 'g1' = 'p'*('M'-'d') /* <-- new */
    quietly replace 'g2' = 'd' - 'R'*'p'*( 'M'-'d') /* <-- new */
    end

To fit our model and get the robust variance estimates, we type

    . ml model lf1 weib1 (studytime died = drug2 drug3 age) /s, vce(robust)
    . ml maximize

Survey options and ml

    ml can handle stratification, poststratification, multiple stages of clustering, and finite population corrections. Specifying the svy option implies that the data come from a survey design and also implies that the survey linearized variance estimator is to be used; see [SVY] variance estimation.

> Example 7

Suppose that we are interested in a probit analysis of data from a survey in which q1 is the answer to a yes/no question and x1, x2, x3 are demographic responses. The following is a lf2 evaluator for the probit model that meets the requirements for vce(robust) (linear form and computes the scores).
To fit a model, we `svyset` the data, then use `svy` with `ml`.

```
. svyset psuid [pw=w], strata(strid)
. ml model lf2 mylf2probit (q1 = x1 x2 x3), svy
. ml maximize
```

We could also use the `subpop()` option to make inferences about the subpopulation identified by the variable `sub`:

```
. svyset psuid [pw=w], strata(strid)
. ml model lf2 mylf2probit (q1 = x1 x2 x3), svy subpop(sub)
. ml maximize
```

## Stored results

For results stored by `ml` without the `svy` option, see [R] `maximize`.

For results stored by `ml` with the `svy` option, see [SVY] `svy`.

## Methods and formulas

`ml` is implemented using `moptimize()`; see [M-5] `moptimize()`.

### Description

`mlexp` performs maximum likelihood estimation of models that satisfy the linear-form restrictions, that is, models for which you can write the log likelihood for an individual observation and for which the overall log likelihood is the sum of the individual observations’ log likelihoods.

You express the observation-level log-likelihood function by using a substitutable expression. Unlike models fit using `ml`, you do not need to do any programming. However, `ml` can fit classes of models that cannot be fit by `mlexp`.

### Quick start

**Linear regression of $y$ on $x_1$ and $x_2$**

```stata
mlexp (ln(normalden(y, {xb: x1 x2 _cons}, {sigma})))
```

Same as above

```stata
mlexp (ln(normalden(y, {b0} + {b1}*x1 + {b2}*x2, {sigma})))
```

As above, and set initial values for $b_2$ and $\sigma$

```stata
mlexp (ln(normalden(y, {b0} + {b1}*x1 + {b2=0.5}*x2, {sigma=3})))
```

Constrain $\sigma$ and the coefficient on $x_1$ to be positive

```stata
mlexp (ln(normalden(y, {b0} + exp({lnb1})*x1 + {b2}*x2, exp({lnsigma}))))
nlcom (b1: exp(_b[lnb1:_cons])) (sigma: exp(_b[lnsigma:_cons]))
```

Omit observations with missing values for $y$, $x_1$, or $x_2$

```stata
mlexp (ln(normalden(y, {xb: x1 x2 _cons}, {sigma}))), variables(y x1 x2)
```

\( \text{lexp} \) and \( \text{dexp} \) may contain factor variables and time-series operators; see [U] 11.4.3 Factor variables and [U] 11.4.4 Time-series varlists.

bootstrap, by, jackknife, rolling, statsby, and \text{svy} are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

aweight

aweights are not allowed with the jackknife prefix; see [R] jackknife.

aweights, fweight, iweight, and pweight are allowed; see [U] 11.1.6 weight.

debug and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

\( \text{lexp} \) and \( \text{dexp} \) are substitutable expressions, Stata expressions that also contain parameters to be estimated. The parameters are enclosed in curly braces and must satisfy the naming requirements for variables; \{\text{beta}\} is an example of a parameter. The notation \{\text{lc:varlist}\} is allowed for linear combinations of multiple covariates and their parameters. For example, \{\text{xb: mp} \text{g} \text{price turn cons}\} defines a linear combination of the variables \text{mpg}, \text{price}, \text{turn}, and \text{cons} (the constant term). See Substitutable expressions under Remarks and examples below.
Models

variables(varlist) specifies the variables in the model. mlexp excludes observations for which any of these variables has missing values. If you do not specify variables(), then mlexp assumes all observations are valid. mlexp will exit with an error message if the log likelihood cannot be calculated at the initial values for any observation.

from(initial_values) specifies the initial values to begin the estimation. You can specify parameter names and values, or you can specify a $1 \times k$ matrix, where $k$ is the number of parameters in the model. For example, to initialize alpha to 1.23 and delta to 4.57, you would type

```
mlexp ..., from(alpha=1.23 delta=4.57) ...
```

or equivalently

```
matrix define initval = (1.23, 4.57)
mlexp ..., from(initval) ...
```

Initial values declared in the from() option override any that are declared within substitutable expressions. If you specify a parameter that does not appear in your model, mlexp exits with an error. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model.

constraints(numlist), collinear; see [R] estimation options.

Derivatives

derivative(/name = dexp) specifies the derivative of the observation-level log-likelihood function with respect to parameter name. If you wish to specify analytic derivatives, you must specify derivative() for each parameter in your model.

dexp uses the same substitutable expression syntax as is used to specify the log-likelihood function. If you declare a linear combination in the log-likelihood function, you provide the derivative for the linear combination; mlexp then applies the chain rule for you. See Specifying derivatives under Remarks and examples for examples.

If you do not specify the derivative() option, mlexp calculates derivatives numerically.

SE/Robust

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

Reporting

level(#); see [R] estimation options.

title(string) specifies an optional title that will be displayed just above the table of parameter estimates.

title2(string) specifies an optional subtitle that will be displayed between the title specified in title() and the table of parameter estimates. If title2() is specified but title() is not, then title2() has the same effect as title().

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels,nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] estimation options.
mlexp — Maximum likelihood estimation of user-specified expressions

Maximization

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace,
gradient, showstep, hessian, showtolltolerance, tollerance(#),
ntolernance(#), and nonrtolernance; see [R] maximize. These options are seldom used.

The following options are available with mlexp but are not shown in the dialog box:

difficult specifies that differences between the numerically computed gradient and the gradient computed from your derivative expression are reported at each iteration. This option is only allowed with the derivative() option.

coefflegend; see [R] estimation options.

Remarks and examples

Remarks are presented under the following headings:

Introduction
Substitutable expressions
Parameter interpretation using margins
Parameter constraints
Specifying derivatives

Introduction

mlexp performs maximum likelihood estimation of models that satisfy the linear-form restrictions, that is, models for which you can write the log likelihood for a single observation and for which the overall log likelihood is the sum of the individual observations’ log likelihoods. Models designed for use with cross-sectional data usually meet the linear-form restrictions, including linear regression, many discrete-choice models, limited-dependent-variable models, and selection models. Examples of models that do not satisfy the linear-form restrictions are random-effects panel-data models (because the likelihood function is defined at the panel level) and Cox proportional hazards models (because the likelihood function is defined for risk sets).

Because of its straightforward syntax and accessibility from the menu system, mlexp is particularly suited to users who are new to Stata and to those using Stata for pedagogical purposes. You specify the log-likelihood function that mlexp is to maximize by using substitutable expressions that are similar to those used by nl, nlsur, and gmm. mlexp allows you to avoid the programming requirements of ml. However, ml can fit classes of models that cannot be fit by mlexp, including those that do not meet the linear-form restrictions.

Substitutable expressions

Substitutable expressions allow you to distinguish between variables and parameters. There are three rules to follow when defining substitutable expressions:

1. Parameters of the model are bound in curly braces: \{b0\}, \{param\}, etc. Parameter names must follow the same conventions as variable names; see [U] 11.3 Naming conventions.

2. Initial values for parameters are given by including an equal sign and the initial value inside the curly braces: \{b0=1\}, \{param=3.571\}, etc.

3. Linear combinations of variables can be included using the notation \{lc:varlist\}: \{xb: mpg price weight _cons\}, \{score: w x z\}, etc. Parameters of linear combinations are initialized to zero.
Substitutable expressions can include any mathematical expression involving scalars and variables. See [U] 13.2 Operators and [U] 13.3 Functions for more information on expressions.

Example 1: The gamma density function

In an extract of the March 2014 Current Population Survey downloaded from Integrated Public Use Microdata Series (IPUMS), wage contains the wage and salary income earned in tens of thousands of dollars per year for working individuals; see King et al. (2010). We want to model wage using the two-parameter gamma distribution with shape parameter \( \alpha \) and rate parameter \( \beta \). The density function for \( y > 0 \) is

\[
f(y) = \frac{\beta^\alpha}{\Gamma(\alpha)} y^{\alpha-1} \exp(-\beta y) \quad \beta > 0, \alpha > 0
\]

so that the log likelihood for the \( i \)th observation is

\[
\ln(\ell_i) = \alpha \ln(\beta) - \ln\{\Gamma(\alpha)\} + (\alpha - 1) \ln(y_i) - \beta y_i
\]

To fit wage to the two-parameter gamma distribution, we let \( a \) be the parameter name that conforms to Stata naming conventions for \( \alpha \) and \( b \) be the parameter name for \( \beta \). We enclose both in {} in our substitutable expression for the log-likelihood function:

```
. use http://www.stata-press.com/data/r14/cpswage
. mlexp (a)*ln(b) - lngamma(a) + (a)-1*ln(wage) - {b}*wage)
```

```
initial: log likelihood = -<inf> (could not be evaluated)
feasible: log likelihood = -239367.36
rescale: log likelihood = -228037.02
rescale eq: log likelihood = -163560.64
Iteration 0: log likelihood = -163560.64
Iteration 1: log likelihood = -162820.41
Iteration 2: log likelihood = -162808.55
Iteration 3: log likelihood = -162808.55
```

```
Maximum likelihood estimation
Log likelihood = -162808.55 Number of obs = 64,748
```

|          | Coef. | Std. Err. | z     | P>|z|  | [95% Conf. Interval] |
|----------|-------|-----------|-------|------|---------------------|
| a        | 1.097287 | 0.0054134 | 202.70 | 0.000 | 1.086677 - 1.107897 |
| b        | 0.2406718 | 0.0014917 | 161.34 | 0.000 | 0.2377482 - 0.2435954 |

Because we did not specify initial values, mlexp initialized \( \alpha \) and \( \beta \) to be 0. When both parameters are 0, the log-likelihood function cannot be evaluated, because \( \ln(0) \) is undefined. Therefore, in the iteration log above the coefficient table, we see that mlexp reported the initial log likelihood to be \(-<inf>\) (could not be evaluated). When this occurs, mlexp uses a search routine to find alternative initial values that do allow the log-likelihood function to be calculated.
We now initialize \( a \) to 1 and \( b \) to 0.1 the first time that we type them within the substitutable expression:

\[
. \text{mlexp} \ (\{a=1\} * \ln(\{b=.1\}) - \ln\text{gamma}(\{a\}) + (\{a\}-1) * \ln(\text{wage}) - \{b\} * \text{wage})
\]

Maximum likelihood estimation

Log likelihood = -162808.55

|              | Coef.  | Std. Err. | z     | P>|z| | [95% Conf. Interval] |
|--------------|--------|-----------|-------|-----|----------------------|
| /a           | 1.097287 | .0054134 | 202.70 | 0.000 | 1.086677 - 1.107897  |
| /b           | .2406719  | .0014917 | 161.34 | 0.000 | .2377483 - .2435955  |

Even when \text{mlexp} \ can find alternative initial values, specifying your own values facilitates optimization.

By default, initial values of parameters are set to zero, and \text{mlexp} \ performs an iterative search for optimum starting values before beginning maximization. If \text{mlexp} \ cannot find initial parameter values for which it can calculate the log-likelihood function, it will exit with an error message. Restricting the sample or specifying starting values solves this problem.

Use the \text{variables()} \ option, an \text{if} \ qualifier, or an \text{in} \ qualifier to restrict the sample. You can also specify initial values by using the \text{from()} \ option or within the substitutable expression by including an equal sign and the initial value after the parameter. If you specify initial values by using \text{from()} \, they override whatever initial values are given within the substitutable expression. Regardless of whether you specify initial values, \text{mlexp} \ performs a search procedure for better starting values before commencing the first iteration of the maximization routine.

\textbf{Example 2: Linear combinations of covariates}

We frequently want to model the parameters as linear combinations of variables. Continuing \text{example 1}, we see that the mean of the two-parameter gamma distribution is \( E(y) = \alpha/\beta \). By letting \( \alpha = a_1 \text{age} + a_0 \), we model the mean of \text{wage} \ conditional on \text{age} \ as \( E(\text{wage}|\text{age}) = (a_1 \text{age} + a_0)/\beta \). Below we specify \{a: age _cons\} \ to model \( a \) as a linear combination of \text{age} \ and a constant term.
. mlexp ({a:age _cons}*ln({b=.1})-lngamma({a:})+({a:-1})*ln(wage)-{b}*wage)

initial:  log likelihood = -<inf>  (could not be evaluated)
feasible:  log likelihood = -239367.36
rescale:  log likelihood = -228037.02
rescale eq:  log likelihood = -163560.64
Iteration 0:  log likelihood = -163560.64
Iteration 1:  log likelihood = -160123.65
Iteration 2:  log likelihood = -159838.42
Iteration 3:  log likelihood = -159838.38
Iteration 4:  log likelihood = -159838.38

Maximum likelihood estimation

Log likelihood = -159838.38  Number of obs  = 64,748

| Coef.  | Std. Err. | z   | P>|z|  | [95% Conf. Interval] |
|--------|-----------|-----|------|---------------------|
| a      | _cons     |     |      |                     |
| age    | .0194396  | .0002689 | 72.31 | 0.000  | .0189126 .0199665 |
| _cons  | .4108355  | .0096791 | 42.45 | 0.000  | .3918647 .4298062 |
| /b     | .2667954  | .0016423 | 162.45 | 0.000  | .2635765 .2700142 |

The notation \{a: age _cons\} indicates to \texttt{mlexp} that you want a linear combination of the variable age and a constant term. We named the linear combination \texttt{a}, so \texttt{mlexp} names the parameters \texttt{a:age} and \texttt{a:_cons}, respectively.

Once you have declared a linear combination, you can subsequently refer to the linear combination by specifying its name and a colon inside curly braces, as we did in this example. You cannot use the same name for both an individual parameter and a linear combination. However, after a linear combination has been declared, you can refer to the parameter of an individual variable within that linear combination by using the notation \{lc:z\}, where \texttt{lc} is the name of the linear combination, and \texttt{z} is the variable whose parameter you want to reference.

Example 3: Linear combinations of factor variables

Factor variables and time-series operated variables can be included in a \texttt{varlist} defining a linear combination. Continuing example 2, we want to allow different intercepts for males and females in \(\alpha\), and we want different \(\beta\) parameters for males and females. We implement this model below by including \texttt{ibn.female} in each linear combination using \texttt{factor-variable} notation.
Maximum likelihood estimation

Log likelihood = -158130.93 Number of obs = 64,748

|    | Coef.       | Std. Err. | z    | P>|z|    | [95% Conf. Interval] |
|----|-------------|-----------|------|--------|----------------------|
| a  | age         | .020543   | .0002781 | 73.88 | 0.000 | .019998 - .0210881  |
|    | female      |           |       |       |                      |
|    | Male        | .3917619  | .0111697 | 35.07 | 0.000 | .3698696 - .4136542 |
|    | Female      | .4475977  | .0116285 | 38.49 | 0.000 | .4248063 - .4703892 |
| b  | female      |           |       |       |                      |
|    | Male        | .2279862  | .0018677 | 122.07 | 0.000 | .2243256 - .2316468 |
|    | Female      | .3600628  | .0030156 | 119.40 | 0.000 | .3541523 - .3659733 |

Parameter interpretation using margins

The `margins` command can be used after `mlexp` to estimate the effect of a covariate from a set of parameter estimates. The estimated covariate effects can be conditional on the other covariates or population-averaged effects that average out the other covariates.

Example 4

Continuing example 3, we use `margins` to estimate the average wage if everyone in the sample were male and if everyone in the sample were female. The `expression()` option is used to specify the formula for the mean. Wages, measured in tens of thousands of dollars, have a gamma distribution, so the mean is a ratio of the $\alpha$ and $\beta$ parameters. The linear prediction is specified in the expression with `xb()`.

```
. margins i.female, expression(xb(a)/xb(b))
```
When everyone is male, the estimated average wage is 5.45; when everyone is female, the estimated average wage is 3.61.

**Parameter constraints**

Example 5

In examples 1, 2, and 3, we were lucky. The two-parameter gamma density function is defined only when both $\alpha$ and $\beta$ are positive. However, mlexp does not know this; when maximizing the log-likelihood function, it will consider all real values for the parameters. Also recall from above, mlexp will exit with an error message if it cannot find parameter values that produce nonmissing values for the likelihood for each sample observation.

We could reparameterize our model so that we avoid having to directly estimate parameters that are restricted. For example, consider the parameter $\alpha > 0$, and suppose we define the new parameter $\theta = \ln(\alpha)$ so that $\alpha = \exp(\theta)$. With this parameterization, for any real value of $\theta$ that mlexp might try to use when evaluating the log-likelihood function, $\alpha$ is guaranteed to be positive. Below we apply this parameterization to the model in example 1.

```
.mlexp (exp({lna})*{lnb} - lngamma(exp({lna})))
> + (exp({lna})-1)*ln(wage) - exp({lnb})*wage)
initial: log likelihood = -295203.41
alternative: log likelihood = -249215.67
rescale: log likelihood = -230376.58
rescale eq: log likelihood = -166588.81
Iteration 0: log likelihood = -166588.81
Iteration 1: log likelihood = -162845.95
Iteration 2: log likelihood = -162808.56
Iteration 3: log likelihood = -162808.55
Iteration 4: log likelihood = -162808.55
Maximum likelihood estimation
Log likelihood = -162808.55 Number of obs = 64,748

Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
--------- ----------- -------- ------- -------- ------------------
/lna    0.0928409    0.0049334    18.82     0.000     0.0831716    0.1025103
/lnb   -1.424321    0.0061979   -229.81     0.000    -1.436469    -1.412173
```

We can use nlcom to obtain the back-transformed parameter estimates, but first we need to know how to refer to the parameters estimated by mlexp. We can replay the results and request the coefficient legend.

```
.mlexp, coeflegend
Maximum likelihood estimation
Log likelihood = -162808.55 Number of obs = 64,748

Coef. Legend
--------- ---------
/lna    0.0928409   _b[lna:_cons]
/lnb   -1.424321   _b[lnb:_cons]
```
Now we see that we can refer to \texttt{_b[lna:_cons]} and \texttt{_b[lnb:_cons]} in \texttt{nlcom}.

\begin{verbatim}
   . nlcom (a: exp(_b[lna:_cons])) (b: exp(_b[lnb:_cons]))
   a: exp(_b[lna:_cons])
   b: exp(_b[lnb:_cons])
\end{verbatim}

\begin{verbatim}

|    | Coef. | Std. Err. | z    | P>|z|  | [95% Conf. Interval] |
|----|-------|-----------|------|-------|---------------------|
| a  | 1.097287 | .0054134  | 202.70 | 0.000  | 1.086677 1.107897   |
| b  | .2406718  | .0014917  | 161.34 | 0.000  | .2377482 .2435954   |
\end{verbatim}

The optimal value of the log-likelihood function and the back-transformed parameter estimates match those reported in example 1.

However, when you impose nonlinear constraints on linear combinations of covariates, you change the model. These nonlinear constraints change the model because they are not invertible functions of the original parameters. For example, we can use the exponential function to ensure \( \alpha > 0 \) and \( \beta > 0 \) in the model from example 3.

\begin{verbatim}
   . mlexp (exp({a:age ibn.female})*{b:ibn.female} - lngamma(exp({a:})) 
>   + (exp({a:})-1)*ln(wage) - exp({b:})*wage)
\end{verbatim}

\begin{verbatim}
initial: log likelihood = -295203.41
alternative: log likelihood = -249215.67
rescale: log likelihood = -230376.58
rescale eq: log likelihood = -166588.81
Iteration 0: log likelihood = -166588.81
Iteration 1: log likelihood = -160273.12
Iteration 2: log likelihood = -158868.39
Iteration 3: log likelihood = -158864.02
Iteration 4: log likelihood = -158864.02
Maximum likelihood estimation
Log likelihood = -158864.02  Number of obs = 64,748

|    | Coef. | Std. Err. | z    | P>|z|  | [95% Conf. Interval] |
|----|-------|-----------|------|-------|---------------------|
| a  | age   | .0126713  | .0001785 | 70.98 | 0.000  | .0123214 .0130212   |
|    | female| -.3470203  | .009978  | -34.78 | 0.000  | -.3665769 -.3274638 |
|    | Male  | -.3177398  | .0103376 | -30.74 | 0.000  | -.338001 -.2974786  |
|    | Female| -.1502222  | .0085431 | -175.84 | 0.000  | -.1518966 -.1485478 |
| b  | female| .1059358  | .0087602 | -120.93 | 0.000  | .1076528 .1042189   |
\end{verbatim}

The value of the log-likelihood function is now \(-158,864.02\), which is less than the value \(-158,130.93\), which was reported in example 3. The constrained parameterization that keeps \( \alpha > 0 \) and \( \beta > 0 \) has changed the model, and the optimal value of the log-likelihood function in the constrained model is less than the optimal value in the unconstrained model.

Because neither the unconstrained nor the constrained parameterization generates missing predicted values for \( \alpha \) or \( \beta \), we can choose between them. However, if any of the predicted values for \( \alpha \) or \( \beta \) produce missing values for the log-likelihood function using the unconstrained parameterization, we could not compute the log-likelihood function for the unconstrained parameterization, and we would have to use a constrained parameterization.
Specifying derivatives

By default, \texttt{mlexp} calculates derivatives of the log-likelihood function numerically using an algorithm that produces accurate results. However, \texttt{mlexp} will fit your model more quickly (and even more accurately) if you specify analytic derivatives.

You specify derivatives by using substitutable expressions in much the same way as you specify the log-likelihood function. If you specify a linear combination in your log-likelihood function, then you supply a derivative with respect to that linear combination; \texttt{mlexp} then uses the chain rule to obtain the derivatives with respect to the individual parameters.

We will illustrate how to specify derivatives using the probit model for dichotomous outcomes. The log-likelihood function for the probit model is often written as

\[
\ln \ell_i = \begin{cases} 
\ln \Phi(x_i' \beta) & y_i = 1 \\
\ln \Phi(-x_i' \beta) & y_i = 0 
\end{cases}
\]

using the fact that \(1 - \Phi(x_i' \beta) = \Phi(-x_i' \beta)\), where \(\Phi(\cdot)\) is the cumulative standard normal distribution function. If we use the trick suggested by Greene (2012, 691, fn. 7), we can simplify the log-likelihood function, making the derivative calculation easier. Let \(q_i = 2y_i - 1\). Then we can write the log-likelihood function as

\[
\ln \ell_i = \ln \Phi(q_i x_i' \beta)
\]

and the first derivative as

\[
\frac{\partial \ln \ell_i}{\partial \beta} = \frac{q_i \phi(q_i x_i' \beta)}{\Phi(q_i x_i' \beta)} x_i
\]

Example 6: Probit with a linear combination

Now let’s fit a probit model of the indicator for whether an individual is below the official poverty level \(\text{offpov}\) on \(\text{age}\), \(\text{female}\), and a constant. We could specify the parameters and independent variables individually, but we will use a linear combination instead. First, note that

\[
\frac{\partial \ln \ell_i}{\partial x_i' \beta} = \frac{q_i \phi(q_i x_i' \beta)}{\Phi(q_i x_i' \beta)} x_i
\]

When you specify a linear combination of variables, you specify the derivative with respect to the linear combination. That way, if you change the variables in the linear combination, you do not need to change the derivative. To see why this is the case, consider the function \(f(x_i' \beta)\), where \(x_i' \beta\) is a linear combination. Then, using the chain rule, we see that

\[
\frac{\partial f(x_i' \beta)}{\partial \beta_j} = \frac{\partial f(x_i' \beta)}{\partial x_i' \beta} \times \frac{\partial x_i' \beta}{\partial \beta_j} = \frac{\partial f(x_i' \beta)}{\partial x_i' \beta} \times x_{ij}
\]

Once the derivative with respect to the linear combination is known, \texttt{mlexp} can then multiply it by each of the variables in the linear combination to get the full set of derivatives with respect to the parameters needed to maximize the likelihood function. Moreover, the derivative with respect to the linear combination does not depend on the variables within the linear combination, so even if you change the variables in it, you will not need to modify the specification of the corresponding \texttt{derivative()} option.
We type

```
. generate int q = 2*offpov - 1
. mlexp (ln(normal(q*({xb:age i.female _cons})))),
    > deriv(/xb = q*normalden(q*{xb:})/normal(q*{xb:}))
initial:  log likelihood =  -44879.894
alternative: log likelihood =  -27407.718
rescale:   log likelihood =  -17888.147
Iteration 0:  log likelihood =  -17888.147
Iteration 1:  log likelihood =  -15805.22
Iteration 2:  log likelihood =  -15427.598
Iteration 3:  log likelihood =  -15427.04
Iteration 4:  log likelihood =  -15427.04

Maximum likelihood estimation
Log likelihood =  -15427.04  Number of obs =  64,748

| Coef.  | Std. Err. | z     | P>|z|     | [95% Conf. Interval] |
|--------|-----------|-------|--------|---------------------|
| xb     |           |       |        |                     |
| age    | -.0179139 | .0005852 | -30.61 | 0.000  | -.0190608, -.016767 |
| female | .1514014  | .0154565  |  9.80  | 0.000  | .1211072, .1816955 |
| Female |           |         |        |         |                     |
| _cons  | -.8773462 | .0244956 | -35.82 | 0.000  | -.9253567, -.8293357 |
```

After defining q, we specified the log-likelihood function using q and the linear combination xb. We also use xb in specifying the derivative.
 Stored results

mlexp stores the following in e():

Scalars

- \( e(N) \): number of observations
- \( e(k) \): number of parameters
- \( e(k_{aux}) \): number of ancillary parameters
- \( e(k_{eq}) \): number of equations in \( e(b) \)
- \( e(k_{eq\_model}) \): number of equations in overall model test
- \( e(df_m) \): model degrees of freedom
- \( e(ll) \): log likelihood
- \( e(N\_clust) \): number of clusters
- \( e(rank) \): rank of \( e(V) \)
- \( e(ic) \): number of iterations
- \( e(rc) \): return code
- \( e(converged) \): 1 if converged, 0 otherwise

Macros

- \( e(cmd) \): mlexp
- \( e(cmdline) \): command as typed
- \( e(lexp) \): likelihood expression
- \( e(wtype) \): weight type
- \( e(wexp) \): weight expression
- \( e(usrtitle) \): user-specified title
- \( e(usrtitle2) \): user-specified secondary title
- \( e(vcetype) \): title used to label Std. Err.
- \( e(params) \): names of parameters
- \( e(hasderiv) \): yes, if derivative() is specified
- \( e(d_{-j}) \): derivative expression for parameter \( j \)
- \( e(rhs) \): contents of variables()
- \( e(opt) \): type of optimization
- \( e(ml\_method) \): type of ml method
- \( e(technique) \): maximization technique
- \( e(singularHmethod) \): m-marquardt or hybrid; method used when Hessian is singular
- \( e(crittype) \): optimization criterion
- \( e(properties) \): b V
- \( e(estat\_cmd) \): program used to implement estat
- \( e(predict) \): program used to implement predict
- \( e(marginsok) \): predictions allowed by margins
- \( e(marginsnotok) \): predictions disallowed by margins
- \( e(marginsprop) \): signals to the margins command
- \( e(asbalanced) \): factor variables fvset as asbalanced
- \( e(asobserved) \): factor variables fvset as asobserved

Matrices

- \( e(b) \): coefficient vector
- \( e(Cns) \): constraints matrix
- \( e(ilog) \): iteration log (up to 20 iterations)
- \( e(init) \): initial values
- \( e(gradient) \): gradient vector
- \( e(V) \): variance–covariance matrix of the estimators
- \( e(V\_modelbased) \): model-based variance

Functions

- \( e(sample) \): marks estimation sample

</table>

* `lrtest` is not appropriate with `svy` estimation results.
predict

Description for predict

`predict` creates a new variable containing predictions such as linear predictions and equation-level scores.

Menu for predict

Statistics > Postestimation

Syntax for predict

```plaintext
predict [type] newvar [if] [in] [, xb equation(#eqno | eqname)]
predict [type] {stub*|newvar1 ... newvar_q} [if] [in] [, scores]
```
 Scores are only available for observations within the estimation sample. q represents the number of equations in the model.

Options for predict

- `xb` calculates the linear prediction.
- `equation(#eqno | eqname)` specifies the equation for which the linear prediction is desired. Specifying `equation(#1)` indicates that the calculation be made for the first equation. Specifying `equation(demand)` indicates that the calculation be made for the equation named `demand`, assuming there is an equation named `demand` in the model.

  If you specify one new variable name and omit `equation()`, results are the same as if you had specified `equation(#1)`.

  For more information on using `predict` after multiple-equation estimation commands, see [R] predict.

- `scores` calculates the equation-level score variables. The jth new variable will contain the scores for the jth equation of the model.
margins

Description for margins

margins estimates margins of response for linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [, options ]

margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options ]

<table>
<thead>
<tr>

[U] 20 Estimation and postestimation commands
**mlogit — Multinomial (polytomous) logistic regression**

### Description

*mlogit* fits a multinomial logit (MNL) model for a categorical dependent variable with outcomes that have no natural ordering. The actual values taken by the dependent variable are irrelevant. The MNL model is also known as the polytomous logistic regression model. Some people refer to conditional logistic regression as multinomial logistic regression. If you are one of them, see [R] *clogit*.

### Quick start

Multinomial logit model of $y$ on $x_1$, $x_2$, and categorical variable $a$

```
mlogit y x1 x2 i.a
```

As above, but use $y = 1$ as the base outcome even if 1 is not the most frequent

```
mlogit y x1 x2 i.a, baseoutcome(1)
```

Report results as relative-risk ratios

```
mlogit y x1 x2 i.a, rrr
```

Constrain coefficient of $x_1$ to be equal for second and third outcomes

```
constraint 1 [#2=#3]:x1
mlogit y x1 x2 i.a, constraints(1)
```

### Menu

Statistics > Categorical outcomes > Multinomial logistic regression
### Syntax

```
  mlogit depvar [ indepvars ] [ if ] [ in ] [ weight ] [ , options ]
```

`indepvars` may contain factor variables; see [U] 11.4.3 Factor variables.
`indepvars` may contain time-series operators; see [U] 11.4.4 Time-series varlists.
`bootstrap`, `by`, `fp`, `jackknife`, `mfp`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands.
`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] mi estimate.
Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.
`vce()` and weights are not allowed with the `svy` prefix; see [SVY] svy.
`fweight`, `iweight`, and `pweight` are allowed; see [U] 11.1.6 weight.
`coeflegend` does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

### Options

- **Model**
  - `noconstant`; see [R] estimation options.
  - `baseoutcome(#)` specifies the value of `depvar` to be treated as the base outcome. The default is to choose the most frequent outcome.
  - `constraints(clist), collinear`; see [R] estimation options.
vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

If specifying vce(bootstrap) or vce(jackknife), you must also specify baseoutcome().

Reporting level(#); see [R] estimation options.

rrr reports the estimated coefficients transformed to relative-risk ratios, that is, \(e^b\) rather than \(b\); see Description of the model below for an explanation of this concept. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. rrr may be specified at estimation or when replaying previously estimated results.

nocnsreport; see [R] estimation options.

display_options: noci, nopvalues, nomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch; see [R] estimation options.

Maximization maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] maximize. These options are seldom used.

The following option is available with mlogit but is not shown in the dialog box:

coeflegend; see [R] estimation options.

Remarks and examples

Remarks are presented under the following headings:

Description of the model
Fitting unconstrained models
Fitting constrained models

mlogit fits maximum likelihood models with discrete dependent (left-hand-side) variables when the dependent variable takes on more than two outcomes and the outcomes have no natural ordering. If the dependent variable takes on only two outcomes, estimates are identical to those produced by logistic or logit; see [R] logistic or [R] logit. If the outcomes are ordered, see [R] ologit. See [R] logistic for a list of related estimation commands.

Description of the model

Consider the outcomes 1, 2, 3, ..., \( m \) recorded in \( y \), and the explanatory variables \( X \). Assume that there are \( m = 3 \) outcomes: “buy an American car”, “buy a Japanese car”, and “buy a European car”. The values of \( y \) are then said to be “unordered”. Even though the outcomes are coded 1, 2, and 3, the numerical values are arbitrary because \( 1 < 2 < 3 \) does not imply that outcome 1 (buy American) is less than outcome 2 (buy Japanese) is less than outcome 3 (buy European). This unordered categorical property of \( y \) distinguishes the use of \texttt{mlogit} from \texttt{regress} (which is appropriate for a continuous dependent variable), from \texttt{ologit} (which is appropriate for ordered categorical data), and from \texttt{logit} (which is appropriate for two outcomes, which can be thought of as ordered).

In the multinomial logit model, you estimate a set of coefficients, \( \beta^{(1)} \), \( \beta^{(2)} \), and \( \beta^{(3)} \), corresponding to each outcome:

\[
\begin{align*}
\Pr(y = 1) &= \frac{e^{X\beta^{(1)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}} \\
\Pr(y = 2) &= \frac{e^{X\beta^{(2)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}} \\
\Pr(y = 3) &= \frac{e^{X\beta^{(3)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}
\end{align*}
\]

The model, however, is unidentified in the sense that there is more than one solution to \( \beta^{(1)} \), \( \beta^{(2)} \), and \( \beta^{(3)} \) that leads to the same probabilities for \( y = 1 \), \( y = 2 \), and \( y = 3 \). To identify the model, you arbitrarily set one of \( \beta^{(1)} \), \( \beta^{(2)} \), or \( \beta^{(3)} \) to 0—it does not matter which. That is, if you arbitrarily set \( \beta^{(1)} = 0 \), the remaining coefficients \( \beta^{(2)} \) and \( \beta^{(3)} \) will measure the change relative to the \( y = 1 \) group. If you instead set \( \beta^{(2)} = 0 \), the remaining coefficients \( \beta^{(1)} \) and \( \beta^{(3)} \) will measure the change relative to the \( y = 2 \) group. The coefficients will differ because they have different interpretations, but the predicted probabilities for \( y = 1 \), 2, and 3 will still be the same. Thus either parameterization will be a solution to the same underlying model.

Setting \( \beta^{(1)} = 0 \), the equations become

\[
\begin{align*}
\Pr(y = 1) &= \frac{1}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}} \\
\Pr(y = 2) &= \frac{e^{X\beta^{(2)}}}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}} \\
\Pr(y = 3) &= \frac{e^{X\beta^{(3)}}}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}
\end{align*}
\]

The relative probability of \( y = 2 \) to the base outcome is

\[
\frac{\Pr(y = 2)}{\Pr(y = 1)} = e^{X\beta^{(2)}}
\]

Let’s call this ratio the relative risk, and let’s further assume that \( X \) and \( \beta^{(2)}_{k} \) are vectors equal to \((x_1, x_2, \ldots, x_k)\) and \((\beta^{(2)}_1, \beta^{(2)}_2, \ldots, \beta^{(2)}_k)\)' respectively. The ratio of the relative risk for a one-unit change in \( x_i \) is then

\[
\frac{e^{\beta^{(2)}_1 x_1 + \cdots + \beta^{(2)}_i (x_i + 1) + \cdots + \beta^{(2)}_k x_k}}{e^{\beta^{(2)}_1 x_1 + \cdots + \beta^{(2)}_i x_i + \cdots + \beta^{(2)}_k x_k}} = e^{\beta^{(2)}_i}
\]
Thus the exponentiated value of a coefficient is the relative-risk ratio for a one-unit change in the corresponding variable (risk is measured as the risk of the outcome relative to the base outcome).

### Fitting unconstrained models

#### Example 1: A first example

We have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). The insurance is categorized as either an indemnity plan (that is, regular fee-for-service insurance, which may have a deductible or coinsurance rate) or a prepaid plan (a fixed up-front payment allowing subsequent unlimited use as provided, for instance, by an HMO). The third possibility is that the subject has no insurance whatsoever. We wish to explore the demographic factors associated with each subject’s insurance choice. One of the demographic factors in our data is the race of the participant, coded as white or nonwhite:

```
use http://www.stata-press.com/data/r14/sysdsn1
(Health insurance data)
tabulate insure nonwhite, chi2 col
```

</table>

| Pearson chi2(2) | 9.5599     |
| Pr              | 0.008      |

Although `insure` appears to take on the values `Indemnity`, `Prepaid`, and `Uninsure`, it actually takes on the values 1, 2, and 3. The words appear because we have associated a value label with the numeric variable `insure`; see [U] 12.6.3 Value labels.
When we fit a multinomial logit model, we can tell \texttt{mlogit} which outcome to use as the base outcome, or we can let \texttt{mlogit} choose. To fit a model of \texttt{insure} on \texttt{nonwhite}, letting \texttt{mlogit} choose the base outcome, we type

\begin{verbatim}
. mlogit insure nonwhite

Iteration 0:  log likelihood =  -556.59502
Iteration 1:  log likelihood =  -551.78935
Iteration 2:  log likelihood =  -551.78348
Iteration 3:  log likelihood =  -551.78348

Multinomial logistic regression
Number of obs      =       616
LR chi2(2)        =      9.62
Prob > chi2       =     0.0081
Log likelihood    =  -551.78348  Pseudo R2 =     0.0086

insure |      Coef.     Std. Err.      z    P>|z|     [95% Conf. Interval]
--------+-------------------------------------------------------------
      Indemnity  | (base outcome)                        
  Prepaid  |   
    nonwhite  |       .6608212   .2157321     3.06   0.002      .2379942    1.083648
      _cons    |     -.1879149   .0937644    -2.00   0.045    -.3716896   -.0041401
  Uninsure  |   
    nonwhite  |       .3779586   .4075890     0.93   0.354    -.4209011    1.176818
      _cons    |    -1.941934   .1782185   -10.90   0.000   -2.291236   -1.592632
--------+-------------------------------------------------------------

\end{verbatim}

\texttt{mlogit} chose the indemnity outcome as the base outcome and presented coefficients for the outcomes prepaid and uninsured. According to the model, the probability of prepaid for whites (\texttt{nonwhite} = 0) is

\[
\Pr(\text{insure} = \text{Prepaid}) = \frac{e^{-0.188}}{1 + e^{-0.188} + e^{-1.942}} = 0.420
\]

Similarly, for nonwhites, the probability of prepaid is

\[
\Pr(\text{insure} = \text{Prepaid}) = \frac{e^{-0.188+0.661}}{1 + e^{-0.188+0.661} + e^{-1.942+0.378}} = 0.570
\]

These results agree with the column percentages presented by \texttt{tabulate} because the \texttt{mlogit} model is fully saturated. That is, there are enough terms in the model to fully explain the column percentage in each cell. The model chi-squared and the \texttt{tabulate} chi-squared are in almost perfect agreement; both test that the column percentages of \texttt{insure} are the same for both values of \texttt{nonwhite}.

\section*{Example 2: Specifying the base outcome}

By specifying the \texttt{baseoutcome()} option, we can control which outcome of the dependent variable is treated as the base. Left to its own, \texttt{mlogit} chose to make outcome 1, indemnity, the base outcome. To make outcome 2, prepaid, the base, we would type
. mlogit insure nonwhite, base(2)

Iteration 0:  log likelihood = -556.59502
Iteration 1:  log likelihood = -551.78935
Iteration 2:  log likelihood = -551.78348
Iteration 3:  log likelihood = -551.78348

Multinomial logistic regression

Number of obs = 616
LR chi2(2) = 9.62
Prob > chi2 = 0.0081
Log likelihood = -551.78348
Pseudo R2 = 0.0086

insure Coef. Std. Err. z P>|z| [95% Conf. Interval]
Indemnity
nonwhite -.6608212 .2157321 -3.06 0.002 -1.083648 -.2379942
_cons .1879149 .0937644 2.00 0.045 .0041401 .3716896
Prepaid (base outcome)
Uninsure
nonwhite -.2828627 .3977302 -0.71 0.477 -.1.0624 .4966742
_cons -1.754019 .1805145 -9.72 0.000 -2.107821 -1.400217

The baseoutcome() option requires that we specify the numeric value of the outcome, so we could not type base(Prepaid).

Although the coefficients now appear to be different, the summary statistics reported at the top are identical. With this parameterization, the probability of prepaid insurance for whites is

\[
Pr(\text{insure} = \text{Prepaid}) = \frac{1}{1 + e^{.188} + e^{-1.754}} = 0.420
\]

This is the same answer we obtained previously.

\* Example 3: Displaying relative-risk ratios

By specifying rrr, which we can do at estimation time or when we redisplay results, we see the model in terms of relative-risk ratios:

. mlogit, rrr

Multinomial logistic regression

Number of obs = 616
LR chi2(2) = 9.62
Prob > chi2 = 0.0081
Log likelihood = -551.78348
Pseudo R2 = 0.0086

insure RRR Std. Err. z P>|z| [95% Conf. Interval]
Indemnity
nonwhite .516427 .1114099 -3.06 0.002 .3383588 .7882073
_cons 1.206731 .1131483 2.00 0.045 1.004149 1.450183
Prepaid (base outcome)
Uninsure
nonwhite .7536233 .2997387 -0.71 0.477 .3456255 1.643247
_cons .1730769 .0312429 -9.72 0.000 .1215024 .2465434
Looked at this way, the relative risk of choosing an indemnity over a prepaid plan is 0.516 for nonwhites relative to whites.

To illustrate, from the output and discussions of examples 1 and 2 we find that

\[
\Pr(\text{insure} = \text{Indemnity} | \text{white}) = \frac{1}{1 + e^{-1.188} + e^{-1.942}} = 0.507
\]

and thus the relative risk of choosing indemnity over prepaid (for whites) is

\[
\frac{\Pr(\text{insure} = \text{Indemnity} | \text{white})}{\Pr(\text{insure} = \text{Prepaid} | \text{white})} = \frac{0.507}{0.420} = 1.207
\]

For nonwhites,

\[
\Pr(\text{insure} = \text{Indemnity} | \text{not white}) = \frac{1}{1 + e^{-1.188}+0.661 + e^{-1.942}+0.378} = 0.355
\]

and thus the relative risk of choosing indemnity over prepaid (for nonwhites) is

\[
\frac{\Pr(\text{insure} = \text{Indemnity} | \text{not white})}{\Pr(\text{insure} = \text{Prepaid} | \text{not white})} = \frac{0.355}{0.570} = 0.623
\]

The ratio of these two relative risks, hence the name “relative-risk ratio”, is 0.623/1.207 = 0.516, as given in the output under the heading “RRR”.

Technical note

In models where only two categories are considered, the \texttt{mlogit} model reduces to standard \texttt{logit}. Consequently the exponentiated regression coefficients, labeled as RRR within \texttt{mlogit}, are equal to the odds ratios as given when the \texttt{or} option is specified under \texttt{logit}; see \cite{Rlogit}.

As such, always referring to \texttt{mlogit}’s exponentiated coefficients as odds ratios may be tempting. However, the discussion in example 3 demonstrates that doing so would be incorrect. In general \texttt{mlogit} models, the exponentiated coefficients are ratios of relative risks, not ratios of odds.

Example 4: Model with continuous and multiple categorical variables

One of the advantages of \texttt{mlogit} over \texttt{tabulate} is that we can include continuous variables and multiple categorical variables in the model. In examining the data on insurance choice, we decide that we want to control for age, gender, and site of study (the study was conducted in three sites):

\[

   nonwhite    .2170589   .4256361     0.51   0.610    -.6171725    1.05129
   site
      2   -1.211563   .4705127    -2.57   0.010    -2.133751   -.2893747
      3   -.2078123   .3662926    -0.57   0.570    -.9257327    .510108
   _cons   -1.286943   .5923219    -2.17   0.030    -2.447872   -.1260134

These results suggest that the inclination of nonwhites to choose prepaid care is even stronger than it was without controlling. We also see that subjects in site 2 are less likely to be uninsured.

Fitting constrained models

`mlogit` can fit models with subsets of coefficients constrained to be zero, with subsets of coefficients constrained to be equal both within and across equations, and with subsets of coefficients arbitrarily constrained to equal linear combinations of other estimated coefficients.

Before fitting a constrained model, you define the constraints with the `constraint` command; see `[R] constraint`. Once the constraints are defined, you estimate using `mlogit`, specifying the `constraint()` option. Typing `constraint(4)` would use the constraint you previously saved as 4. Typing `constraint(1,4,6)` would use the previously stored constraints 1, 4, and 6. Typing `constraint(1-4,6)` would use the previously stored constraints 1, 2, 3, 4, and 6.

Sometimes you will not be able to specify the constraints without knowing the omitted outcome. In such cases, assume that the omitted outcome is whatever outcome is convenient for you, and include the `baseoutcome()` option when you specify the `mlogit` command.
Example 5: Specifying constraints to test hypotheses

We can use constraints to test hypotheses, among other things. In our insurance-choice model, let’s test the hypothesis that there is no distinction between having indemnity insurance and being uninsured. Indemnity-style insurance was the omitted outcome, so we type

```
  . test [Uninsure]
  ( 1) [Uninsure]age = 0
  ( 2) [Uninsure]male = 0
  ( 3) [Uninsure]nonwhite = 0
  ( 4) [Uninsure]1b.site = 0
  ( 5) [Uninsure]2b.site = 0
  ( 6) [Uninsure]3b.site = 0
  Constraint 4 dropped
  chi2(  5) =  9.31
  Prob > chi2 =  0.0973
```

If indemnity had not been the omitted outcome, we would have typed `test [Uninsure=Indemnity]`.

The results produced by `test` are an approximation based on the estimated covariance matrix of the coefficients. Because the probability of being uninsured is low, the log likelihood may be nonlinear for the uninsured. Conventional statistical wisdom is not to trust the asymptotic answer under these circumstances but to perform a likelihood-ratio test instead.

To use Stata’s `lrtest` (likelihood-ratio test) command, we must fit both the unconstrained and constrained models. The unconstrained model is the one we have previously fit. Following the instruction in [R] `lrtest`, we first store the unconstrained model results:

```
  . estimates store unconstrained
```

To fit the constrained model, we must refit our model with all the coefficients except the constant set to 0 in the `Uninsure` equation. We define the constraint and then refit:

```
  . constr 1 [Uninsure]age = 0
  . constr 2 [Uninsure]male = 0
  . constr 3 [Uninsure]nonwhite = 0
  . constr 4 [Uninsure]1b.site = 0
  . constr 5 [Uninsure]2b.site = 0
  . constr 6 [Uninsure]3b.site = 0
  . constr 4 dropped
  . lrtest
```
. constraint 1 [Uninsure]
. mlogit insure age male nonwhite i.site, constraints(1)
Iteration 0:  log likelihood =  -555.85446
Iteration 1:  log likelihood =  -539.80523
Iteration 2:  log likelihood =  -539.75644
Iteration 3:  log likelihood =  -539.75643

Multinomial logistic regression
Number of obs =  615
 Wald chi2(5)  =   29.70
Log likelihood =  -539.75643  Prob > chi2 =  0.0000

( 1)  [Uninsure]o.age = 0
( 2)  [Uninsure]o.male = 0
( 3)  [Uninsure]o.nonwhite = 0
( 4)  [Uninsure]2o.site = 0
( 5)  [Uninsure]3o.site = 0

insure |  Coef.  Std. Err. z   P>|z|  [95% Conf. Interval]
---------|----------------------|--------|-------------|------------------|

3       | -.5521773  .2187237 -2.52  0.012  -.9808678  -.1234869 |
_cons   |  .1792752  .3171372  0.57  0.572   -.4423023   .8008527 |

Uninsure |                      |        |             |                  |
age     |  0 (omitted)          |        |             |                  |
male    |  0 (omitted)          |        |             |                  |
nonwhite|  0 (omitted)          |        |             |                  |
site    |                      |        |             |                  |
2       |  0 (omitted)          |        |             |                  |
3       |  0 (omitted)          |        |             |                  |
_cons   |-.187351   .1601099 -11.70  0.000  -2.18732  -1.5597  |

We can now perform the likelihood-ratio test:

. lrtest unconstrained

Likelihood-ratio test LR chi2(5)  =   10.79
(Assumption: . nested in unconstrained) Prob > chi2 =  0.0557

The likelihood-ratio chi-squared is 10.79 with 5 degrees of freedom—just slightly greater than the magic \( p = 0.05 \) level—so we should not call this difference significant.

Technical note

In certain circumstances, you should fit a multinomial logit model with conditional logit; see \[R\] clogit. With substantial data manipulation, clogit can handle the same class of models with some interesting additions. For example, if we had available the price and deductible of the most competitive insurance plan of each type, mlogit could not use this information, but clogit could.
mlogit stores the following in e():

Scalars
- `e(N)` number of observations
- `e(N_cd)` number of completely determined observations
- `e(k_out)` number of outcomes
- `e(k)` number of parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(r2_p)` pseudo-$R$-squared
- `e(ll)` log likelihood
- `e(ll_0)` log likelihood, constant-only model
- `e(N_clust)` number of clusters
- `e(chi2)` $\chi^2$
- `e(p)` significance
- `e(k_eq_base)` equation number of the base outcome
- `e(baseout)` the value of `depvar` to be treated as the base outcome
- `e(baseout)` index of the base outcome
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise

Macros
- `e(cmd)` `mlogit`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(chi2type)` Wald or LR; type of model $\chi^2$ test
- `e(vce)` vcetype specified in `vce()`
- `e(vcetype)` title used to label Std. Err.
- `e(eqnames)` names of equations
- `e(baselab)` value label corresponding to base outcome
- `e(opt)` type of optimization
- `e(which)` max or min; whether optimizer is to perform maximization or minimization
- `e(ml_method)` type of ml method
- `e(user)` name of likelihood-evaluator program
- `e(technique)` maximization technique
- `e(properties)` `b V`
- `e(predict)` program used to implement predict
- `e(marginsnotok)` predictions disallowed by margins
- `e(marginsdefault)` default `predict()` specification for margins
- `e(asbalanced)` factor variables `fvset` as `asbalanced`
- `e(asobserved)` factor variables `fvset` as `asobserved`
Methods and formulas

The multinomial logit model is described in Greene (2012, 763–766).

Suppose that there are \( k \) categorical outcomes and—without loss of generality—let the base outcome be 1. The probability that the response for the \( j \)th observation is equal to the \( i \)th outcome is

\[
p_{ij} = \Pr(y_j = i) = \begin{cases} 
1, & \text{if } i = 1 \\
\frac{1}{1 + \sum_{m=2}^{k} \exp(x_j \beta_m)}, & \text{if } i > 1
\end{cases}
\]

where \( x_j \) is the row vector of observed values of the independent variables for the \( j \)th observation and \( \beta_m \) is the coefficient vector for outcome \( m \). The log pseudolikelihood is

\[
\ln L = \sum_j w_j \sum_{i=1}^{k} I_i(y_j) \ln p_{ik}
\]

where \( w_j \) is an optional weight and

\[
I_i(y_j) = \begin{cases} 
1, & \text{if } y_j = i \\
0, & \text{otherwise}
\end{cases}
\]

Newton–Raphson maximum likelihood is used; see [R] maximize.

For constrained equations, the set of constraints is orthogonalized, and a subset of maximizable parameters is selected. For example, a parameter that is constrained to zero is not a maximizable parameter. If two parameters are constrained to be equal to each other, only one is a maximizable parameter.

Let \( r \) be the vector of maximizable parameters. \( r \) is physically a subset of the solution parameters, \( b \). A matrix, \( T \), and a vector, \( m \), are defined as

\[
b = Tr + m
\]
so that

\[
\frac{\partial f}{\partial b} = \frac{\partial f}{\partial r} T'
\]

\[
\frac{\partial^2 f}{\partial b^2} = T \frac{\partial^2 f}{\partial r^2} T'
\]

\(T\) consists of a block form in which one part is a permutation of the identity matrix and the other part describes how to calculate the constrained parameters from the maximizable parameters.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See \texttt{[P] _robust}, particularly \texttt{Maximum likelihood estimators} and \texttt{Methods and formulas}.

\texttt{mlogit} also supports estimation with survey data. For details on VCEs with survey data, see \texttt{[SVY] variance estimation}.

* forecast, hausman, and lrtest are not appropriate with svy estimation results. forecast is also not appropriate with mi estimation results.
predict

**Description for predict**

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

**Menu for predict**

Statistics > Postestimation

**Syntax for predict**

```
predict [type] { stub* | newvar | newvarlist } [ if ] [ in ] [ , statistic outcome(outcome) ]
```

```
predict [type] { stub* | newvarlist } [ if ] [ in ] , scores
```

**statistic** Description

<table>
<thead>
<tr>
<th>Main</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>predicted probabilities; the default</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the linear prediction</td>
</tr>
<tr>
<td>stddp</td>
<td>standard error of the difference in two linear predictions</td>
</tr>
</tbody>
</table>

If you do not specify `outcome()`, `pr` (with one new variable specified), `xb`, and `stdp` assume `outcome(#1)`. You must specify `outcome()` with the `stddp` option.

You specify one or `k` new variables with `pr`, where `k` is the number of outcomes.

You specify one new variable with `xb`, `stdp`, and `stddp`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

**Options for predict**

```
pr, the default, calculates the predicted probabilities. If you do not also specify the `outcome()` option, you specify `k` new variables, where `k` is the number of categories of the dependent variable. Say that you fit a model by typing `mlogit result x1 x2`, and `result` takes on three values. Then you could type `predict p1 p2 p3` to obtain all three predicted probabilities. If you specify the `outcome()` option, you must specify one new variable. Say that `result` takes on the values 1, 2, and 3. Typing `predict p1, outcome(1)` would produce the same `p1`.
```

```
xb calculates the linear prediction. You must also specify the `outcome(outcome)` option.
```

```
stdp calculates the standard error of the linear prediction. You must also specify the `outcome(outcome)` option.
```

```
stddp calculates the standard error of the difference in two linear predictions. You must specify the `outcome(outcome)` option, and here you specify the two particular outcomes of interest inside the parentheses, for example, `predict sed, stddp outcome(1,3)`. 
```
outcome(outcome) specifies the outcome for which the statistic is to be calculated. equation() is a synonym for outcome(): it does not matter which you use. outcome() or equation() can be specified using

#1, #2, ..., where #1 means the first category of the dependent variable, #2 means the second category, etc.;
the values of the dependent variable; or
the value labels of the dependent variable if they exist.

scores calculates equation-level score variables. The number of score variables created will be one less than the number of outcomes in the model. If the number of outcomes in the model were k, then

the first new variable will contain $\frac{\partial \ln L}{\partial (x_j \beta_1)}$;
the second new variable will contain $\frac{\partial \ln L}{\partial (x_j \beta_2)}$;
...
the $(k-1)\text{th}$ new variable will contain $\frac{\partial \ln L}{\partial (x_j \beta_{k-1})}$.

margins

Description for margins

margins estimates margins of response for probabilities and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ... ) [predict(statistic ... ) ... ] [options ]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>probabilities for each outcome</td>
</tr>
<tr>
<td>pr</td>
<td>probability for a specified outcome</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction for a specified outcome</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
<tr>
<td>stddp</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

pr and xb default to the first outcome.

Statistics not allowed with margins are functions of stochastic quantities other than $e(b)$.

For the full syntax, see [R] margins.
Obtaining predicted values

Example 1: Obtaining predicted probabilities

After estimation, we can use \texttt{predict} to obtain predicted probabilities, index values, and standard errors of the index, or differences in the index. For instance, in example 4 of [R] \texttt{mlogit}, we fit a model of insurance choice on various characteristics. We can obtain the predicted probabilities for outcome 1 by typing

\begin{verbatim}
. use http://www.stata-press.com/data/r14/sysdsn1
(Health insurance data)
. mlogit insure age i.male i.nonwhite i.site
(output omitted)
. predict p1 if e(sample), outcome(1)
(option \texttt{pr} assumed; predicted probability)
(29 missing values generated)
. summarize p1
\end{verbatim}

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>p1</td>
<td>615</td>
<td>.476423</td>
<td>.1032279</td>
<td>.169814</td>
<td>.71939</td>
</tr>
</tbody>
</table>

We added the \texttt{i.} prefix to the \texttt{male}, \texttt{nonwhite}, and \texttt{site} variables to explicitly identify them as factor variables. That makes no difference in the estimated results, but we will take advantage of it in later examples. We also included \texttt{if e(sample)} to restrict the calculation to the estimation sample. In example 4 of [R] \texttt{mlogit}, the multinomial logit model was fit on 615 observations, so there must be missing values in our dataset.

Although we typed \texttt{outcome(1)}, specifying 1 for the indemnity outcome, we could have typed \texttt{outcome(Indemnity)}. For instance, to obtain the probabilities for prepaid, we could type

\begin{verbatim}
. predict p2 if e(sample), outcome(Prepaid)
(option \texttt{pr} assumed; predicted probability)
(29 missing values generated)
. summarize p2
\end{verbatim}

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>p2</td>
<td>615</td>
<td>.450407</td>
<td>.1125962</td>
<td>.196410</td>
<td>.788572</td>
</tr>
</tbody>
</table>

We must specify the label exactly as it appears in the underlying value label (or how it appears in the \texttt{mlogit} output), including capitalization.

Here we have used \texttt{predict} to obtain probabilities for the same sample on which we estimated. That is not necessary. We could use another dataset that had the independent variables defined (in our example, \texttt{age}, \texttt{male}, \texttt{nonwhite}, and \texttt{site}) and use \texttt{predict} to obtain predicted probabilities; here, we would not specify \texttt{if e(sample)}. 
Example 2: Obtaining index values

predict can also be used to obtain the index values—the $\sum x_i \hat{\beta}_{i}^{(k)}$—as well as the probabilities:

```
predict idx1, outcome(Indemnity) xb
(1 missing value generated)
.predict idx1, stdp
```

```
summarize idx1

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>idx1</td>
<td>643</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
```

The indemnity outcome was our base outcome—the outcome for which all the coefficients were set to 0—so the index is always 0. For the prepaid and uninsured outcomes, we type

```
predict idx2, outcome(Prepaid) xb
(1 missing value generated)
predict idx3, outcome(Uninsured) xb
(1 missing value generated)
summarize idx2 idx3

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>idx2</td>
<td>643</td>
<td>-.0566113</td>
<td>.4962973</td>
<td>-1.298198</td>
<td>1.700719</td>
</tr>
<tr>
<td>idx3</td>
<td>643</td>
<td>-1.980747</td>
<td>.6018139</td>
<td>-3.112741</td>
<td>-.8258458</td>
</tr>
</tbody>
</table>
```

We can obtain the standard error of the index by specifying the stdp option:

```
predict se2, outcome(Prepaid) stdp
(1 missing value generated)
list p2 idx2 se2 in 1/5

<table>
<thead>
<tr>
<th>p2</th>
<th>idx2</th>
<th>se2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>.3709022</td>
<td>-.4831167</td>
</tr>
<tr>
<td>2.</td>
<td>.4977667</td>
<td>.055111</td>
</tr>
<tr>
<td>3.</td>
<td>.4113073</td>
<td>-.1712106</td>
</tr>
<tr>
<td>4.</td>
<td>.5424927</td>
<td>.3788345</td>
</tr>
<tr>
<td>5.</td>
<td>.-0925817</td>
<td>.1452616</td>
</tr>
</tbody>
</table>
```

We obtained the probability, $p_2$, in the previous example.
Finally, `predict` can calculate the standard error of the difference in the index values between two outcomes with the `stddp` option:

```
. predict se_2_3, outcome(Prepaid,Uninsure) stddp
(1 missing value generated)
. list idx2 idx3 se_2_3 in 1/5
```

<table>
<thead>
<tr>
<th>idx2</th>
<th>idx3</th>
<th>se_2_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>-.4831167</td>
<td>-3.073253</td>
</tr>
<tr>
<td>2.</td>
<td>.055111</td>
<td>-2.715986</td>
</tr>
<tr>
<td>3.</td>
<td>-.1712106</td>
<td>-1.579621</td>
</tr>
<tr>
<td>4.</td>
<td>.3788345</td>
<td>-1.462007</td>
</tr>
<tr>
<td>5.</td>
<td>-.0925817</td>
<td>-2.814022</td>
</tr>
</tbody>
</table>

In the first observation, the difference in the indexes is \(-0.483 - (-3.073) = 2.59\). The standard error of that difference is 0.547.

Example 3: Interpreting results using predictive margins

It is more difficult to interpret the results from `mlogit` than those from `clogit` or `logit` because there are multiple equations. For example, suppose that one of the independent variables in our model takes on the values 0 and 1, and we are attempting to understand the effect of this variable. Assume that the coefficient on this variable for the second outcome, \(\beta^{(2)}\), is positive. We might then be tempted to reason that the probability of the second outcome is higher if the variable is 1 rather than 0. Most of the time, that will be true, but occasionally we will be surprised. The probability of some other outcome could increase even more (say, \(\beta^{(3)} > \beta^{(2)}\)), and thus the probability of outcome 2 would actually fall relative to that outcome. We can use `predict` to help interpret such results.

Continuing with our previously fit insurance-choice model, we wish to describe the model's predictions by race. For this purpose, we can use the method of predictive margins (also known as recycled predictions), in which we vary characteristics of interest across the whole dataset and average the predictions. That is, we have data on both whites and nonwhites, and our individuals have other characteristics as well. We will first pretend that all the people in our data are white but hold their other characteristics constant. We then calculate the probabilities of each outcome. Next we will pretend that all the people in our data are nonwhite, still holding their other characteristics constant. Again we calculate the probabilities of each outcome. The difference in those two sets of calculated probabilities, then, is the difference due to race, holding other characteristics constant.

```
. gen byte nonwhold=nonwhite // save real race
. replace nonwhite=0 // make everyone white
(126 real changes made)
. predict wpind, outcome(Indemnity) // predict probabilities
(option pr assumed; predicted probability)
(1 missing value generated)
. predict wpp, outcome(Prepaid)
(option pr assumed; predicted probability)
(1 missing value generated)
. predict wpnoi, outcome(Uninsure)
(option pr assumed; predicted probability)
(1 missing value generated)
. replace nonwhite=1 // make everyone nonwhite
(644 real changes made)
```
. predict nwpind, outcome(Indemnity)
  (option pr assumed; predicted probability)
(1 missing value generated)

. predict nwpp, outcome(Prepaid)
  (option pr assumed; predicted probability)
(1 missing value generated)

. predict nwpnoi, outcome(Uninsure)
  (option pr assumed; predicted probability)
(1 missing value generated)

. replace nonwhite=nonwhold // restore real race
(518 real changes made)

. summarize wp* nwp*, sep(3)

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Obs</td>
<td>Mean</td>
<td>Std. Dev.</td>
<td>Min</td>
</tr>
<tr>
<td>wpind</td>
<td>643</td>
<td>.5141673</td>
<td>.0872679</td>
<td>.3092903</td>
</tr>
<tr>
<td>wpp</td>
<td>643</td>
<td>.4082052</td>
<td>.0993286</td>
<td>.1964103</td>
</tr>
<tr>
<td>wpnoi</td>
<td>643</td>
<td>.0776275</td>
<td>.0360283</td>
<td>.0273596</td>
</tr>
<tr>
<td>nwpind</td>
<td>643</td>
<td>.3112809</td>
<td>.0817693</td>
<td>.1511329</td>
</tr>
<tr>
<td>nwpp</td>
<td>643</td>
<td>.630078</td>
<td>.0979976</td>
<td>.3871782</td>
</tr>
<tr>
<td>nwpnoi</td>
<td>643</td>
<td>.0586411</td>
<td>.0287185</td>
<td>.0209648</td>
</tr>
</tbody>
</table>

In example 1 of [R] mlogit, we presented a cross-tabulation of insurance type and race. Those values were unadjusted. The means reported above are the values adjusted for age, sex, and site. Combining the results gives

<table>
<thead>
<tr>
<th></th>
<th>Unadjusted</th>
<th>Adjusted</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>white</td>
<td>nonwhite</td>
</tr>
<tr>
<td>Indemnity</td>
<td>0.51</td>
<td>0.36</td>
</tr>
<tr>
<td>Prepaid</td>
<td>0.42</td>
<td>0.57</td>
</tr>
<tr>
<td>Uninsured</td>
<td>0.07</td>
<td>0.07</td>
</tr>
</tbody>
</table>

We find, for instance, after adjusting for age, sex, and site, that although 57% of nonwhites in our data had prepaid plans, 63% of nonwhites chose prepaid plans.

Computing predictive margins by hand was instructive, but we can compute these values more easily using the margins command (see [R] margins). The two margins for the indemnity outcome can be estimated by typing

. margins nonwhite, predict(outcome(Indemnity)) noesample

<table>
<thead>
<tr>
<th></th>
<th>Delta-method</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Margin</td>
<td>Std. Err.</td>
<td>z</td>
<td>P&gt;</td>
</tr>
<tr>
<td>nonwhite</td>
<td>0</td>
<td>.5141673</td>
<td>.0223485</td>
<td>23.01</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>.3112809</td>
<td>.0418049</td>
<td>7.45</td>
</tr>
</tbody>
</table>

margins also estimates the standard errors and confidence intervals of the margins. By default, margins uses only the estimation sample. We added the noesample option so that margins would use the entire sample and produce results comparable to our earlier analysis.
We can use marginsplot to graph the results from margins:

```
. marginsplot
Variables that uniquely identify margins: nonwhite
```

![Predictive Margins of nonwhite with 95% CIs](image)

The margins for the other two outcomes can be computed by typing

```
. margins nonwhite, predict(outcome(Prepaid)) noesample
(output omitted)
. margins nonwhite, predict(outcome(Uninsure)) noesample
(output omitted)
```

The margins for each outcome is computed when no outcome is specified. For example

```
. margins nonwhite, noesample
(output omitted)
```

---

**Technical note**

You can use `predict` to classify predicted values and compare them with the observed outcomes to interpret a multinomial logit model. This is a variation on the notions of sensitivity and specificity for logistic regression. Here we will classify indemnity and prepaid as definitely predicting indemnity, definitely predicting prepaid, and ambiguous.

```
. predict indem, outcome(Indemnity) index // obtain indexes
(1 missing value generated)
. predict prepaid, outcome(Prepaid) index // obtain indexes
(1 missing value generated)
. gen diff = prepaid-indem // obtain difference
(1 missing value generated)
. predict sediff, outcome(Indemnity,Prepaid) stddp // & its standard error
(1 missing value generated)
. gen type = 1 if diff/sediff < -1.96 // definitely indemnity
(504 missing values generated)
. replace type = 3 if diff/sediff > 1.96 // definitely prepaid
(100 real changes made)
```
We can see that the predictive power of this model is modest. There are many misclassifications in both directions, though there are more correctly classified observations than misclassified observations.

Also the uninsured look overwhelmingly as though they might have come from the indemnity system rather than from the prepaid system.

Calculating marginal effects

Example 4

We have already noted that the coefficients from multinomial logit can be difficult to interpret because they are relative to the base outcome. Another way to evaluate the effect of covariates is to examine the marginal effect of changing their values on the probability of observing an outcome.

The margins command can be used for this too. We can estimate the marginal effect of each covariate on the probability of observing the first outcome—indemnity insurance—by typing

```
. margins, dydx(*) predict(outcome(Indemnity))
```

```
Average marginal effects
Number of obs = 615
Model VCE : OIM
Expression : Pr(insure==Indemnity), predict(outcome(Indemnity))
dy/dx w.r.t. : age 1.male 1.nonwhite 2.site 3.site
```

|                      | Delta-method | Std. Err. | z    | P>|z|       | [95% Conf. Interval] |
|----------------------|--------------|-----------|------|----------|---------------------|
| age                  | .0026655     | .001399   | 1.91 | 0.057    | -.0000765 .0054074 |
| 1.male               | -.1295734    | .0450945  | -2.87| 0.004    | -.2179571 -.0411898|
| 1.nonwhite           | -.2032404    | .0482554  | -4.21| 0.000    | -.2978192 -.1086616|
| site                 |              |           |      |          |                     |
| 2                    | .0070995     | .0479993  | 0.15 | 0.882    | -.0869775 .1011765 |
| 3                    | .1216165     | .0505833  | 2.40 | 0.016    | .022475 .220758    |

Note: dy/dx for factor levels is the discrete change from the base level.

By default, margins estimates the average marginal effect over the estimation sample, and that is what we see above. Being male decreases the average probability of having indemnity insurance by 0.130. We also see, from the note at the bottom of the table, that the marginal effect was computed as a discrete change in the probability of being male rather than female. That is why we made male a factor variable when fitting the model.
The dydx(*) option requested that margins estimate the marginal effect for each regressor, dydx(age) would have produced estimates only for the effect of age. margins has many options for controlling how the marginal effect is computed, including the ability to average over subgroups or to compute estimates for specified values of the regressors; see [R] margins.

margins will compute the marginal effects on each outcome when no outcome is specified.

```
. margins, dydx(*)
(output omitted)
```

### Testing hypotheses about coefficients

#### Example 5

test tests hypotheses about the coefficients just as after any estimation command; see [R] test. Note, however, test’s syntax for dealing with multiple-equation models. Because test bases its results on the estimated covariance matrix, we might prefer a likelihood-ratio test; see example 5 in [R] mlogit for an example of lrtest.

If we simply list variables after the test command, we are testing that the corresponding coefficients are zero across all equations:

```
. test 2.site 3.site
   (1) [Indemnity]2o.site = 0
   (2) [Prepaid]2.site = 0
   (3) [Uninsure]2.site = 0
   (4) [Indemnity]3o.site = 0
   (5) [Prepaid]3.site = 0
   (6) [Uninsure]3.site = 0
Constraint 1 dropped
Constraint 4 dropped
   chi2( 4) = 19.74
   Prob > chi2 = 0.0006
```

We can test that all the coefficients (except the constant) in an equation are zero by simply typing the outcome in square brackets:

```
. test [Uninsure]
   (1) [Uninsure]age = 0
   (2) [Uninsure]0b.male = 0
   (3) [Uninsure]1.male = 0
   (4) [Uninsure]0b.nonwhite = 0
   (5) [Uninsure]1.nonwhite = 0
   (6) [Uninsure]1b.site = 0
   (7) [Uninsure]2.site = 0
   (8) [Uninsure]3.site = 0
Constraint 2 dropped
Constraint 4 dropped
Constraint 6 dropped
   chi2( 5) = 9.31
   Prob > chi2 = 0.0973
```

We specify the outcome just as we do with predict; we can specify the label if the outcome variable is labeled, or we can specify the numeric value of the outcome. We would have obtained the same test as above if we had typed test [3] because 3 is the value of insure for the outcome uninsured.

We can combine the two syntaxes. To test that the coefficients on the site variables are 0 in the equation corresponding to the outcome prepaid, we can type
We specified the outcome and then followed that with a colon and the variables we wanted to test.

We can also test that coefficients are equal across equations. To test that all coefficients except the constant are equal for the prepaid and uninsured outcomes, we can type

```
. test [Prepaid=Uninsure]
( 1) [Prepaid]age - [Uninsure]age = 0
( 2) [Prepaid]0b.male - [Uninsure]0b.male = 0
( 3) [Prepaid]1.male - [Uninsure]1.male = 0
( 4) [Prepaid]0b.nonwhite - [Uninsure]0b.nonwhite = 0
( 5) [Prepaid]1.nonwhite - [Uninsure]1.nonwhite = 0
( 6) [Prepaid]1b.site - [Uninsure]1b.site = 0
( 7) [Prepaid]2.site - [Uninsure]2.site = 0
( 8) [Prepaid]3.site - [Uninsure]3.site = 0
Constraint 2 dropped
Constraint 4 dropped
Constraint 6 dropped
```

```
chi2( 5) = 13.80
Prob > chi2 = 0.0169
```

To test that only the site variables are equal, we can type

```
. test [Prepaid=Uninsure]: 2.site 3.site
( 1) [Prepaid]2.site - [Uninsure]2.site = 0
( 2) [Prepaid]3.site - [Uninsure]3.site = 0
```

```
chi2( 2) = 12.68
Prob > chi2 = 0.0018
```

Finally, we can test any arbitrary constraint by simply entering the equation and specifying the coefficients as described in [U] 13.5 Accessing coefficients and standard errors. The following hypothesis is senseless but illustrates the point:

```
. test ([Prepaid]age+[Uninsure]2.site)/2 = 2-[Uninsure]1.nonwhite
( 1) .5*[Prepaid]age + [Uninsure]1.nonwhite + .5*[Uninsure]2.site = 2
```

```
chi2( 1) = 22.45
Prob > chi2 = 0.0000
```

See [R] test for more information about test. The information there about combining hypotheses across test commands (the accumulate option) also applies after mlogit.

Title

more — The —more— message

Description

set more on, which is the default, tells Stata to wait until you press a key before continuing when a —more— message is displayed. set more off tells Stata not to pause or display the —more— message.

set pagesize # sets the number of lines between —more— messages.

Syntax

Tell Stata to pause or not pause for —more— messages

set more {on|off} [, permanently ]

Set number of lines between —more— messages

set pagesize #

Option

permanently specifies that, in addition to making the change right now, the more setting be remembered and become the default setting when you invoke Stata.

Remarks and examples

When you see —more— at the bottom of the screen,

Press . . . and Stata . . .
letter l or Enter displays the next line
letter q acts as if you pressed Break
Spacebar or any other key displays the next screen

You can also click on the More button or click on —more— to display the next screen.

—more— is Stata’s way of telling you that it has something more to show you but that showing it to you will cause the information on the screen to scroll off.

If you type set more off, —more— conditions will never arise, and Stata’s output will scroll by at full speed.

If you type set more on, —more— conditions will be restored at the appropriate places.

Programmers should see [P] more for information on the more programming command.

[P] more — Pause until key is pressed
[P] sleep — Pause for a specified time
[U] 7 —more— conditions
**mprobit — Multinomial probit regression**

### Description

mprobit fits a multinomial probit (MNP) model for a categorical dependent variable with outcomes that have no natural ordering. The actual values taken by the dependent variable are irrelevant. The error terms are assumed to be independent, standard normal, random variables. **asmprobit** relaxes the independence of irrelevant alternatives assumption by specifying correlated latent-variable errors. **asmprobit** also allows heteroskedastic latent-variable errors and alternative-specific independent variables.

### Quick start

Multinomial probit model of $y$ on $x_1$, $x_2$, and categorical $a$

```
   mprobit y x1 x2 i.a
```

As above, but use as the base outcome $y = 3$

```
   mprobit y x1 x2 i.a, baseoutcome(3)
```

Probit variance parameterization of differenced latent errors

```
   mprobit y x1 x2 i.a, probitparam
```

Multiple-imputation estimates with Monte Carlo errors from **mi set data**

```
   mi estimate, merror: mprobit y x1 x2 i.a
```

### Menu

Statistics > Categorical outcomes > Multinomial probit regression
mprobit — Multinomial probit regression

Syntax

mprobit depvar [ indepvars ] [ if ] [ in ] [ weight ] [ , options ]

options

Model

noconstant         suppress constant terms
baseoutcome(# | lbl)  outcome used to normalize location
probitparam         use the probit variance parameterization
constraints(constraints)  apply specified linear constraints
collinear           keep collinear variables

SE/Robust

vce(vcetype)       vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife

Reporting

level(#)           set confidence level; default is level(95)
noconsreport       do not display constraints
display_options    control columns and column formats, row spacing, line width,
                   display of omitted variables and base and empty cells, and
                   factor-variable labeling

Integration

intpoints(#)       number of quadrature points

Maximization

maximize_options   control the maximization process; seldom used
coeflegend         display legend instead of statistics

indepvars may contain factor variables; see [U] 11.4.3 Factor variables.

bootstrap, by, fp, jackknife, mi estimate, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands.

vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

vce() and weights are not allowed with the svy prefix; see [SVY] svy.
fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

Model

noconstant suppresses the $J - 1$ constant terms.

baseoutcome(# | lbl) specifies the outcome used to normalize the location of the latent variable. The base outcome may be specified as a number or a label. The default is to use the most frequent outcome. The coefficients associated with the base outcome are zero.

probitparam specifies to use the probit variance parameterization by fixing the variance of the differenced latent errors between the scale and the base alternatives to be one. The default is to
make the variance of the base and scale latent errors one, thereby making the variance of the difference to be two.

constraints(constraints), collinear; see [R] estimation options.

\textit{constraints} specifies constraints.

\textit{SE/Robust}

\textit{vce(vcetype)} specifies the type of standard error reported, which includes types that are derived from asymptotic theory (\texttt{oim}, \texttt{opg}), that are robust to some kinds of misspecification (\texttt{robust}), that allow for intragroup correlation (\texttt{cluster clustvar}), and that use bootstrap or jackknife methods (\texttt{bootstrap}, \texttt{jackknife}); see [R] \textit{vce} option.

If specifying \texttt{vce(bootstrap)} or \texttt{vce(jackknife)}, you must also specify \texttt{baseoutcome(\ldots)}. If specifying \texttt{vce(bootstrap)} or \texttt{vce(jackknife)}, you must also specify \texttt{baseoutcome(\ldots)}. If specifying \texttt{vce(bootstrap)} or \texttt{vce(jackknife)}, you must also specify \texttt{baseoutcome(\ldots)}.

\textit{Reporting}

\textit{level(#)}; see [R] \textit{estimation options}.

\textit{nocnsreport}; see [R] \textit{estimation options}.

\textit{display_options}: \texttt{noic}, \texttt{nopvalues}, \texttt{noomitted}, \texttt{vsquish}, \texttt{noemptycells}, \texttt{baselevels}, \texttt{allbaselevels}, \texttt{nolabel}, \texttt{fwrapp(\ldots)}, \texttt{fwrapp(style)}, \texttt{cformat(\%fmt)}, \texttt{pformat(\%fmt)}, \texttt{sformat(\%fmt)}, and \texttt{nolstretch}; see [R] \textit{estimation options}.

\textit{Integration}

\textit{intpoints(#)} specifies the number of Gaussian quadrature points to use in approximating the likelihood. The default is 15.

\textit{Maximization}

\textit{maximize_options}: \texttt{difficult}, \texttt{technique(algorithm_spec)}, \texttt{iterate(#)}, \texttt{[no]log}, \texttt{trace}, \texttt{gradient}, \texttt{showstep}, \texttt{hessian}, \texttt{showtolerance}, \texttt{tolerance(#)}, \texttt{ltolerance(#)}, \texttt{nrtolerance(#)}, \texttt{nonrtolerance}, and \texttt{from(init_specs)}; see [R] \textit{maximize}. These options are seldom used.

Setting the optimization type to \texttt{technique(bhhh)} resets the default \textit{vcetype} to \texttt{vce(opg)}.

The following option is available with \texttt{mprobit} but is not shown in the dialog box:

\textit{coeflegend}; see [R] \textit{estimation options}.

\section*{Remarks and examples}

The MNP model is used with discrete dependent variables that take on more than two outcomes that do not have a natural ordering. The stochastic error terms for this implementation of the model are assumed to have independent, standard normal distributions. To use \texttt{mprobit}, you must have one observation for each decision maker in the sample. See [R] \texttt{asmprobit} for another implementation of the MNP model that permits correlated and heteroskedastic errors and is suitable when you have data for each alternative that a decision maker faced.

The MNP model is frequently motivated using a latent-variable framework. The latent variable for the $j$th alternative, $j = 1, \ldots, J$, is

$$
\eta_{ij} = z_i \alpha_j + \xi_{ij}
$$
where the $1 \times q$ row vector $z_i$ contains the observed independent variables for the $i$th decision maker. Associated with $z_i$ are the $J$ vectors of regression coefficients $\alpha_j$. The $\xi_{i,1}, \ldots, \xi_{i,J}$ are distributed independently and identically standard normal. The decision maker chooses the alternative $k$ such that $\eta_{ik} \geq \eta_{im}$ for $m \neq k$.

Suppose that case $i$ chooses alternative $k$, and take the difference between latent variable $\eta_{ik}$ and the $J-1$ others:

$$v_{ijk} = \eta_{ij} - \eta_{ik} = z_i (\alpha_j - \alpha_k) + \xi_{ij} - \xi_{ik} = z_i \gamma_{j'} + \epsilon_{ij'} \tag{1}$$

where $j' = j$ if $j < k$ and $j' = j-1$ if $j > k$ so that $j' = 1, \ldots, J-1$. $\text{Var}(\epsilon_{ij'}) = \text{Var}(\xi_{ij} - \xi_{ik}) = 2$ and $\text{Cov}(\epsilon_{ij'}, \epsilon_{il'}) = 1$ for $j' \neq l'$. The probability that alternative $k$ is chosen is

$$\Pr(\text{i chooses } k) = \Pr(v_{i1k} \leq 0, \ldots, v_{iJ-1, k} \leq 0) = \Pr(\epsilon_{i1} \leq -z_i \gamma_1, \ldots, \epsilon_{iJ-1} \leq -z_i \gamma_{J-1})$$

Hence, evaluating the likelihood function involves computing probabilities from the multivariate normal distribution. That all the covariances are equal simplifies the problem somewhat; see Methods and formulas for details.

In (1), not all $J$ of the $\alpha_j$ are identifiable. To remove the indeterminacy, $\alpha_l$ is set to the zero vector, where $l$ is the base outcome as specified in the baseoutcome() option. That fixes the $l$th latent variable to zero so that the remaining variables measure the attractiveness of the other alternatives relative to the base.

**Example 1**

As discussed in example 1 of [R] mlogit, we have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). Patients may have either an indemnity (fee-for-service) plan or a prepaid plan such as an HMO, or the patient may be uninsured. Demographic variables include age, gender, race, and site. Indemnity insurance is the most popular alternative, so mprobit will choose it as the base outcome by default.

The likelihood function for mprobit is derived under the assumption that all decision-making units face the same choice set, which is the union of all outcomes observed in the dataset. If that is not true for your model, then an alternative is to use the asmprobit command, which does not require this assumption. To do that, you will need to expand the dataset so that each decision maker has \( k_i \) observations, where \( k_i \) is the number of alternatives in the choice set faced by decision maker \( i \). You will also need to create a binary variable to indicate the choice made by each decision maker. Moreover, you will need to use the correlation(independent) and stddev(homoskedastic) options with asmprobit unless you have alternative-specific variables.
mprobit stores the following in e():

Scalars
- `e(N)` number of observations
- `e(k_out)` number of outcomes
- `e(k_points)` number of quadrature points
- `e(k)` number of parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_indvars)` number of independent variables
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(ll)` log simulated-likelihood
- `e(N_clust)` number of clusters
- `e(chi2)` \( \chi^2 \)
- `e(i_base)` base outcome index
- `e(const)` 0 if noconstant is specified, 1 otherwise
- `e(probitparam)` 1 if probitparam is specified, 0 otherwise
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise

Macros
- `e(cmd)` mprobit
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(indvars)` independent variables
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(chi2type)` Wald, type of model \( \chi^2 \) test
- `e(vce)` vcetype specified in vce()
- `e(vcetype)` title used to label Std. Err.
- `e(outeqs)` outcome equations
- `e(out#)` outcome labels, \#=1,...,\( e(k_out) \)
- `e(opt)` type of optimization
- `e(which)` max or min: whether optimizer is to perform maximization or minimization
- `e(ml_method)` type of ml method
- `e(user)` name of likelihood-evaluator program
- `e(technique)` maximization technique
- `e(properties)` b V
- `e(predict)` program used to implement predict
- `e(marginsnotok)` predictions disallowed by margins
- `e(marginsdefault)` default predict() specification for margins
- `e(asbalanced)` factor variables fvset as asbalanced
- `e(asobserved)` factor variables fvset as asobserved
Methods and formulas

See Cameron and Trivedi (2005, chap. 15) for a discussion of multinomial models, including multinomial probit. Long and Freese (2014, chap. 8) discuss the multinomial logistic, multinomial probit, and stereotype logistic regression models, with examples using Stata.

As discussed in Remarks and examples, the latent variables for a \( J \)-alternative model are \( \eta_{ij} = z_i \alpha_j + \xi_{ij} \), for \( j = 1, \ldots, J \), \( i = 1, \ldots, n \), and \( \{ \xi_{i,1}, \ldots, \xi_{i,J} \} \sim \text{i.i.d.} \mathcal{N}(0,1) \). The experimenter observes alternative \( k \) for the \( i \)th observation if \( \eta_{ik} > \eta_{il} \) for \( l \neq k \). For \( j \neq k \), let

\[
v_{ij'} = \eta_{ij} - \eta_{ik} = z_i (\alpha_j - \alpha_k) + \xi_{ij} - \xi_{ik} = z_i \gamma_{j'} + \epsilon_{ij'}
\]

where \( j' = j \) if \( j < k \) and \( j' = j - 1 \) if \( j > k \) so that \( j' = 1, \ldots, J - 1 \). \( \epsilon_i = (\epsilon_{i,1}, \ldots, \epsilon_{i,J-1}) \sim \mathcal{MVN}(0, \Sigma) \), where

\[
\Sigma = \begin{pmatrix}
2 & 1 & 1 & \ldots & 1 \\
1 & 2 & 1 & \ldots & 1 \\
1 & 1 & 2 & \ldots & 1 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
1 & 1 & 1 & \ldots & 2
\end{pmatrix}
\]

Denote the deterministic part of the model as \( \lambda_{ij'} = z_i \gamma_{j'} \); the probability that subject \( i \) chooses outcome \( k \) is

\[
\Pr(y_i = k) = \Pr(v_{i1} \leq 0, \ldots, v_{i,J-1} \leq 0) = \Pr(\epsilon_{i,1} \leq -\lambda_{i,1}, \ldots, \epsilon_{i,J-1} \leq -\lambda_{i,J-1}) = \frac{1}{(2\pi)^{(J-1)/2} |\Sigma|^{1/2}} \int_{-\infty}^{-\lambda_{i,1}} \cdots \int_{-\infty}^{-\lambda_{i,J-1}} \exp \left(-\frac{1}{2} z' \Sigma^{-1} z \right) dz
\]

Because of the exchangeable correlation structure of \( \Sigma \) (\( \rho_{ij} = 1/2 \) for all \( i \neq j \)), we can use Dunnett’s (1989) result to reduce the multidimensional integral to one dimension:

\[
\Pr(y_i = k) = \frac{1}{\sqrt{\pi}} \int_{0}^{\infty} \left\{ \prod_{j=1}^{J-1} \Phi \left(-z\sqrt{2} - \lambda_{ij} \right) + \prod_{j=1}^{J-1} \Phi \left(z\sqrt{2} - \lambda_{ij} \right) \right\} e^{-z^2} dz
\]
Gaussian quadrature is used to approximate this integral, resulting in the \( K \)-point quadrature formula

\[
\Pr(y_i = k) \approx \frac{1}{2} \sum_{k=1}^{K} w_k \left\{ \prod_{j=1}^{J-1} \Phi \left( -\sqrt{2}x_k - \lambda_{ij} \right) + \prod_{j=1}^{J-1} \Phi \left( \sqrt{2}x_k - \lambda_{ij} \right) \right\}
\]

where \( w_k \) and \( x_k \) are the weights and roots of the Laguerre polynomial of order \( K \). In \texttt{mprobit}, \( K \) is specified by the \texttt{intpoints()} option.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See \texttt{[P] _robust}, particularly \texttt{Maximum likelihood estimators} and \texttt{Methods and formulas}.

\texttt{mprobit} also supports estimation with survey data. For details on VCEs with survey data, see \texttt{[SVY] variance estimation}.

### Postestimation commands

The following postestimation commands are available after `mprobit`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contrast</td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td>estat ic</td>
<td>Akaike’s and Schwarz’s Bayesian information criteria (AIC and BIC)</td>
</tr>
<tr>
<td>estat summarize</td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td>estat vce</td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td>estat (svy)</td>
<td>postestimation statistics for survey data</td>
</tr>
<tr>
<td>estimates</td>
<td>cataloging estimation results</td>
</tr>
<tr>
<td>*forecast</td>
<td>dynamic forecasts and simulations</td>
</tr>
<tr>
<td>*hausman</td>
<td>Hausman’s specification test</td>
</tr>
<tr>
<td>lincom</td>
<td>point estimates, standard errors, testing, and inference for linear combinations of coefficients</td>
</tr>
<tr>
<td>*lrtest</td>
<td>likelihood-ratio test</td>
</tr>
<tr>
<td>margins</td>
<td>marginal means, predictive margins, marginal effects, and average marginal effects</td>
</tr>
<tr>
<td>marginsplot</td>
<td>graph the results from margins (profile plots, interaction plots, etc.)</td>
</tr>
<tr>
<td>nlcom</td>
<td>point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients</td>
</tr>
<tr>
<td>predict</td>
<td>predicted probabilities, linear predictions, and standard errors</td>
</tr>
<tr>
<td>predictnl</td>
<td>point estimates, standard errors, testing, and inference for generalized predictions</td>
</tr>
<tr>
<td>pwcompare</td>
<td>pairwise comparisons of estimates</td>
</tr>
<tr>
<td>suest</td>
<td>seemingly unrelated estimation</td>
</tr>
<tr>
<td>test</td>
<td>Wald tests of simple and composite linear hypotheses</td>
</tr>
<tr>
<td>testnl</td>
<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.
predict

**Description for predict**

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

**Menu for predict**

Statistics > Postestimation

**Syntax for predict**

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic outcome(outcome)]
predict [type] { stub* | newvarlist } [if] [in], scores
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>predicted probabilities; the default</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the linear prediction</td>
</tr>
</tbody>
</table>

If you do not specify `outcome()`, `pr` (with one new variable specified), `xb`, and `stdp` assume `outcome(#1)`.

You specify one or `k` new variables with `pr`, where `k` is the number of outcomes.

You specify one new variable with `xb` and `stdp`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

**Options for predict**

- `pr`, the default, calculates the predicted probabilities. If you do not also specify the `outcome()` option, you specify `k` new variables, where `k` is the number of categories of the dependent variable. Say that you fit a model by typing `mprobit result x1 x2`, and `result` takes on three values. Then you could type `predict p1 p2 p3` to obtain all three predicted probabilities. If you specify the `outcome()` option, you must specify one new variable. Say that `result` takes on values 1, 2, and 3. Typing `predict p1, outcome(1)` would produce the same `p1`.

- `xb` calculates the linear prediction, \( x_i \alpha_j \), for alternative \( j \) and individual \( i \). The index, \( j \), corresponds to the outcome specified in `outcome()`.

- `stdp` calculates the standard error of the linear prediction.
outcome(*outcome*) specifies the outcome for which the statistic is to be calculated. *equation*() is a synonym for outcome(): it does not matter which you use. outcome() or equation() can be specified using

#1, #2, ..., where #1 means the first category of the dependent variable, #2 means the second category, etc.;
the values of the dependent variable; or
the value labels of the dependent variable if they exist.

scores calculates the equation-level score variables. The jth new variable will contain the scores for the jth fitted equation.

**margins**

**Description for margins**

margins estimates margins of response for probabilities and linear predictions.

**Menu for margins**

Statistics > Postestimation

**Syntax for margins**

margins [ *marginlist* ] [ , options ]
margins [ *marginlist* ] , predict(*statistic* ...) [ predict(*statistic* ...) ... ] [ options ]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>probabilities for each outcome</td>
</tr>
<tr>
<td>pr</td>
<td>probability for a specified outcome</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction for a specified outcome</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

pr and xb default to the first outcome.

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.

**Remarks and examples**

Once you have fit a multinomial probit model, you can use predict to obtain probabilities that an individual will choose each of the alternatives for the estimation sample, as well as other samples; see [U] 20 Estimation and postestimation commands and [R] predict.
Example 1

In example 1 of [R] mprobit, we fit the multinomial probit model to a dataset containing the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). We can obtain the predicted probabilities by typing

```
use http://www.stata-press.com/data/r14/sysdsn1
(Health insurance data)
mprobit insure age male nonwhite i.site
(output omitted)
predict p1-p3
(option pr assumed; predicted probabilities)
list p1-p3 insure in 1/10
```

<table>
<thead>
<tr>
<th></th>
<th>p1</th>
<th>p2</th>
<th>p3</th>
<th>insure</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>.5961306</td>
<td>.3741824</td>
<td>.029687</td>
<td>Indemnity</td>
</tr>
<tr>
<td>2</td>
<td>.4719296</td>
<td>.4972289</td>
<td>.0308415</td>
<td>Prepaid</td>
</tr>
<tr>
<td>3</td>
<td>.4896086</td>
<td>.4121961</td>
<td>.0981953</td>
<td>Indemnity</td>
</tr>
<tr>
<td>4</td>
<td>.3730529</td>
<td>.5416623</td>
<td>.0852848</td>
<td>Prepaid</td>
</tr>
<tr>
<td>5</td>
<td>.5063069</td>
<td>.4629773</td>
<td>.0307158</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>.4768125</td>
<td>.4923548</td>
<td>.0308327</td>
<td>Prepaid</td>
</tr>
<tr>
<td>7</td>
<td>.5035672</td>
<td>.4657016</td>
<td>.0307312</td>
<td>Prepaid</td>
</tr>
<tr>
<td>8</td>
<td>.3326361</td>
<td>.5580404</td>
<td>.1093235</td>
<td></td>
</tr>
<tr>
<td>9</td>
<td>.4758165</td>
<td>.4384811</td>
<td>.0857024</td>
<td>Uninsure</td>
</tr>
<tr>
<td>10</td>
<td>.5734057</td>
<td>.3316601</td>
<td>.0949342</td>
<td>Prepaid</td>
</tr>
</tbody>
</table>

`insure` contains a missing value for observations 5 and 8. Because of that, those two observations were not used in the estimation. However, because none of the independent variables is missing, `predict` can still calculate the probabilities. Had we typed

```
predict p1-p3 if e(sample)
predict would have filled in missing values for p1, p2, and p3 for those observations because they were not used in the estimation.
```

References

Also see

[R] mprobit — Multinomial probit regression

[U] 20 Estimation and postestimation commands
nbreg — Negative binomial regression

Description

nbreg fits a negative binomial regression model for a nonnegative count dependent variable. In this model, the count variable is believed to be generated by a Poisson-like process, except that the variation is allowed to be greater than that of a true Poisson. This extra variation is referred to as overdispersion.

gnbreg fits a generalization of the negative binomial mean-dispersion model; the shape parameter $\alpha$ may also be parameterized.

Quick start

Negative binomial model of $y$ on $x1$ and categorical variable $a$

```
nbreg y x1 i.a
```

As above, but report results as incidence-rate ratios

```
nbreg y x1 i.a, irr
```

As above, and specify exposure variable $evar$

```
nbreg y x1 i.a, irr exposure(evar)
```

Generalized negative binomial model with shape parameter $\alpha$ a function of $x2$ and $x3$

```
gnbreg y x1 i.a, lnalpha(x2 x3)
```

Add log of exposure, $\ln(evar)$, as an offset

```
gnbreg y x1 i.a, lnalpha(x2 x3) offset(ln(evar))
```

Menu

nbreg

Statistics > Count outcomes > Negative binomial regression

gnbreg

Statistics > Count outcomes > Generalized negative binomial regression
### Syntax

**Negative binomial regression model**

```
nbreg depvar [ indepvars ] [ if ] [ in ] [ weight ] [ , nbreg_options ]
```

**Generalized negative binomial model**

```
gnbreg depvar [ indepvars ] [ if ] [ in ] [ weight ] [ , gnbreg_options ]
```

coeflegend                         display legend instead of statistics
```
- **nbreg** — Negative binomial regression

<table>
<thead>
<tr>
<th><strong>gnbreg—options</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
</table>

### Model

- **noconstant** suppress constant term
- **lnalpha(varlist)** dispersion model variables
- **exposure(varname_e)** include ln(varname_e) in model with coefficient constrained to 1
- **offset(varname_o)** include varname_o in model with coefficient constrained to 1
- **constraints(constraints)** apply specified linear constraints
- **collinear** keep collinear variables

### SE/Robust

- **vce(vcetype)** vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife

### Reporting

- **level(#)** set confidence level; default is level(95)
- **irr** report incidence-rate ratios
- **nocnsreport** do not display constraints
- **display_options** control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

### Maximization

- **maximize_options** control the maximization process; seldom used
- **coeflegend** display legend instead of statistics

### Options for nbreg

- **indepvars** and **varlist** may contain factor variables; see [U] 11.4.3 Factor variables.
- **depvar**, **indepvars**, **varname_e**, and **varname_o** may contain time-series operators (nbreg only); see [U] 11.4.4 Time-series varlists.

- **bootstrap**, **by (nbreg only)**, **fp (nbreg only)**, **jackknife**, **mfp (nbreg only)**, **mi estimate**, **nestreg (nbreg only)**, **rolling**, **statsby**, **stepwise**, and **svy** are allowed; see [U] 11.1.10 Prefix commands.

- **vce(bootstrap)** and **vce(jackknife)** are not allowed with the **mi estimate** prefix; see [MI] mi estimate.

- **Weights are not allowed with the bootstrap prefix; see [R] bootstrap.**
- **vce()** and weights are not allowed with the **svy** prefix; see [SVY] svy.
- **fweight**, **iweight**, and **pweight** are allowed; see [U] 11.1.6 weight.
- **coeflegend** does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

---

**Options for nbreg**

- **noconstant** suppress constant term; see [R] estimation options.

- **dispersion(mean | constant)** specifies the parameterization of the model. **dispersion(mean)**, the default, yields a model with dispersion equal to $1 + \alpha \exp(x_j\beta + \text{offset}_j)$; that is, the dispersion is a function of the expected mean: $\exp(x_j\beta + \text{offset}_j)$. **dispersion(constant)** has dispersion equal to $1 + \delta$; that is, it is a constant for all observations.

- **exposure(varname_e)**, **offset(varname_o)**, **constraints(constraints)**, **collinear**; see [R] estimation options.
vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

Reporting

level(#) ; see [R] estimation options.

nolrtest suppresses fitting the Poisson model. Without this option, a comparison Poisson model is fit, and the likelihood is used in a likelihood-ratio test of the null hypothesis that the dispersion parameter is zero.

irr reports estimated coefficients transformed to incidence-rate ratios, that is, \(e^{\beta_i}\) rather than \(\beta_i\). Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. irr may be specified at estimation or when replaying previously estimated results.

nocnsreport; see [R] estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrappon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] estimation options.

Maximization

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no] log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] maximize. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following option is available with nbreg but is not shown in the dialog box:

coeflegend; see [R] estimation options.

Options for gnbreg

Model

noconstant; see [R] estimation options.

lnalpha(varlist) allows you to specify a linear equation for \(\ln \alpha\). Specifying lnalpha(male old) means that \(\ln \alpha = \gamma_0 + \gamma_1 \text{male} + \gamma_2 \text{old}\), where \(\gamma_0\), \(\gamma_1\), and \(\gamma_2\) are parameters to be estimated along with the other model coefficients. If this option is not specified, gnbreg and nbreg will produce the same results because the shape parameter will be parameterized as a constant.

exposure(varname_e), offset(varname_o), constraints(constraints), collinear; see [R] estimation options.
vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

Reporting

level(#) ; see [R] estimation options.

irr reports estimated coefficients transformed to incidence-rate ratios, that is, $e^{\beta_i}$ rather than $\beta_i$. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. irr may be specified at estimation or when replaying previously estimated results.

cnrsreport; see [R] estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabe, fwrap(#), fwraption(style), cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch; see [R] estimation options.

Maximization

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] maximize. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following option is available with gnbreg but is not shown in the dialog box:

cflegendl; see [R] estimation options.

Remarks and examples

Remarks are presented under the following headings:

Introduction to negative binomial regression

nbreg
gnbreg

Introduction to negative binomial regression

Negative binomial regression models the number of occurrences (counts) of an event when the event has extra-Poisson variation, that is, when it has overdispersion. The Poisson regression model is

$$y_j \sim \text{Poisson}(\mu_j)$$

where

$$\mu_j = \exp(x_j \beta + \text{offset}_j)$$
for observed counts $y_j$ with covariates $x_j$ for the $j$th observation. One derivation of the negative binomial mean-dispersion model is that individual units follow a Poisson regression model, but there is an omitted variable $\nu_j$, such that $e^{\nu_j}$ follows a gamma distribution with mean 1 and variance $\alpha$:

$$y_j \sim \text{Poisson}(\mu_j^*)$$

where

$$\mu_j^* = \exp(x_j\beta + \text{offset}_j + \nu_j)$$

and

$$e^{\nu_j} \sim \text{Gamma}(1/\alpha, \alpha)$$

With this parameterization, a Gamma$(a,b)$ distribution will have expectation $ab$ and variance $ab^2$.

We refer to $\alpha$ as the Gamma$(a,b)$ distribution will have expectation $ab$ and variance $ab^2$. The larger $\alpha$ is, the greater the overdispersion. The Poisson model corresponds to $\alpha = 0$. nbreg parameterizes $\alpha$ as $\ln \alpha$. gnbreg allows $\ln \alpha$ to be modeled as $\ln \alpha_j = z_j\gamma$, a linear combination of covariates $z_j$.

nbreg will fit two different parameterizations of the negative binomial model. The default, described above and also given by the dispersion(mean) option, has dispersion for the $j$th observation equal to $1 + \alpha \exp(x_j\beta + \text{offset}_j)$. This is seen by noting that the above implies that

$$\mu_j^* \sim \text{Gamma}(1/\alpha, \alpha \mu_j)$$

and thus

$$\text{Var}(y_j) = E \left\{ \text{Var}(y_j | \mu_j^*) \right\} + \text{Var} \left\{ E(y_j | \mu_j^*) \right\}$$

$$= E(\mu_j^*) + \text{Var}(\mu_j^*)$$

$$= \mu_j(1 + \alpha \mu_j)$$

The alternative parameterization, given by the dispersion(constant) option, has dispersion equal to $1 + \delta$; that is, it is constant for all observations. This is so because the constant-dispersion model assumes instead that

$$\mu_j^* \sim \text{Gamma}(\mu_j/\delta, \delta)$$

and thus $\text{Var}(y_j) = \mu_j(1 + \delta)$. The Poisson model corresponds to $\delta = 0$.

For detailed derivations of both models, see Cameron and Trivedi (2013, 80–89). In particular, note that the mean-dispersion model is known as the NB2 model in their terminology, whereas the constant-dispersion model is referred to as the NB1 model.

See Long and Freese (2014) and Cameron and Trivedi (2010, chap. 17) for a discussion of the negative binomial regression model with Stata examples and for a discussion of other regression models for count data.

Hilbe (2011) provides an extensive review of the negative binomial model and its variations, using Stata examples.
It is not uncommon to posit a Poisson regression model and observe a lack of model fit. The following data appeared in Rodríguez (1993):

```

LR test of alpha=0: chibar2(01) = 4056.27 Prob >= chibar2 = 0.000

Our original Poisson model is a special case of the negative binomial—it corresponds to $\alpha = 0$. `nbreg`, however, estimates $\alpha$ indirectly, estimating instead $\ln \alpha$. In our model, $\ln \alpha = 0.594$, meaning that $\alpha = 1.81$ (`nbreg` undoes the transformation for us at the bottom of the output).

To test $\alpha = 0$ (equivalent to $\ln \alpha = -\infty$), `nbreg` performs a likelihood-ratio test. The staggering $\chi^2$ value of 4,056 asserts that the probability that we would observe these data conditional on $\alpha = 0$ is virtually zero, that is, conditional on the process being Poisson. The data are not Poisson. It is not accidental that this $\chi^2$ value is close to the goodness-of-fit statistic from the Poisson regression itself.

## Technical note

The usual Gaussian test of $\alpha = 0$ is omitted because this test occurs on the boundary, invalidating the usual theory associated with such tests. However, the likelihood-ratio test of $\alpha = 0$ has been modified to be valid on the boundary. In particular, the null distribution of the likelihood-ratio test statistic is not the usual $\chi^2_1$, but rather a 50:50 mixture of a $\chi^2_0$ (point mass at zero) and a $\chi^2_1$, denoted as $\chi^2_{01}$. See Gutierrez, Carter, and Drukker (2001) for more details.

## Technical note

The negative binomial model deals with cases in which there is more variation than would be expected if the process were Poisson. The negative binomial model is not helpful if there is less than Poisson variation—if the variance of the count variable is less than its mean. However, underdispersion is uncommon. Poisson models arise because of independently generated events. Overdispersion comes about if some of the parameters (causes) of the Poisson processes are unknown. To obtain underdispersion, the sequence of events somehow would have to be regulated; that is, events would not be independent but controlled based on past occurrences.
gnbreg

`gnbreg` is a generalization of `nbreg`, dispersion(mean). Whereas in `nbreg`, one \( \ln \alpha \) is estimated, `gnbreg` allows \( \ln \alpha \) to vary, observation by observation, as a linear combination of another set of covariates: \( \ln \alpha_j = z_j \gamma \).

We will assume that the number of deaths is a function of age, whereas the \( \ln \alpha \) parameter is a function of cohort. To fit the model, we type

```
.gnbreg deaths age_mos, lnalpha(i.cohort) offset(logexp)
```

Fitting constant-only model:

```
Iteration 0:  log likelihood = -187.067  (not concave)
Iteration 1:  log likelihood = -138.13047
Iteration 2:  log likelihood = -133.83164
Iteration 3:  log likelihood = -131.59551
Iteration 4:  log likelihood = -131.5795
Iteration 5:  log likelihood = -131.57948
Iteration 6:  log likelihood = -131.57948
```

Fitting full model:

```
Iteration 0:  log likelihood = -124.34327
Iteration 1:  log likelihood = -117.76701
Iteration 2:  log likelihood = -117.56403
Iteration 3:  log likelihood = -117.56164
Iteration 4:  log likelihood = -117.56164
```

Generalized negative binomial regression

```
Number of obs = 21  LR chi2(1) = 28.04
Prob > chi2 = 0.0000  Pseudo R2 = 0.1065
Log likelihood = -117.56164
```

| deaths   | Coef.  | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|----------|--------|-----------|------|-----|----------------------|
| deaths   | 0.0516657 | 0.0051747 | -9.98 | 0.000 | -0.061808 to 0.0415233 |
| age_mos  | -1.867225 | 0.2227944 | -8.38 | 0.000 | -2.303894 to -1.430556 |
| _cons    | -1.867225 | 0.2227944 | -8.38 | 0.000 | -2.303894 to -1.430556 |
| logexp   | 1 (offset) | 0.0516657 | -9.98 | 0.000 | -0.061808 to 0.0415233 |

| lnlalpha | Coef.  | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|----------|--------|-----------|------|-----|----------------------|
| cohort   | 1960-1967 | 0.0939546 | 0.7187747 | 0.13 | 0.896 | -1.314818 to 1.502727 |
|          | 1968-1976 | 0.0815279 | 0.7365476 | 0.11 | 0.912 | -1.362079 to 1.525135 |
| _cons    | -0.4759581 | 0.5156502 | -0.92 | 0.356 | -1.486614 to 0.5346978 |

We find that age is a significant determinant of the number of deaths. The standard errors for the variables in the \( \ln \alpha \) equation suggest that the overdispersion parameter does not vary across cohorts. We can test this assertion by typing

```
.test 2.cohort 3.cohort
```

( 1) [lnalpha]2.cohort = 0
( 2) [lnalpha]3.cohort = 0

```
ch2( 2) = 0.02  Prob > ch2 = 0.9904
```

There is no evidence of variation by cohort in these data.
Technical note

Note the intentional absence of a likelihood-ratio test for $\alpha = 0$ in \texttt{gnbreg}. The test is affected by the same boundary condition that affects the comparison test in \texttt{nbreg}; however, when $\alpha$ is parameterized by more than a constant term, the null distribution becomes intractable. For this reason, we recommend using \texttt{nbreg} to test for overdispersion and, if you have reason to believe that overdispersion exists, only then modeling the overdispersion using \texttt{gnbreg}.

Stored results

\texttt{nbreg} and \texttt{gnbreg} store the following in \texttt{e()}:

Scalars

- \texttt{e(N)}: number of observations
- \texttt{e(k)}: number of parameters
- \texttt{e(k_aux)}: number of auxiliary parameters
- \texttt{e(k_eq)}: number of equations in \texttt{e(b)}
- \texttt{e(k_eq_model)}: number of equations in overall model test
- \texttt{e(k_dv)}: number of dependent variables
- \texttt{e(df_m)}: model degrees of freedom
- \texttt{e(r2_p)}: pseudo-$R^2$-squared
- \texttt{e(ll)}: log likelihood
- \texttt{e(ll0)}: log likelihood, constant-only mode
- \texttt{e(llc)}: log likelihood, comparison model
- \texttt{e(alpha)}: value of alpha
- \texttt{e(delta)}: value of delta
- \texttt{e(N_clust)}: number of clusters
- \texttt{e(chi2)}: $\chi^2$
- \texttt{e(chi2_c)}: $\chi^2$ for comparison test
- \texttt{e(p)}: significance
- \texttt{e(rank)}: rank of \texttt{e(V)}
- \texttt{e(rank0)}: rank of \texttt{e(V)} for constant-only model
- \texttt{e(ic)}: number of iterations
- \texttt{e(rc)}: return code
- \texttt{e(converged)}: 1 if converged, 0 otherwise

Macros

- \texttt{e(cmd)}: \texttt{nbreg} or \texttt{gnbreg}
- \texttt{e(cmdline)}: command as typed
- \texttt{e(depvar)}: name of dependent variable
- \texttt{e(wtype)}: weight type
- \texttt{e(wexp)}: weight expression
- \texttt{e(title)}: title in estimation output
- \texttt{e(clustvar)}: name of cluster variable
- \texttt{e(offset)}: linear offset variable (\texttt{nbreg})
- \texttt{e(offset1)}: linear offset variable (\texttt{gnbreg})
- \texttt{e(chi2type)}: Wald or LR; type of model $\chi^2$ test
- \texttt{e(chi2_ct)}: Wald or LR; type of model $\chi^2$ test corresponding to \texttt{e(chi2_c)}
- \texttt{e(diag)}: mean or constant
- \texttt{e(vcetype)}: \texttt{vcetype} specified in \texttt{vce()}

Methods and formulas

See [R] poisson and Johnson, Kemp, and Kotz (2005, chap. 4) for an introduction to the Poisson distribution.

Methods and formulas are presented under the following headings:

Mean-dispersion model
Constant-dispersion model

Mean-dispersion model

A negative binomial distribution can be regarded as a gamma mixture of Poisson random variables. The number of times something occurs, \( y_j \), is distributed as Poisson\( (\nu_j \mu_j) \). That is, its conditional likelihood is

\[
 f(y_j \mid \nu_j) = \frac{(\nu_j \mu_j)^{y_j} e^{-\nu_j \mu_j}}{\Gamma(y_j + 1)}
\]

where \( \mu_j = \exp(x_j \beta + \text{offset}_j) \) and \( \nu_j \) is an unobserved parameter with a Gamma\( (1/\alpha, \alpha) \) density:

\[
 g(\nu) = \frac{\nu^{(1-\alpha)/\alpha} e^{-\nu/\alpha}}{\alpha^{1/\alpha} \Gamma(1/\alpha)}
\]

This gamma distribution has mean 1 and variance \( \alpha \), where \( \alpha \) is our ancillary parameter.

The unconditional likelihood for the \( j \)th observation \( \alpha \), where \( \alpha \) is our ancillary parameter.

The unconditional likelihood for the \( j \)th observation is therefore

\[
 f(y_j) = \int_0^\infty f(y_j \mid \nu) g(\nu) d\nu = \frac{\Gamma(m + y_j)}{\Gamma(y_j + 1) \Gamma(m)} p_j^m (1 - p_j)^{y_j}
\]

where \( p_j = 1/(1 + \alpha \mu_j) \) and \( m = 1/\alpha \). Solutions for \( \alpha \) are handled by searching for \( \ln(\alpha) \) because \( \alpha \) must be greater than zero.

The log likelihood (with weights \( w_j \) and offsets) is given by

\[
 m = 1/\alpha \quad p_j = 1/(1 + \alpha \mu_j) \quad \mu_j = \exp(x_j \beta + \text{offset}_j)
\]

\[
 \ln L = \sum_{j=1}^n w_j \left[ \ln\{\Gamma(m + y_j)\} - \ln\{\Gamma(y_j + 1)\} 
\right.
\]

\[
 - \ln\{\Gamma(m)\} + m \ln(p_j) + y_j \ln(1 - p_j)
\]

For gnbreg, \( \alpha \) can vary across the observations according to the parameterization \( \ln(\alpha_j) = z_j \gamma \).
Constant-dispersion model

The constant-dispersion model assumes that $y_j$ is conditionally distributed as $\text{Poisson}(\mu_j^*)$, where $\mu_j^* \sim \text{Gamma}(\mu_j/\delta, \delta)$ for some dispersion parameter $\delta$ (by contrast, the mean-dispersion model assumes that $\mu_j^* \sim \text{Gamma}(1/\alpha, \alpha \mu_j)$). The log likelihood is given by

$$m_j = \mu_j/\delta \quad p = 1/(1 + \delta)$$

$$\ln L = \sum_{j=1}^{n} w_j \left[ \ln \left\{ \Gamma(m_j + y_j) \right\} - \ln \left\{ \Gamma(y_j + 1) \right\} - \ln \left\{ \Gamma(m_j) \right\} + m_j \ln(p) + y_j \ln(1 - p) \right]$$

with everything else defined as before in the calculations for the mean-dispersion model.

`nbreg` and `gnbreg` support the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly Maximum likelihood estimators and Methods and formulas.

These commands also support estimation with survey data. For details on VCEs with survey data, see [SVY] variance estimation.

[R] zinb — Zero-inflated negative binomial regression

[ME] membreg — Multilevel mixed-effects negative binomial regression

[M] estimation — Estimation commands for use with mi estimate

[SVY] svy estimation — Estimation commands for survey data

[XT] xtnbreg — Fixed-effects, random-effects, & population-averaged negative binomial models

[U] 20 Estimation and postestimation commands
Postestimation commands

The following postestimation commands are available after `nbreg` and `gnbreg`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>contrast</code></td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td><code>estat ic</code></td>
<td>Akaike’s and Schwarz’s Bayesian information criteria (AIC and BIC)</td>
</tr>
<tr>
<td><code>estat summarize</code></td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td><code>estat vce</code></td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td><code>estat (svy)</code></td>
<td>postestimation statistics for survey data</td>
</tr>
<tr>
<td><code>estimates</code></td>
<td>cataloging estimation results</td>
</tr>
<tr>
<td><code>forecast</code></td>
<td>dynamic forecasts and simulations</td>
</tr>
<tr>
<td><code>hausman</code></td>
<td>Hausman’s specification test</td>
</tr>
<tr>
<td><code>lincom</code></td>
<td>point estimates, standard errors, testing, and inference for linear combinations of coefficients</td>
</tr>
<tr>
<td><code>linktest</code></td>
<td>link test for model specification</td>
</tr>
<tr>
<td><code>lrtest</code></td>
<td>likelihood-ratio test</td>
</tr>
<tr>
<td><code>margins</code></td>
<td>marginal means, predictive margins, marginal effects, and average marginal effects</td>
</tr>
<tr>
<td><code>marginsplot</code></td>
<td>graph the results from margins (profile plots, interaction plots, etc.)</td>
</tr>
<tr>
<td><code>nlcom</code></td>
<td>point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients</td>
</tr>
<tr>
<td><code>predict</code></td>
<td>predictions, residuals, influence statistics, and other diagnostic measures</td>
</tr>
<tr>
<td><code>predictnl</code></td>
<td>point estimates, standard errors, testing, and inference for generalized predictions</td>
</tr>
<tr>
<td><code>pwcompare</code></td>
<td>pairwise comparisons of estimates</td>
</tr>
<tr>
<td><code>suest</code></td>
<td>seemingly unrelated estimation</td>
</tr>
<tr>
<td><code>test</code></td>
<td>Wald tests of simple and composite linear hypotheses</td>
</tr>
<tr>
<td><code>testnl</code></td>
<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.
predict

Description for predict

predict creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, standard errors, and predicted values.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
predict [type] {stub | newvar reg newvar disp} [if] [in], scores
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main</td>
<td></td>
</tr>
<tr>
<td>n</td>
<td>number of events; the default</td>
</tr>
<tr>
<td>ir</td>
<td>incidence rate (equivalent to predict ..., n nooffset)</td>
</tr>
<tr>
<td>pr(n)</td>
<td>probability Pr(y_j = n)</td>
</tr>
<tr>
<td>pr(a,b)</td>
<td>probability Pr(a ≤ y_j ≤ b)</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the linear prediction</td>
</tr>
</tbody>
</table>

In addition, relevant only after gnbreg are the following:

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main</td>
<td></td>
</tr>
<tr>
<td>alpha</td>
<td>predicted values of α_j</td>
</tr>
<tr>
<td>lnalpha</td>
<td>predicted values of lnα_j</td>
</tr>
<tr>
<td>stdplna</td>
<td>standard error of predicted lnα_j</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

n, the default, calculates the predicted number of events, which is \( \exp(x_j\beta) \) if neither offset(varname_o) nor exposure(varname_e) was specified when the model was fit; \( \exp(x_j\beta + \text{offset}_j) \) if offset() was specified; or \( \exp(x_j\beta) \times \text{exposure}_j \) if exposure() was specified.

ir calculates the incidence rate \( \exp(x_j\beta) \), which is the predicted number of events when exposure is 1. This is equivalent to specifying both the n and the nooffset options.
pr(n) calculates the probability Pr(yj = n), where n is a nonnegative integer that may be specified as a number or a variable.

pr(a,b) calculates the probability Pr(a ≤ yj ≤ b), where a and b are nonnegative integers that may be specified as numbers or variables;

  b missing (b ≥ .) means +∞;
  pr(20,) calculates Pr(yj ≥ 20);
  pr(20,b) calculates Pr(yj ≥ 20) in observations for which b ≥ . and calculates Pr(20 ≤ yj ≤ b) elsewhere.
  pr(. ,b) produces a syntax error. A missing value in an observation of the variable a causes a missing value in that observation for pr(a,b).

xb calculates the linear prediction, which is xjβ if neither offset() nor exposure() was specified; xjβ + offsetj if offset() was specified; or xjβ + ln(exposurej) if exposure() was specified; see nooffset below.

stdp calculates the standard error of the linear prediction.

alpha, lnalpha, and stdplna are relevant after gnbreg estimation only; they produce the predicted values of αj, lnαj, and the standard error of the predicted lnαj, respectively.

nooffset is relevant only if you specified offset() or exposure() when you fit the model. It modifies the calculations made by predict so that they ignore the offset or exposure variable; the linear prediction is treated as xjβ rather than as xjβ + offsetj or xjβ + ln(exposurej). Specifying predict ..., nooffset is equivalent to specifying predict ..., ir.

scores calculates equation-level score variables.

  The first new variable will contain ∂ln L/∂(xjβ).
  The second new variable will contain ∂ln L/∂(lnαj) for dispersion(mean) and gnbreg.
  The second new variable will contain ∂ln L/∂(lnδ) for dispersion(constant).
margins

Description for margins

margins estimates margins of response for numbers of events, incidence rates, probabilities, linear predictions, and predicted values.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [ predict(statistic ...) ... ] [ options ]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>number of events; the default</td>
</tr>
<tr>
<td>ir</td>
<td>incidence rate (equivalent to predict ..., n nooffset)</td>
</tr>
<tr>
<td>pr(n)</td>
<td>probability Pr(y_j = n)</td>
</tr>
<tr>
<td>pr(a,b)</td>
<td>probability Pr(a ≤ y_j ≤ b)</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

In addition, relevant only after gnbreg are the following:

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alpha</td>
<td>predicted values of α_j</td>
</tr>
<tr>
<td>lalpha</td>
<td>predicted values of lnα_j</td>
</tr>
<tr>
<td>stdplna</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.
Remarks and examples

After \texttt{nbreg} and \texttt{gnbreg}, \texttt{predict} returns the expected number of deaths per cohort and the probability of observing the number of deaths recorded or fewer.

\begin{verbatim}
. use http://www.stata-press.com/data/r14/rod93
. nbreg deaths i.cohort, nolog

Negative binomial regression Number of obs = 21
LR chi2(2) = 0.14
Dispersion = mean
Prob > chi2 = 0.9307
Log likelihood = -108.48841 Pseudo R2 = 0.0007

    | Coef.  Std. Err.      z    P>|z|     [95% Conf. Interval]
---|---------------------------------------------------------------------
cohort |        
1960-1967 |  .0591305   .2978419   0.20  0.843    -.5246289   .642894
1968-1976 | -.0538792   .2981621  -0.18  0.857    -.6382662   .5305077
_cons     | 4.435906   .2107213   21.05  0.000     4.02289     4.848912
/lnalpha  | -1.207379  .3108622  -1.816657  0.069    -.5980999   .6447933
alpha     | .29898   .0929416    .1625683  .5498555

LR test of alpha=0: chibar2(01) = 434.62 Prob >= chibar2 = 0.000

. predict count
(option n assumed; predicted number of events)
. predict p, pr(0, deaths)
. summarize deaths count p

Variable | Obs  Mean       Std. Dev.       Min    Max
---|----------------------------------------
deaths   | 21  84.66667  48.84192       10     197
count    | 21  84.66667    4.00773       80   89.57143
p        | 21    .4991542  .2743702   .0070255   .9801285
\end{verbatim}

The expected number of deaths ranges from 80 to 90. The probability \( \Pr(y_i \leq \text{deaths}) \) ranges from 0.007 to 0.98.

Methods and formulas

In the following, we use the same notation as in \texttt{[R] nbreg}. Methods and formulas are presented under the following headings:

\begin{itemize}
\item \textit{Mean-dispersion model}
\item \textit{Constant-dispersion model}
\end{itemize}

\textbf{Mean-dispersion model}

The equation-level scores are given by

\[
\text{score}(x\beta)_j = p_j(y_j - \mu_j)
\]

\[
\text{score}(\tau)_j = -m \left\{ \frac{\alpha_j(\mu_j - y_j)}{1 + \alpha_j \mu_j} - \ln(1 + \alpha_j \mu_j) + \psi(y_j + m) - \psi(m) \right\}
\]

where \( \tau_j = \ln \alpha_j \) and \( \psi(z) \) is the digamma function.
Constant-dispersion model

The equation-level scores are given by

\[
\text{score}(x\beta)_j = m_j \{ \psi(y_j + m_j) - \psi(m_j) + \ln(p) \}
\]
\[
\text{score}(\tau)_j = y_j - (y_j + m_j)(1 - p) - \text{score}(x\beta)_j
\]

where \( \tau_j = \ln \delta_j \).

[R] nbreg — Negative binomial regression

[U] 20 Estimation and postestimation commands
**nestreg** — Nested model statistics

**Description**

*nestreg* fits nested models by sequentially adding blocks of variables and then reports comparison tests between the nested models.

**Quick start**

Fit nested (hierarchical) models sequentially, including covariates $x_1$ and $x_2$ first and then adding $x_3$ and $x_4$

```
nestreg: regress y (x1 x2) (x3 x4)
```

Also fit third model including $d_1$, $d_2$, and $d_3$

```
nestreg: regress y (x1 x2) (x3 x4) (d1 d2 d3)
```

Report table of likelihood-ratio tests instead of Wald tests comparing models

```
nestreg, lrtable: regress y (x1 x2) (x3 x4) (d1 d2 d3)
```

Fit nested models and adjust for complex survey design using *svyset* data

```
nestreg: svy: regress y (x1 x2) (x3 x4) (d1 d2 d3)
```

Note: In the above examples, *regress* could be replaced with any estimation command allowing the *nestreg* prefix.

Statistics > Other > Nested model statistics
## Syntax

### Standard estimation command syntax

```
estreg [ , options ]: command_name depvar (varlist) [ (varlist) ... ]
[ if ] [ in ] [ weight ] [ , command_options ]
```

### Survey estimation command syntax

```
estreg [ , options ]: svy [ vcetype ] [ , svy_options ]: command_name depvar
(varlist) [ (varlist) ... ] [ if ] [ in ] [ , command_options ]
```

## Options

### Reporting

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>waldtable</td>
<td>report Wald test results; the default</td>
</tr>
<tr>
<td>lrtable</td>
<td>report likelihood-ratio test results</td>
</tr>
<tr>
<td>quietly</td>
<td>suppress any output from <code>command_name</code></td>
</tr>
<tr>
<td>store(stub)</td>
<td>store nested estimation results in <code>_est_stub#</code></td>
</tr>
</tbody>
</table>

by is allowed; see [U] 11.1.10 Prefix commands.

Weights are allowed if `command_name` allows them; see [U] 11.1.6 weight.

A `varlist` in parentheses indicates that this list of variables is to be considered as a block. Each variable in a `varlist` not bound in parentheses will be treated as its own block.

All postestimation commands behave as they would after `command_name` without the `nestreg` prefix; see the postestimation manual entry for `command_name`.

## Remarks and examples

Remarks are presented under the following headings:

- Estimation commands
- Wald tests
- Likelihood-ratio tests
- Programming for `nestreg`
Estimation commands

`nestreg` removes collinear predictors and observations with missing values from the estimation sample before calling `command_name`.

The following Stata commands are supported by `nestreg`:

`betareg`, `clogit`, `cloglog`, `glm`, `intreg`, `logistic`, `logit`, `nbreg`, `ologit`, `oprobit`, `poisson`, `probit`, `qreg`, `regress`, `scobit`, `stcox`, `stcrreg`, `streg`, and `tobit`

You do not supply a `depvar` for `stcox`, `stcrreg`, or `streg`; otherwise, `depvar` is required. You must supply two `depvars` for `intreg`.

Wald tests

Use `nestreg` to test the significance of blocks of predictors, building the regression model one block at a time. Using the data from example 1 of `[R] test`, we wish to test the significance of the following predictors of birth rate: `medage`, `medagesq`, and `region` (already partitioned into four indicator variables: `reg1`, `reg2`, `reg3`, and `reg4`).
. use http://www.stata-press.com/data/r14/census4
(birth rate, median age)
. nestreg: regress brate (medage) (medagesq) (reg2-reg4)

```

`nestreg` collected the $F$ statistic for the corresponding block of predictors and the model $R^2$ statistic from each model fit.

The $F$ statistic for the first block, 164.72, is for a test of the joint significance of the first block of variables; it is simply the $F$ statistic from the regression of `brate` on `medage`. The $F$ statistic for the second block, 35.25, is for a test of the joint significance of the second block of variables in a regression of both the first and second blocks of variables. In our example, it is an $F$ test of `medagesq` in the regression of `brate` on `medage` and `medagesq`. Similarly, the third block’s $F$ statistic of 8.85 corresponds to a joint test of `reg2`, `reg3`, and `reg4` in the final regression.
## Likelihood-ratio tests

The `nestreg` command provides a simple syntax for performing likelihood-ratio tests for nested model specifications; also see `lrtest`. Using the data from example 1 of [R] `lrtest`, we wish to jointly test the significance of the following predictors of low birthweight: `age`, `lwt`, `ptl`, and `ht`.

```stata
.use http://www.stata-press.com/data/r14/lbw
(Hosmer & Lemeshow data)
.xi: nestreg, lr: logistic low (i.race smoke ui) (age lwt ptl ht)
i.race _Irace_1-3 (naturally coded; _Irace_1 omitted)
```

**Block 1: _Irace_2 _Irace_3 smoke ui**

|            | Odds Ratio | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|------------|------------|-----------|------|-----|---------------------|
| _Irace_2   | 3.052746   | 1.498087  | 2.27 | 0.023 | 1.166747 7.987382   |
| _Irace_3   | 2.922693   | 1.189229  | 2.64 | 0.008 | 1.316457 6.489285   |
| smoke      | 2.945742   | 1.101838  | 2.89 | 0.004 | 1.415167 6.131715   |
| ui         | 2.419131   | 1.047359  | 2.04 | 0.041 | 1.035459 5.651788   |
| _cons      | 0.1402209  | 0.0512295 | -5.38| 0.000 | 0.0685216 2.869447   |

**Log likelihood = -107.93404**

Pseudo R2 = 0.0801

**Block 2: age lwt ptl ht**

|            | Odds Ratio | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|------------|------------|-----------|------|-----|---------------------|
| _Irace_2   | 3.534767   | 1.860737  | 2.40 | 0.016 | 1.259736 9.918406   |
| _Irace_3   | 2.368079   | 1.039949  | 1.96 | 0.050 | 1.001356 5.600207   |
| smoke      | 2.517698   | 1.00916   | 2.30 | 0.021 | 1.147676 5.523162   |
| ui         | 2.1351     | 0.9808153 | 1.65 | 0.099 | 0.8677528 5.2534    |
| age        | 0.9732636  | 0.0354759 | -0.74| 0.457 | 0.9061578 1.045339  |
| lwt        | 0.9849634  | 0.0068217 | -2.19| 0.029 | 0.9716834 0.9984249 |
| ptl        | 1.719161   | 0.5982579 | 1.56 | 0.118 | 0.8721455 3.388787  |
| ht         | 6.249602   | 4.322408  | 2.65 | 0.008 | 1.611152 24.24199   |
| _cons      | 1.586014   | 1.910496  | 0.38 | 0.702 | 0.1496092 16.8134   |

**Log likelihood = -100.724**

Pseudo R2 = 0.1416

The estimation results from the full model are left in `e()`, so we can later use `estat` and other postestimation commands.

```stata
.estat gof
Logistic model for low, goodness-of-fit test
number of observations = 189
number of covariate patterns = 182
Pearson chisq(173) = 179.24
Prob > chi2 = 0.3567
```

<table>
<thead>
<tr>
<th>Block</th>
<th>LL</th>
<th>LR</th>
<th>df</th>
<th>Pr &gt; LR</th>
<th>AIC</th>
<th>BIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>-107.934</td>
<td>18.80</td>
<td>4</td>
<td>0.0009</td>
<td>225.8681</td>
<td>242.0768</td>
</tr>
<tr>
<td>2</td>
<td>-100.724</td>
<td>14.42</td>
<td>4</td>
<td>0.0061</td>
<td>219.448</td>
<td>248.6237</td>
</tr>
</tbody>
</table>

The estimation results from the full model are left in `e()`, so we can later use `estat` and other postestimation commands.
Programming for nestreg

If you want your user-written command (command_name) to work with nestreg, it must follow standard Stata syntax and allow the if qualifier. Furthermore, command_name must have sw or swml as a program property; see [P] program properties. If command_name has swml as a property, command_name must store the log-likelihood value in e(ll) and the model degrees of freedom in e(df_m).

Stored results

nestreg stores the following in r():

Matrices
  r(wald) matrix corresponding to the Wald table
  r(lr) matrix corresponding to the likelihood-ratio table

Acknowledgment

We thank Paul H. Bern of Syracuse University for developing the hierarchical regression command that inspired nestreg.

net — Install and manage user-written additions from the Internet

Description

net downloads and installs additions to Stata. The additions can be obtained from the Internet or from physical media. The additions can be ado-files (new commands), help files, or even datasets. Collections of files that may be installed as a group are bound together into a package.

ado manages the packages you have installed by using net. The ado command lets you list and uninstall previously installed packages.

You can also access the net and ado features by selecting Help > SJ and user-written commands; this is the recommended method to find and install additions to Stata.

Syntax

Set current location for net

```
net from directory_or_url
```

Change to a different net directory

```
net cd path_or_url
```

Change to a different net site

```
net link linkname
```

Search for installed packages

```
net search          (see [R] net search)
```

Report current net location

```
net
```

Describe a package

```
net describe pkgname [, from(directory_or_url)]
```

Set location where packages will be installed

```
net set ado dirname
```
Set location where ancillary files will be installed

    net set other dirName

Report net ‘from’, ‘ado’, and ‘other’ settings

    net query

Install ado-files and help files from a package

    net install pkgName [ , all replace force from(directory_or_url) ]

Install ancillary files from a package

    net get pkgName [ , all replace force from(directory_or_url) ]

Shortcut to access Stata Journal (SJ) net site

    net sj vol-issue [ insert ]

Shortcut to access Stata Technical Bulletin (STB) net site

    net stb issue [ insert ]

List installed packages

    ado [ , find(string) from(dirName) ]

    ado dir [ pkgid ] [ , find(string) from(dirName) ]

Describe installed packages

    ado describe [ pkgid ] [ , find(string) from(dirName) ]

Uninstall an installed package

    ado uninstall pkgid [ , from(dirName) ]

where

* pkgname is name of a package
* pkgid is name of a package
  or a number in square brackets: [#]
* dirName is a directory name
  or PLUS (default)
  or PERSONAL
  or SITE
Options

_all_ is used with _net install_ and _net get_. Typing it with either one makes the command equivalent to typing _net install_ followed by _net get_.

_replace_ is for use with _net install_ and _net get_. It specifies that the downloaded files replace existing files if any of the files already exists.

_force_ specifies that the downloaded files replace existing files if any of the files already exists, even if Stata thinks all the files are the same. _force_ implies _replace_.

_find(string)_ is for use with _ado_, _ado dir_, and _ado describe_. It specifies that the descriptions of the packages installed on your computer be searched, and that the package descriptions containing _string_ be listed.

_from(dirname_), when used with _ado_, specifies where the packages are installed. The default is _from(PLUS)_._PLUS_ is a code word that Stata understands to correspond to a particular directory on your computer that was set at installation time. On Windows computers, _PLUS_ probably means the directory _c:\ado\plus_, but it might mean something else. You can find out what it means by typing _sysdir_, but doing so is irrelevant if you use the defaults.

_from(directory_or_url_), when used with _net_, specifies the directory or URL where installable packages may be found. The directory or URL is the same as the one that would have been specified with _net from_.

Remarks and examples

For an introduction to using _net_ and _ado_, see [U] 28 Using the Internet to keep up to date. The purpose of this documentation is

- to briefly, but accurately, describe _net_ and _ado_ and all their features and
- to provide documentation to those who wish to set up their own sites to distribute additions to Stata.

Remarks are presented under the following headings:

- Definition of a package
- The purpose of the _net_ and _ado_ commands
- Content pages
- Package-description pages
- Where packages are installed
- A summary of the _net_ command
- A summary of the _ado_ command
- Relationship of _net_ and _ado_ to the point-and-click interface
- Creating your own site
- Format of content and package-description files
- Example 1
- Example 2
- Additional package directives
- SMCL in content and package-description files
- Error-free file delivery
**Definition of a package**

A **package** is a collection of files—typically, .ado and .sthlp files—that together provide a new feature in Stata. Packages contain additions that you wish had been part of Stata at the outset. For instance, the package named zz49 might add the xyz command to Stata. At a minimum, such a package would contain xyz.ado, the code to implement the new command, and xyz.sthlp, the system help to describe it. We write such additions, and so do other users.

One source of these additions is the *Stata Journal*, a printed and electronic journal with corresponding software. If you want the journal, you must subscribe, but the software is available for free from our website.

**The purpose of the net and ado commands**

The **net** command makes it easy to distribute and install packages. The goal is to get you quickly to a package-description page that summarizes the addition, for example,

```
. net describe rte_stat, from(http://www.wemakeitupaswego.edu/faculty/sgazer/)
```

<table>
<thead>
<tr>
<th>package rte_stat from <a href="http://www.wemakeitupaswego.edu/faculty/sgazer/">http://www.wemakeitupaswego.edu/faculty/sgazer/</a></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>TITLE</strong></td>
</tr>
<tr>
<td>rte_stat. The robust-to-everything statistic; update.</td>
</tr>
<tr>
<td><strong>DESCRIPTION/AUTHOR(S)</strong></td>
</tr>
<tr>
<td>S. Gazer, Dept. of Applied Theoretical Mathematics, WMIUAWG Univ.</td>
</tr>
<tr>
<td>Aleph-0 100% confidence intervals proved too conservative for some applications; Aleph-1 confidence intervals have been substituted.</td>
</tr>
<tr>
<td>The new robust-to-everything supplants the previous robust-to-everything-conceivable statistic. See &quot;Inference in the absence of data&quot; (forthcoming). After installation, see help rte.</td>
</tr>
<tr>
<td><strong>INSTALLATION FILES</strong></td>
</tr>
<tr>
<td>(type net install rte_stat)</td>
</tr>
<tr>
<td>rte.ado</td>
</tr>
<tr>
<td>rte.sthlp</td>
</tr>
<tr>
<td>nullset.ado</td>
</tr>
<tr>
<td>random.ado</td>
</tr>
</tbody>
</table>

If you decide that the addition might prove useful, **net** makes the installation easy:

```
. net install rte_stat
```

checking **rte_stat** consistency and verifying not already installed...

installing into c:\ado\plus\ ...

installation complete.

The **ado** command helps you manage packages installed with **net**. Perhaps you remember that you installed a package that calculates the robust-to-everything statistic, but you cannot remember the command’s name. You could use **ado** to search what you have previously installed for the **rte** command,

```
. ado
```

STB-56 sg145. Scalar measures of fit for regression models.

(output omitted)

rte_stat. The robust-to-everything statistic; update.

(output omitted)

SJ7-1 st0119. Rasch analysis
or you might type

```
. ado, find("robust-to-everything")

   `rte_stat'. The robust-to-everything statistic; update.
```

Perhaps you decide that `rte', despite the author’s claims, is not worth the disk space it occupies. You can use `ado' to erase it:

```
. ado uninstall `rte_stat'

package `rte_stat' from http://www.wemakeitupaswego.edu/faculty/sgazer
   `rte_stat'. The robust-to-everything statistic; update.
   (package uninstalled)
```

`ado uninstall' is easier than erasing the files by hand because `ado uninstall' erases every file associated with the package, and, moreover, `ado' knows where on your computer `rte_stat' is installed; you would have to hunt for these files.

## Content pages

There are two types of pages displayed by `net': content pages and package-description pages. When you type `net from', `net cd', `net link', or `net' without arguments, Stata goes to the specified place and displays the content page:

```
. net from http://www.stata.com

http://www.stata.com/
   StataCorp

Welcome to StataCorp.
Below we provide links to sites providing additions to Stata, including the Stata Journal, STB, and Statalist. These are NOT THE OFFICIAL UPDATES; you fetch and install the official updates by typing `-update-'.

PLACES you could `-net link-' to:
   sj
      The Stata Journal

DIRECTORIES you could `-net cd-' to:
   stb
      materials published in the Stata Technical Bulletin
   users
      materials written by various people, including StataCorp employees
   meetings
      software packages from Stata Users Group meetings
   links
      links to other locations providing additions to Stata
```

A content page tells you about other content pages and package-description pages. The example above lists other content pages only. Below we follow one of the links for the `Stata Journal':

```
```
The Stata Journal is a refereed, quarterly journal containing articles of interest to Stata users. For more details and subscription information, visit the Stata Journal website at http://www.stata-journal.com.

PLACES you could \texttt{-net link-} to:
\begin{itemize}
  \item stata \quad \text{StataCorp website}
\end{itemize}

DIRECTORIES you could \texttt{-net cd-} to:
\begin{itemize}
  \item production \quad \text{Files for authors of the Stata Journal}
  \item software \quad \text{Software associated with Stata Journal articles}
\end{itemize}

http://www.stata-journal.com/software/

The Stata Journal

PLACES you could \texttt{-net link-} to:
\begin{itemize}
  \item stata \quad \text{StataCorp website}
  \item stb \quad \text{Stata Technical Bulletin (STB) software archive}
\end{itemize}

DIRECTORIES you could \texttt{-net cd-} to:
\begin{itemize}
  \item sj7-1 \quad \text{volume 7, issue 1}
\end{itemize}

http://www.stata-journal.com/software/sj7-1/

Stata Journal volume 7, issue 1

DIRECTORIES you could \texttt{-net cd-} to:
\begin{itemize}
  \item .. \quad \text{Other Stata Journals}
\end{itemize}

PACKAGES you could \texttt{-net describe-}:
\begin{itemize}
  \item dm0027 \quad \text{File filtering in Stata: handling complex data formats and navigating log files efficiently}
  \item st0119 \quad \text{Rasch analysis}
  \item st0120 \quad \text{Multivariable regression spline models}
  \item st0121 \quad \text{mhbounds - Sensitivity Analysis for Average Treatment Effects}
\end{itemize}

\texttt{dm0027, st0119, \ldots, st0121} are links to package-description pages.

1. When you type \texttt{net from}, you follow that with a location to display the location’s content page.
   \begin{itemize}
   \item a. The location could be a URL, such as \url{http://www.stata.com}. The content page at that location would then be listed.
   \item b. The location could be \texttt{e:} on a Windows computer or a mounted volume on a Mac computer. The content page on that source would be listed. That would work if you had special media obtained from StataCorp or special media prepared by another user.
   \item c. The location could even be a directory on your computer, but that would work only if that directory contained the right kind of files.
   \end{itemize}
2. Once you have specified a location, typing `net cd` will take you into subdirectories of that location, if there are any. Typing

```
.net from http://www.stata-journal.com
.net cd software
```

is equivalent to typing

```
.net from http://www.stata-journal.com/software
```

Typing `net cd` displays the content page from that location.

3. Typing `net` without arguments redisplays the current content page, which is the content page last displayed.

4. `net link` is similar to `net cd` in that the result is to change the location, but rather than changing to subdirectories of the current location, `net link` jumps to another location:

```
.net from http://www.stata-journal.com
```

http://www.stata-journal.com/

The Stata Journal

The Stata Journal is a refereed, quarterly journal containing articles of interest to Stata users. For more details and subscription information, visit the Stata Journal website at http://www.stata-journal.com.

PLACES you could `-net link-` to:

- stata  StataCorp website

DIRECTORIES you could `-net cd-` to:

- production  Files for authors of the Stata Journal
- software  Software associated with Stata Journal articles

Typing `net link stata` would jump to http://www.stata.com:

```
.net link stata
```

http://www.stata.com/

StataCorp

Welcome to StataCorp.

(output omitted)

**Package-description pages**

Package-description pages describe what could be installed:
A package-description page describes the package and tells you how to install the component files. Package-description pages potentially describe two types of files:

1. Installation files: files that you type `net install` to install and that are required to make the addition work.
2. Ancillary files: additional files that you might want to install—you type `net get` to install them—but that you can ignore. Ancillary files are typically datasets that are useful for demonstration purposes. Ancillary files are not really installed in the sense of being copied to an official place for use by Stata itself. They are merely copied into the current directory so that you may use them if you wish.

You install the official files by typing `net install` followed by the package name. For example, to install `st0119`, you would type

```
. net install st0119
checking st0119 consistency and verifying not already installed...
installing into c:\ado\plus\ ...
installation complete.
```

You get the ancillary files—if there are any and if you want them—by typing `net get` followed by the package name:
. net get st0119
checking st0119 consistency and verifying not already installed...
copying into current directory...
copying data.dta
copying outrasch.do
ancillary files successfully copied.

Most users ignore the ancillary files.

Once you have installed a package—by typing net install—use ado to redisplay the package-description page whenever you wish:

. ado describe st0119

---

TITLE
SJ7-1 st0119. Rasch analysis

INSTALLED ON
24 Feb 2015

---

The package-description page shown by ado includes the location from which we got the package and when we installed it. It does not mention the ancillary files that were originally part of this package because they are not tracked by ado.

Where packages are installed

Packages should be installed in PLUS or SITE, which are code words that Stata understands and that correspond to some real directories on your computer. Typing sysdir will tell you where these are, if you care.

. sysdir
STATA: C:\Program Files\Stata14\nBASE: C:\Program Files\Stata14\ado\base\
SITE: C:\Program Files\Stata14\ado\site\
PLUS: c:\ado\plus\nPERSONAL: c:\ado\personal\nOLDPLACE: c:\ado\

If you type sysdir, you may obtain different results.
By default, `net` installs in the PLUS directory, and ado tells you about what is installed there. If you are on a multiple-user system, you may wish to install some packages in the SITE directory. This way, they will be available to other Stata users. To do that, before using `net install`, type

```
.net set ado SITE
```

and when reviewing what is installed or removing packages, redirect ado to that directory:

```
ado ..., from(SITE)
```

In both cases, you type SITE because Stata will understand that SITE means the site ado-directory as defined by `sysdir`. To install into SITE, you must have write access to that directory.

If you reset where `net` installs and then, in the same session, wish to install into your private ado-directory, type

```
.net set ado PLUS
```

That is how things were originally. If you are confused as to where you are, type `net query`.

### A summary of the net command

The `net` command displays content pages and package-description pages. Such pages are provided over the Internet, and most users get them there. We recommend that you start at `http://www.stata.com` and work out from there. We also recommend using `net search` to find packages of interest to you; see `[R] net search`.

- `net from` moves you to a location and displays the content page.
- `net cd` and `net link` change from your current location to other locations. `net cd` enters subdirectories of the original location. `net link` jumps from one location to another, depending on the code on the content page.
- `net describe` lists a package-description page. Packages are named, and you type `net describe pkgname`.
- `net install` installs a package into your copy of Stata. `net get` copies any additional files (ancillary files) to your current directory.
- `net sj` and `net stb` simplify loading files from the *Stata Journal* and its predecessor, the *Stata Technical Bulletin*.
  - `net sj vol-issue` is a synonym for typing
  - whereas
    - `net sj vol-issue insert` is a synonym for typing
      - `net describe insert`
- `net set` controls where `net` installs files. By default, `net` installs in the PLUS directory; see `[P] sysdir`. `net set ado SITE` would cause subsequent `net` commands to install in the SITE directory. `net set other` sets where ancillary files, such as `.dta` files, are installed. The default is the current directory.
- `net query` displays the current `net from`, `net set ado`, and `net set other` settings.
A summary of the ado command

The ado command lists the package descriptions of previously installed packages.

Typing ado without arguments is the same as typing ado dir. Both list the names and titles of the packages you have installed.

ado describe lists full package-description pages.

ado uninstall removes packages from your computer.

Because you can install packages from a variety of sources, the package names may not always be unique. Thus the packages installed on your computer are numbered sequentially, and you may refer to them by name or by number. For instance, say that you wanted to get rid of the robust-to-everything statistic command you installed. Type

```
. ado, find("robust-to-everything")
```

**rte_stat. The robust-to-everything statistic; update.**

You could then type

```
. ado uninstall rte_stat
```

or

```
. ado uninstall [15]
```

Typing ado uninstall rte_stat would work only if the name rte_stat were unique; otherwise, ado would refuse, and you would have to type the number.

The find() option is allowed with ado dir and ado describe. It searches the package description for the word or phrase you specify, ignoring case (alpha matches Alpha). The complete package description is searched, including the author’s name and the name of the files. Thus if rte was the name of a command that you wanted to eliminate, but you could not remember the name of the package, you could type

```
. ado, find(rte)
```

**rte_stat. The robust-to-everything statistic; update.**

Relationship of net and ado to the point-and-click interface

Users may instead select Help > SJ and user-written commands. There are advantages and disadvantages:

1. Flipping through content and package-description pages is easier; it is much like a browser. See [GS] 19 Updating and extending Stata—Internet functionality (GSM, GSU, or GSW).

2. When browsing a product-description page, note that the .sthlp files are highlighted. You may click on .sthlp files to review them before installing the package.

3. You may not redirect from where ado searches for files.
Creating your own site

Users who wish to share content with the Stata community often do so via the Statistical Software Components (SSC) archive. See [R] ssc and also see http://repec.org/bocode/s/sscsubmit.html.

The rest of this entry concerns how to create your own site to distribute additions to Stata. The idea is that you have written additions for use with Stata—say, xyz.ado and xyz.sthlp—and you wish to put them out so that coworkers or researchers at other institutions can easily install them. Or, perhaps you just have a dataset that you and others want to share.

In any case, all you need is a webpage. You place the files that you want to distribute on your webpage (or in a subdirectory), and you add two more files—a content file and a package-description file—and you are done.

Format of content and package-description files

The content file describes the content page. It must be named stata.toc:

```plaintext
begin stata.toc

OFF

* lines starting with * are comments; they are ignored
* blank lines are ignored, too
* v indicates version—specify v 3, which is the current version of .toc files
v 3
* d lines display description text
* the first d line is the title, and the remaining ones are text
* blank d lines display a blank line
d title
d text
d
d
* l lines display links
l word-to-show path-or-url [description]
l word-to-show path-or-url [description]
...
* t lines display other directories within the site
t path [description]
t path [description]
...
* p lines display packages
p pkgname [description]
p pkgname [description]
...

end stata.toc
```

Package files describe packages and are named pkgname.pkg:
Net — Install and manage user-written additions from the Internet

begin pkgname.pkg

* lines starting with * are comments; they are ignored
* blank lines are ignored, too
* v indicates version—specify v 3, which is the current version of .toc files

v 3
* d lines display package description text
* the first d line is the title, and the remaining ones are text
* blank d lines display a blank line
d title
d text
d Distribution-Date: date
d text
d
...
* f identifies the component files
f [path/]/filename [description]
f [path/]/filename [description]
...
* e line is optional; it means stop reading
e

end pkgname.pkg

Note the Distribution-Date description line. This line is optional but recommended. Stata can look for updates to user-written programs with the adoupdate command if the package files from which those programs were installed contain a Distribution-Date description line.

Example 1

Say that we want the user to see the following:

Say that we want the user to see the following:

. net from http://www.university.edu/~me

http://www.university.edu/~me
Chris Farrar, Uni University

PACKAGES you could -net describe-:

package xyz from http://www.university.edu/~me

. net describe xyz

TITLE

xyz. interval-truncated survival.

DESCRIPTION/AUTHOR(S)

C. Farrar, Uni University.

INSTALLATION FILES

(type net install xyz)
xyz.ado
xyz.sthlp

ANCILLARY FILES

(type net get xyz)
sample.dta

The files needed to do this would be

begin stata.toc

v 3
d Chris Farrar, Uni University
p xyz interval-truncated survival

end stata.toc
On his homepage, Chris would place the following files:

- `stata.toc` (shown above)
- `xyz.pkg` (shown above)
- `xyz.ado` file to be delivered (for use by `net install`)
- `xyz.sthlp` file to be delivered (for use by `net install`)
- `sample.dta` file to be delivered (for use by `net get`)

Chris does nothing to distinguish ancillary files from installation files.

**Example 2**

S. Gazer wants to create a more complex site:

```
. net from http://www.wemakeitupaswego.edu/faculty/sgazer
```

http://www.wemakeitupaswego.edu/faculty/sgazer

**Data-free inference materials**

S. Gazer, Department of Applied Theoretical Mathematics

Also see my homepage for the preprint of "Irrefutable inference".

PLACES you could **net link** to:

- `stata` StataCorp website

DIRECTORY you could **net cd** to:

- `ir` irrefutable inference programs (work in progress)

PACKAGES you could **net describe**:

- `rtec` Robust-to-everything-conceivable statistic
- `rte` Robust-to-everything statistic
. net describe rte

package rte from http://www.wemakeitupaswego.edu/faculty/sgazer/

TITLE
rte. The robust-to-everything statistic; update.

DESCRIPTION/AUTHOR(S)
S. Gazer, Dept. of Applied Theoretical Mathematics, WMIUAWG Univ.
Aleph-0 100% confidence intervals proved too conservative for some applications; Aleph-1 confidence intervals have been substituted. The new robust-to-everything supplants the previous robust-to-everything-conceivable statistic. See "Inference in the absence of data" (forthcoming). After installation, see help rte.

Distribution-Date: 20150320
Support: email sgazer@wemakeitupaswego.edu

INSTALLATION FILES
(type net install rte_stat)
rte.ado
rte.sthlp
nullset.ado
random.ado

ANCILLARY FILES
(type net get rte_stat)
empty.dta

The files needed to do this would be

---begin stata.toc---
v 3
d Data-free inference materials
d S. Gazer, Department of Applied Theoretical Mathematics

d
d Support: email sgazer@wemakeitupaswego.edu
f rte.ado
f rte.sthlp
f nullset.ado
f random.ado
f empty.dta
---end rte.pkg---
On his homepage, Mr. Gazer would place the following files:

- `stata.toc`  
  (shown above)
- `rte.pkg`  
  (shown above)
- `rte.ado`  
  (file to be delivered)
- `rte.sthlp`  
  (file to be delivered)
- `nullset.ado`  
  (file to be delivered)
- `random.ado`  
  (file to be delivered)
- `empty.dta`  
  (file to be delivered)
- `rtec.pkg`  
  the other package referred to in `stata.toc`
- `rtec.ado`  
  the corresponding files to be delivered
- `rtec.sthlp`  

- `ir/stata.toc`  
  the contents file for when the user types `net cd ir`
- `ir/...`  
  whatever other `.pkg` files are referred to
- `ir/...`  
  whatever other files are to be delivered

If Mr. Gazer later updated the `rte` package, he could change the Distribution-Date description line in his package. Then, if someone who had previously installed the `rte` packaged wanted to obtain the latest version, that person could use the `adoupdate` command; see [R] adoupdate.

For complex sites, a different structure may prove more convenient:

- `stata.toc`  
  (shown above)
- `rte.pkg`  
  (shown above)
- `rtec.pkg`  
  the other package referred to in `stata.toc`
- `rte/`  
  directory containing `rte` files to be delivered:
  - `rte/rte.ado`  
    (file to be delivered)
  - `rte/rte.sthlp`  
    (file to be delivered)
  - `rte/nullset.ado`  
    (file to be delivered)
  - `rte/random.ado`  
    (file to be delivered)
  - `rte/empty.dta`  
    (file to be delivered)
- `rtec/`  
  directory containing `rtec` files to be delivered:
  - `rtec/...`  
    (files to be delivered)
- `ir/stata.toc`  
  the contents file for when the user types `net cd ir`
- `ir/*/pkg`  
  whatever other package files are referred to
- `ir/*/...`  
  whatever other files are to be delivered

If you prefer this structure, it is simply a matter of changing the bottom of the `rte.pkg` from

```
  f rte.ado
  f rte.sthlp
  f nullset.ado
  f random.ado
  f empty.dta
```

to

```
  f rte/rte.ado
  f rte/rte.sthlp
  f rte/nullset.ado
  f rte/random.ado
  f rte/empty.dta
```

In writing paths and files, the directory separator forward slash (`/`) is used, regardless of operating system, because this is what the Internet uses.

It does not matter whether the files you put out are in Windows, Mac, or Unix format (how lines end is recorded differently). When Stata reads the files over the Internet, it will figure out the file format on its own and will automatically translate the files to what is appropriate for the receiver.
Additional package directives

F filename is similar to f filename, except that, when the file is installed, it will always be copied to the system directories (and not the current directory).

With f filename, the file is installed into a directory according to the file’s suffix. For instance, xyz.ado would be installed in the system directories, whereas xyz.dta would be installed in the current directory.

Coding F xyz.ado would have the same result as coding f xyz.ado.

Coding F xyz.dta, however, would state that xyz.dta is to be installed in the system directories.

g platformname filename is also a variation on f filename. It specifies that the file be installed only if the user’s operating system is of type platformname; otherwise, the file is ignored. The platform names are WIN64A (64-bit x86-64) and WIN (32-bit x86) for Windows; MACINTEL64 (64-bit Intel, GUI), OSX.X8664 (64-bit Intel, console), MACINTEL (32-bit Intel, GUI), and OSX.X86 (32-bit Intel, console) for Mac; and LINUX64 (64-bit x86-64) and LINUX (32-bit x86) for Unix.

G platformname filename is a variation on F filename. The file, if not ignored, is to be installed in the system directories.

g platformname filename1 filename2 is a more detailed version of g platformname filename. In this case, filename1 is the name of the file on the server (the file to be copied), and filename2 is to be the name of the file on the user’s system; for example, you might code

    g WIN mydll.forwin mydll.plugin
    g LINUX mydll.forlinux mydll.plugin

When you specify one filename, the result is the same as specifying two identical filenames.

G platformname filename1 filename2 is the install-in-system-directories version of g platformname filename1 filename2.

h filename asserts that filename must be loaded, or this package is not to be installed; for example, you might code

    g WIN mydll.forwin mydll.plugin
    g LINUX mydll.forlinux mydll.plugin
    h mydll.plugin

if you were offering the plugin mydll.plugin for Windows and Linux only.

SMCL in content and package-description files

The text listed on the second and subsequent d lines in both stata.toc and pkgname.pkg may contain SMCL as long as you include v 3; see [P] smcl.

Thus, in rte.pkg, S. Gazer coded the third line as

    d {bf:S. Gazer, Dept. of Applied Theoretical Mathematics, WMIUAWG Univ.}

Error-free file delivery

Most people transport files over the Internet and never worry about the file being corrupted in the process because corruption rarely occurs. If, however, the files must be delivered perfectly or not at all, you can include checksum files in the directory.
For instance, say that `big.dta` is included in your package and that it must be sent perfectly. First, use Stata to make the checksum file for `big.dta`:

```
. checksum big.dta, save
```

That command creates a small file called `big.sum`; see [D] checksum. Then copy both `big.dta` and `big.sum` to your homepage. If `set checksum` is on (the default is off), whenever Stata reads `filename.whatever` over the net, it also looks for `filename.sum`. If it finds such a file, it uses the information recorded in it to verify that what was copied was error free.

If you do this, be cautious. If you put `big.dta` and `big.sum` on your homepage and then later change `big.dta` without changing `big.sum`, people will think that there are transmission errors when they try to download `big.dta`.

net search — Search the Internet for installable packages

Description

net search searches the Internet for user-written additions to Stata, including, but not limited to, user-written additions published in the *Stata Journal* (SJ) and in the *Stata Technical Bulletin* (STB). net search lists the available additions that contain the specified keywords.

The user-written materials found are available for immediate download by using the net command or by clicking on the link.

In addition to typing net search, you may select Help > Search... and choose Search net resources. This is the recommended way to search for user-written additions to Stata.

Quick start

Search user-written commands for all terms word1, word2, and word3

    net search word1 word2 word3

As above, but search for any term

    net search word1 word2 word3, or

Search Internet sources other than the *Stata Journal* and the *Stata Technical Bulletin*

    net search word1 word2 word3, nosj
Syntax

```
net search  word  [word  ...]  [,  options]
```

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>or</td>
<td>list packages that contain any of the keywords; default is all</td>
</tr>
<tr>
<td>nosj</td>
<td>search non-SJ and non-STB sources</td>

<td>make return code 111 instead of 0 when no matches found</td>
</tr>
</tbody>
</table>

Options

or is relevant only when multiple keywords are specified. By default, net search lists only packages that include all the keywords. or changes the command to list packages that contain any of the keywords.

nosj specifies that net search not list matches that were published in the SJ or in the STB.

tocpkg, toc, and pkg determine what is searched. tocpkg is the default, meaning that both tables of contents (tocs) and packages (pkgs) are searched. toc restricts the search to tables of contents. pkg restricts the search to packages.

everywhere and filenames determine where in packages net search looks for keywords. The default is everywhere. filenames restricts net search to search for matches only in the filenames associated with a package. Specifying everywhere implies pkg.

errnone is a programmer’s option that causes the return code to be 111 instead of 0 when no matches are found.
Remarks and examples

`net search` searches the Internet for user-written additions to Stata. If you want to search the Stata documentation for a particular topic, command, or author, see `[R] search`. `net search word [word ...]` (without options) is equivalent to typing `search word [word ...], net.`

Remarks are presented under the following headings:

- Topic searches
- Author searches
- Command searches
- Where does `net search` look?
- How does `net search` work?

**Topic searches**

**Example: Find what is available about random effects**

```
.net search random effect
```

Comments:

- It is best to search using the singular form of a word. `net search random effect` will find both “random effect” and “random effects”.
- `net search random effect` will also find “random-effect” because `net search` performs a string search and not a word search.
- `net search random effect` lists all packages containing the words “random” and “effect”, not necessarily used together.
- If you wanted all packages containing the word “random” or the word “effect”, you would type `net search random effect, or`.

**Author searches**

**Example: Find what is available by author Jeroen Weesie**

```
.net search weesie
```

Comments:

- You could type `net search jeroen weesie`, but that might list fewer results because sometimes the last name is used without the first.
- You could type `net search Weesie`, but it would not matter. Capitalization is ignored in the search.

**Example: Find what is available by Jeroen Weesie, excluding SJ and STB materials**

```
.net search weesie, nosj
```

- The SJ and the STB tend to dominate search results because so much has been published in them. If you know that what you are looking for is not in the SJ or in the STB, specifying the `nosj` option will narrow the search.
- `net search weesie` lists everything that `net search weesie, nosj` lists, and more. If you just type `net search weesie`, look down the list. SJ and STB materials are listed first, and non-SJ and non-STB materials are listed last.
Command searches

Example: Find the user-written command kursus

. net search kursus, file

- You could just type `net search kursus`, and that will list everything `net search kursus`, `file` lists, and more. Because you know `kursus` is a command, however, there must be a `kursus.ado` file associated with the package. Typing `net search kursus, file` narrows the search.

- You could also type `net search kursus.ado, file` to narrow the search even more.

Where does net search look?

`net search` begins by looking at `http://www.stata.com`, but then follows every link, which takes it to other places, and then follows every link again, which takes it to even more places, and so on.

Authors: Please let us know if you have a site that we should include in our search by sending an email to webmaster@stata.com. We will then link to your site from ours to ensure that `net search` finds your materials. That is not strictly necessary, however, as long as your site is directly or indirectly linked from some site that is linked to ours.

How does net search work?
Our website maintains a database of Stata resources. When you use `net search`, it contacts http://www.stata.com with your request, http://www.stata.com searches its database, and Stata returns the results to you.

Another part of the system is called the crawler, which searches the web for new Stata resources to add to the `net search` database and verifies that the resources already found are still available. When a new resource becomes available, the crawler takes about 2 days to add it to the database, and, similarly, if a resource disappears, the crawler takes roughly 2 days to remove it from the database.

Description

Several commands (for example, `net`, `news`, and `update`) are designed specifically for use over the Internet. Many other Stata commands that read a file (for example, `copy`, `type`, and `use`) can also read directly from a URL. All of these commands will usually work without your ever needing to concern yourself with the `set` commands discussed here. These `set` commands provide control over network system parameters.

If you experience problems when using Stata’s network features, ask your system administrator if your site uses a proxy. A proxy is a server between your computer and the rest of the Internet, and your computer may need to communicate with other computers on the Internet through this proxy. If your site uses a proxy, your system administrator can provide you with its host name and the port your computer can use to communicate with it. If your site’s proxy requires you to log in to it before it will respond, your system administrator will provide you with a user ID and password.

`set httpproxyhost` sets the name of the host to be used as a proxy server. `set httpproxyport` sets the port number. `set httpproxy` turns on or off the use of a proxy server, leaving the proxy host name and port intact, even when not in use.

Under the Mac and Windows operating systems, when you `set httpproxy on`, Stata will attempt to obtain the values of `httpproxyhost` and `httpproxyport` from the operating system if they have not been previously set. `set httpproxy on, init` attempts to obtain these values from the operating system, even if they have been previously set.

If the proxy requires authorization (user ID and password), set authorization on via `set httpproxyauth on`. The proxy user and proxy password must also be set to the appropriate user ID and password by using `set httpproxyuser` and `set httpproxypw`.

Stata remembers the various proxy settings between sessions and does not need a `permanently` option.

`set timeout1` changes the time limit in seconds that Stata imposes for establishing the initial connection with a remote host. The default value is 30. `set timeout2` changes the time limit in seconds that Stata imposes for subsequent data transfer with the host. The default value is 180. If these time limits are exceeded, a “connection timed out” message and error code 2 are produced. You should seldom need to change these settings.

Syntax

Turn on or off the use of a proxy server

```
set httpproxy {on | off} [, init]
```

Set proxy host name

```
set httpproxyhost ["name"]
```

1670
Set the proxy port number

```
set httpproxyport #
```

Turn on or off proxy authorization

```
set httpproxyauth {on | off}
```

Set proxy authorization user ID

```
set httpproxyuser "name"
```

Set proxy authorization password

```
set httpproxypw "password"
```

Set time limit for establishing initial connection

```
set timeout1 #seconds [, permanently]
```

Set time limit for data transfer

```
set timeout2 #seconds [, permanently]
```

Options

- `init` specifies that `set httpproxy` on attempts to initialize `httpproxyhost` and `httpproxyport` from the operating system (Mac and Windows only).
- `permanently` specifies that, in addition to making the change right now, the `timeout1` and `timeout2` settings be remembered and become the default setting when you invoke Stata.

The various `httpproxy` settings do not have a `permanently` option because `permanently` is implied.

Remarks and examples

1. remote connection failed r(677);

If you see

```
remote connection failed
r(677);
```

then you asked for something to be done over the web, and Stata tried but could not contact the specified host. Stata was able to talk over the network and look up the host but was not able to establish a connection to that host. Perhaps the host is down; try again later.

If all your web accesses result in this message, then perhaps your network connection is through a proxy server. If it is, then you must tell Stata.
Contact your system administrator. Ask for the name and port of the “HTTP proxy server”. Say that you are told

HTTP proxy server: jupiter.myuni.edu
port number: 8080

In Stata, type

. set httpproxyhost jupiter.myuni.edu
. set httpproxyport 8080
. set httpproxy on

Your web accesses should then work.

2. connection timed out r(2); If you see

connection timed out
r(2);

then an Internet connection has timed out. This can happen when
a. the connection between you and the host is slow, or
b. the connection between you and the host has disappeared, and so it eventually “timed out”.

For (b), wait a while (say, 5 minutes) and try again (sometimes pieces of the Internet can break for up to a day, but that is rare). For (a), you can reset the limits for what constitutes “timed out”. There are two numbers to set.

The time to establish the initial connection is timeout1. By default, Stata waits 30 seconds before declaring a timeout. You can change the limit:

. set timeout1 #seconds

You might try doubling the usual limit and specify 60; #seconds must be between 1 and 32,000.

The time to retrieve data from an open connection is timeout2. By default, Stata waits 180 seconds (3 minutes) before declaring a timeout. To change the limit, type

. set timeout2 #seconds

You might try doubling the usual limit and specify 360; #seconds must be between 1 and 32,000.

[U] 28 Using the Internet to keep up to date
Description

`nl` fits an arbitrary nonlinear regression function by least squares. With the interactive version of the command, you enter the function directly on the command line or in the dialog box by using a substitutable expression. If you have a function that you use regularly, you can write a substitutable expression program and use the second syntax to avoid having to reenter the function every time. The function evaluator program version gives you the most flexibility in exchange for increased complexity; with this version, your program is given a vector of parameters and a variable list, and your program computes the regression function.

When you write a substitutable expression program or function evaluator program, the first two letters of the name must be `nl`. `sexp_prog` and `func_prog` refer to the name of the program without the first two letters. For example, if you wrote a function evaluator program named `nlregss`, you would type `nl regss @`... to estimate the parameters.

Quick start

Linear model of $y$ with parameters $b0$ for the constant and $b1$ for $x1$

```
nl (y = {b0} + {b1}*x1)
```

Add the `variables()` option to allow for missing values of $y$ and $x1$

```
nl (y = {b0} + {b1}*x1), variables(y x1)
```

As above, but specify starting values

```
nl (y = {b0=.5} + {b1=2}*x1), variables(y x1)
```

Add variables $x2$ and $x3$ and parameters $b2$ and $b3$

```
nl (y = {b0} + {b1}*x1 + {b2}*x2 + {b3}*x3), variables(y x1 x2 x3)
```

Same as above, but use `{xb:}` to specify a linear combination of variables

```
nl (y = {b0=.5} + {xb:x1 x2 x3}), variables(y x1 x2 x3)
```

An exponential model

```
nl (y = {b0} + {b1}*{b2}^x1), variables(y x1)
```

Same as above, but use `nl`’s built-in function `exp3` to specify the model

```
nl exp3: y x1, variables(y x1)
```

Menu

Statistics > Linear models and related > Nonlinear least squares estimation
Syntax

Interactive version

```
nl (depvar = <sexp>) [ if ] [ in ] [ weight ] [, options]
```

Programmed substitutable expression version

```
nl sexp_prog : depvar [ varlist ] [ if ] [ in ] [ weight ] [, options]
```

Function evaluator program version

```
nl func_prog @ depvar [ varlist ] [ if ] [ in ] [ weight ],
   { parameters(namelist) | nparameters(#) } [ options ]
```

where

- `depvar` is the dependent variable;
- `<sexp>` is a substitutable expression;
- `sexp_prog` is a substitutable expression program; and
- `func_prog` is a function evaluator program.

* For function evaluator program version, you must specify `parameters(namelist)` or `nparameters(#)`, or both.
bootstrap, by, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
aweights are not allowed with the jackknife prefix; see [R] jackknife.
`vce()`, `leave`, and weights are not allowed with the svy prefix; see [SVY] svy.
aweights, fweights, and iweights are allowed; see [U] 11.1.6 weight.
`coeflegend` does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

### Options

`variables(varlist)` specifies the variables in the model. `nl` ignores observations for which any of these variables have missing values. If you do not specify `variables()`, then `nl` issues an error message with return code 480 if the estimation sample contains any missing values.
\textbf{initial}(\textit{initial \_values}) specifies the initial values to begin the estimation. You can specify a $1 \times k$ matrix, where $k$ is the number of parameters in the model, or you can specify a parameter name, its initial value, another parameter name, its initial value, and so on. For example, to initialize alpha to 1.23 and delta to 4.57, you would type

\begin{verbatim}
  n1 \ldots, initial(alpha 1.23 delta 4.57) \ldots
\end{verbatim}

Initial values declared using this option override any that are declared within substitutable expressions. If you specify a parameter that does not appear in your model, \texttt{n1} exits with error code 480. If you specify a matrix, the values must be in the same order that the parameters are declared in your model. \texttt{n1} ignores the row and column names of the matrix.

\textbf{parameters}(\textit{namelist}) specifies the names of the parameters in the model. The names of the parameters must adhere to the naming conventions of Stata’s variables; see \texttt{U 11.3 Naming conventions}. If you specify both \texttt{parameters()} and \texttt{nparameters()}, the number of names in the former must match the number specified in the latter; if not, \texttt{n1} issues an error message with return code 198.

\textbf{nparameters}(\textit{\#}) specifies the number of parameters in the model. If you do not specify names with the \texttt{parameters()} option, \texttt{n1} names them b1, b2, \ldots, b\#. If you specify both \texttt{parameters()} and \texttt{nparameters()}, the number of names in the former must match the number specified in the latter; if not, \texttt{n1} issues an error message with return code 198.

\textit{sexp \_options} refer to any options allowed by your \texttt{sexp\_prog}.

\textit{func \_options} refer to any options allowed by your \texttt{func\_prog}.

---

\textbf{Model 2}

\texttt{lnlsq(\#)} fits the model by using log least-squares, which we define as least squares with shifted lognormal errors. In other words, $\ln(\text{depvar} - \#)$ is assumed to be normally distributed. Sums of squares and deviance are adjusted to the same scale as \texttt{depvar}.

\textbf{noconstant} indicates that the function does not include a constant term. This option is generally not needed, even if there is no constant term in the model, unless the coefficient of variation (over observations) of the partial derivative of the function with respect to a parameter is less than \texttt{eps()} and that parameter is not a constant term.

\textbf{hasconstant}(\textit{name}) indicates that parameter \textit{name} be treated as the constant term in the model and that \texttt{n1} should not use its default algorithm to find a constant term. As with \texttt{noconstant}, this option is seldom used.

\textbf{SE/Robust}

\textbf{vce}(\textit{vcetype}) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (\texttt{gnr}), that are robust to some kinds of misspecification (\texttt{robust}), that allow for intragroup correlation (\texttt{cluster clustvar}), and that use bootstrap or jackknife methods (\texttt{bootstrap}, \texttt{jackknife}); see \texttt{R vce \_option}.

\texttt{vce(gnr)}, the default, uses the conventionally derived variance estimator for nonlinear models fit using Gauss–Newton regression.

\texttt{n1} also allows the following:

\textbf{vce}(\texttt{hac kernel [\#]}) specifies that a heteroskedasticity- and autocorrelation-consistent (HAC) variance estimate be used. HAC refers to the general form for combining weighted matrices to form the variance estimate. There are three kernels available for \texttt{n1}:

\begin{verbatim}
  nw \_east | gallant | anderson
\end{verbatim}
# specifies the number of lags. If # is not specified, \( N - 2 \) is assumed.

\texttt{vce(hac kernel [#])} is not allowed if weights are specified.

\texttt{vce(hc2)} and \texttt{vce(hc3)} specify alternative bias corrections for the robust variance calculation. \texttt{vce(hc2)} and \texttt{vce(hc3)} may not be specified with the \texttt{svy} prefix. By default, \texttt{vce(robust)} uses \( \hat{\sigma}_j^2 = \{ n/(n - k) \} u_j^2 \) as an estimate of the variance of the \( j \)th observation, where \( u_j \) is the calculated residual and \( n/(n - k) \) is included to improve the overall estimate's small-sample properties.

\texttt{vce(hc2)} instead uses \( u_j^2/(1 - h_{jj}) \) as the observation's variance estimate, where \( h_{jj} \) is the \( j \)th diagonal element of the hat (projection) matrix. This produces an unbiased estimate of the covariance matrix if the model is homoskedastic. \texttt{vce(hc2)} tends to produce slightly more conservative confidence intervals than \texttt{vce(robust)}.

\texttt{vce(hc3)} uses \( u_j^2/(1 - h_{jj})^2 \) as suggested by Davidson and MacKinnon (1993 and 2004), who report that this often produces better results when the model is heteroskedastic. \texttt{vce(hc3)} produces confidence intervals that tend to be even more conservative.

See, in particular, Davidson and MacKinnon (2004, 239), who advocate the use of \texttt{vce(hc2)} or \texttt{vce(hc3)} instead of the plain robust estimator for nonlinear least squares.

\[ \text{level(#); see [R] estimation options.} \]

\texttt{leave} leaves behind after estimation a set of new variables with the same names as the estimated parameters containing the derivatives of \( E(y) \) with respect to the parameters. If the dataset contains an existing variable with the same name as a parameter, then using \texttt{leave} causes \texttt{nl} to issue an error message with return code 110.

\texttt{leave} may not be specified with \texttt{vce(cluster clustvar)} or the \texttt{svy} prefix.

\texttt{title(string)} specifies an optional title that will be displayed just above the table of parameter estimates.

\texttt{title2(string)} specifies an optional subtitle that will be displayed between the title specified in \texttt{title(\textbf{\texttt{}}} and the table of parameter estimates. If \texttt{title2(\textbf{\texttt{}}} is specified but \texttt{title(\textbf{\texttt{}}} is not, \texttt{title2(\textbf{\texttt{}}} has the same effect as \texttt{title(\textbf{\texttt{}})}.

\[ \text{display_options: cformat(\%fmt), pformat(\%fmt), sformat(\%fmt), and nolstretch; see [R] estimation options.} \]

\[ \text{Optimization} \]

\[ \text{optimization_options: iterate(#), [no]log, trace. iterate() specifies the maximum number of iterations, log/nolog specifies whether to show the iteration log, and trace specifies that the iteration log should include the current parameter vector. These options are seldom used.} \]

\[ \text{eps(#)} \text{ specifies the convergence criterion for successive parameter estimates and for the residual sum of squares. The default is \texttt{eps(1e-5)}.} \]

\[ \text{delta(#)} \text{ specifies the relative change in a parameter to be used in computing the numeric derivatives. The derivative for parameter \( \beta_i \) is computed as } \{ f(X, \beta_1, \beta_2, \ldots, \beta_i + d, \beta_{i+1}, \ldots) - f(X, \beta_1, \beta_2, \ldots, \beta_i, \beta_{i+1}, \ldots) \} / d, \text{ where } d \text{ is } \delta(\beta_i + \delta). \text{ The default is \texttt{delta(4e-7)}.} \]

The following options are available with \texttt{nl} but are not shown in the dialog box:

\[ \text{coefficient; see [R] estimation options.} \]
Remarks and examples

Remarks are presented under the following headings:

- Substitutable expressions
- Substitutable expression programs
- Built-in functions
- Lognormal errors
- Other uses
- Weights
- Potential errors
- General comments on fitting nonlinear models
- Function evaluator programs

`nl` fits an arbitrary nonlinear function by least squares. The interactive version allows you to enter the function directly on the command line or dialog box using substitutable expressions. You can write a substitutable expression program for functions that you fit frequently to save yourself time. Finally, function evaluator programs give you the most flexibility in defining your nonlinear function, though they are more complicated to use.

The next section explains the substitutable expressions that are used to define the regression function, and the section thereafter explains how to write substitutable expression program files so that you do not need to type in commonly used functions over and over. Later sections highlight other features of `nl`.

The final section discusses function evaluator programs. If you find substitutable expressions adequate to define your nonlinear function, then you can skip that section entirely. Function evaluator programs are generally needed only for complicated problems, such as multistep estimators. The program receives a vector of parameters at which it is to compute the function and a variable into which the results are to be placed.

Substitutable expressions

You define the nonlinear function to be fit by `nl` by using a substitutable expression. Substitutable expressions are just like any other mathematical expressions involving scalars and variables, such as those you would use with Stata’s `generate` command, except that the parameters to be estimated are bound in braces. See [U] 13.2 Operators and [U] 13.3 Functions for more information on expressions.

For example, suppose that you wish to fit the function

\[ y_i = \beta_0(1 - e^{-\beta_1 x_i}) + \epsilon_i \]

where \( \beta_0 \) and \( \beta_1 \) are the parameters to be estimated and \( \epsilon_i \) is an error term. You would simply type

```
.nl (y = {b0}* (1 - exp(-1*{b1}*x)))
```

You must enclose the entire equation in parentheses. Because \( b0 \) and \( b1 \) are enclosed in braces, `nl` knows that they are parameters in the model. `nl` will initialize \( b0 \) and \( b1 \) to zero by default. To request that `nl` initialize \( b0 \) to 1 and \( b1 \) to 0.25, you would type

```
.nl (y = {b0=1}* (1 - exp(-1*{b1=0.25}*x)))
```

That is, inside the braces denoting a parameter, you put the parameter name followed by an equal sign and the initial value. If a parameter appears in your function multiple times, you need only specify an initial value only once (or never, if you wish to set the initial value to zero). If you do specify more than one initial value for the same parameter, `nl` will use the last value given. Parameter names must follow the same conventions as variable names. See [U] 11.3 Naming conventions.
Frequently, even nonlinear functions contain linear combinations of variables. As an example, suppose that you wish to fit the function

\[
y_i = \beta_0 \left\{ 1 - e^{-(\beta_1 x_{1i} + \beta_2 x_{2i} + \beta_3 x_{3i})} \right\} + \epsilon_i
\]

`nl` allows you to declare a linear combination of variables by using the shorthand notation

```
.nl (y = {b0=1}*(1 - exp(-1*{xb: x1 x2 x3})))
```

In the syntax `{xb: x1 x2 x3}`, you are telling `nl` that you are declaring a linear combination named `xb` that is a function of three variables, `x1`, `x2`, and `x3`. `nl` will create three parameters, named `xb_x1`, `xb_x2`, and `xb_x3`, and initialize them to zero. Instead of typing the previous command, you could have typed

```
.nl (y = {b0=1}*(1 - exp(-1*({xb_x1}*x1 + {xb_x2}*x2 + {xb_x3}*x3])))
```

and yielded the same result. You can refer to the parameters created by `nl` in the linear combination later in the function, though you must declare the linear combination first if you intend to do that. When creating linear combinations, `nl` ensures that the parameter names it chooses are unique and have not yet been used in the function.

In general, there are three rules to follow when defining substitutable expressions:

1. Parameters of the model are bound in braces: `{b0}`, `{param}`, etc.
2. Initial values for parameters are given by including an equal sign and the initial value inside the braces: `{b0=1}`, `{param=3.571}`, etc.
3. Linear combinations of variables can be included using the notation `{eqname:varlist}`, for example, `{xb: mpg price weight}`, `{score: w x z}`, etc. Parameters of linear combinations are initialized to zero.

If you specify initial values by using the `initial()` option, they override whatever initial values are given within the substitutable expression. Substitutable expressions are so named because, once values are assigned to the parameters, the resulting expression can be handled by `generate` and `replace`.

### Example 1

We wish to fit the CES production function

\[
\ln Q_i = \beta_0 - \frac{1}{\rho} \ln \left\{ \delta K_i^{-\rho} + (1 - \delta) L_i^{-\rho} \right\} + \epsilon_i
\]

where \( \ln Q_i \) is the log of output for firm \( i \); \( K_i \) and \( L_i \) are firm \( i \)'s capital and labor usage, respectively; and \( \epsilon_i \) is a regression error term. Because \( \rho \) appears in the denominator of a fraction, zero is not a feasible initial value; for a CES production function, \( \rho = 1 \) is a reasonable choice. Setting \( \delta = 0.5 \) implies that labor and capital have equal impacts on output, which is also a reasonable choice for an initial value. We type
. use http://www.stata-press.com/data/r14/production
. nl (lnoutput = {b0} - 1/{rho=1}*ln({delta=0.5}*capital`(-1*{rho}) +
> (1 - {delta})*labor`(-1*{rho})))
(obs = 100)
Iteration 0: residual SS = 29.38631
Iteration 1: residual SS = 29.36637
Iteration 2: residual SS = 29.36583
Iteration 3: residual SS = 29.36581
Iteration 4: residual SS = 29.36581
Iteration 5: residual SS = 29.36581
Iteration 6: residual SS = 29.36581
Iteration 7: residual SS = 29.36581

Source | SS df MS
------|--------------
Model  | 91.144992 2 45.5724962
Residual | 29.365806 97 .302740263
Total  | 120.5108 99 1.21728079

lnoutput
| Coef. Std. Err. t P>|t| [95% Conf. Interval]
--------|--------------|--------|--------|-----------------|-----------------|
/b0     | 3.792158  .099682 38.04 0.000 3.594316 3.989999
/rho   | 1.386993  .472584 2.93 0.004  .4490443 2.324941
/delta | .4823616  .0519791 9.28 0.000  .3791975 .5855258

Parameter b0 taken as constant term in model & ANOVA table

nl will attempt to find a constant term in the model and, if one is found, mention it at the bottom of
the output. nl found b0 to be a constant because the partial derivative \( \frac{\partial \ln Q_i}{\partial b_0} \) has a coefficient
of variation less than \( \text{eps() in the estimation sample.} \)

The elasticity of substitution for the CES production function is \( \sigma = 1/(1 + \rho) \); and, having fit
the model, we can use nlcom to estimate it:

. nlcom (1/(1 + _b[/rho]))
   _nl_1: 1/(1 + _b[/rho])

| lnoutput | Coef. Std. Err. z P>|z| [95% Conf. Interval]
----------|--------------|--------|--------|-----------------|-----------------|
   _nl_1   | .4189372  .0829424 5.05 0.000  .256373  .5815014

See [R] nlcom and [U] 13.5 Accessing coefficients and standard errors for more information.

nl's output closely mimics that of regress; see [R] regress for more information. The \( R^2 \), sums
of squares, and similar statistics are calculated in the same way that regress calculates them. If
no "constant" term is specified, the usual caveats apply to the interpretation of the \( R^2 \) statistic; see
the comments and references in Goldstein (1992). Unlike regress, nl does not report a model \( F \)
statistic, because a test of the joint significance of all the parameters except the constant term may
not be relevant in a nonlinear model.
Substitutable expression programs

If you fit the same model often or if you want to write an estimator that will operate on whatever variables you specify, then you will want to write a substitutable expression program. That program will return a macro containing a substitutable expression that \texttt{nl} can then evaluate, and it may optionally calculate initial values as well. The name of the program must begin with the letters \texttt{nl}.

To illustrate, suppose that you use the CES production function often in your work. Instead of typing in the formula each time, you can write a program like this:

```stata
program nlces, rclass
version 14.2
syntax varlist(min=3 max=3) [if]
local logout : word 1 of `varlist'
local capital : word 2 of `varlist'
local labor : word 3 of `varlist'
// Initial value for b0 given delta=0.5 and rho=1
tempvar y
generate double `y' = `logout' + ln(0.5*`capital'^-1 + 0.5*`labor'^-1)
summarize `y' if', meanonly
local b0val = r(mean)
// Terms for substitutable expression
local capterm "\{(delta=0.5)*\`capital'^(-1*\{rho\})\}"
local labterm "\{(1-{delta})*\`labor'^(-1*\{rho\})\}"
local term2 "1/{rho=1}*ln(`capterm' + `labterm')"
// Return substitutable expression and title
return local eq "`logout' = {b0=`b0val} - `term2'"
return local title "CES ftn., ln Q=`logout', K=`capital', L=`labor'"
end
```

The program accepts three variables for log output, capital, and labor, and it accepts an \texttt{if} \texttt{exp} qualifier to restrict the estimation sample. All programs that you write to use with \texttt{nl} must accept an \texttt{if} \texttt{exp} qualifier because, when \texttt{nl} calls the program, it passes a binary variable that marks the estimation sample (the variable equals one if the observation is in the sample and zero otherwise). When calculating initial values, you will want to restrict your computations to the estimation sample, and you can do so by using \texttt{if} with any commands that accept \texttt{if} \texttt{exp} qualifiers. Even if your program does not calculate initial values or otherwise use the \texttt{if} qualifier, the \texttt{syntax} statement must still allow it. See [P] syntax for more information on the \texttt{syntax} command and the use of \texttt{if}.

As in the previous example, reasonable initial values for $\delta$ and $\rho$ are 0.5 and 1, respectively. Conditional on those values, (1) can be rewritten as

$$\beta_0 = \ln Q_i + \ln(0.5 K_i^{-1} + 0.5 L_i^{-1}) - \epsilon_i$$

so a good initial value for $\beta_0$ is the mean of the right-hand side of (2) ignoring $\epsilon_i$. Lines 7–10 of the function evaluator program calculate that mean and store it in a local macro. Notice the use of \texttt{if} in the \texttt{summarize} statement so that the mean is calculated only for the estimation sample.

The final part of the program returns two macros. The macro \texttt{title} is optional and defines a short description of the model that will be displayed in the output immediately above the table of parameter estimates. The macro \texttt{eq} is required and defines the substitutable expression that \texttt{nl} will use. If the expression is short, you can define it all at once. However, because the expression used here is somewhat lengthy, defining local macros and then building up the final expression from them is easier.
To verify that there are no errors in your program, you can call it directly and then use `return` list:

```
. use http://www.stata-press.com/data/r14/production
. nlces lnoutput capital labor
(output omitted)
. return list
macros:
  r(title) : "CES ftn., ln Q=lnoutput, K=capital, L=labor"
  r(eq) : "lnoutput = {b0=3.711606264663641} - 1/{rho=1}*ln({delta}> a=0.5)*capital^(-1*{rho}) + (1-{delta})*labor^(-1*{rho}))"
```

The macro `r(eq)` contains the same substitutable expression that we specified at the command line in the preceding example, except for the initial value for `b0`. In short, an `nl` substitutable expression program should return in `r(eq)` the same substitutable expression you would type at the command line. The only difference is that when writing a substitutable expression program, you do not bind the entire expression inside parentheses.

Having written the program, you can use it by typing

```
. nl ces: lnoutput capital labor
```

(There is a space between `nl` and `ces`.) The output is identical to that shown in example 1, save for the title defined in the function evaluator program that appears immediately above the table of parameter estimates.

---

**Technical note**

You will want to store `nlces` as an ado-file called `nlces.ado`. The alternative is to type the code into Stata interactively or to place the code in a do-file. While those alternatives are adequate for occasional use, if you save the program as an ado-file, you can use the function anytime you use Stata without having to redefine the program. When `nl` attempts to execute `nlces`, if the program is not in Stata’s memory, Stata will search the disk(s) for an ado-file of the same name and, if found, automatically load it. All you have to do is name the file with the `.ado` suffix and then place it in a directory where Stata will find it. You should put the file in the directory Stata reserves for user-written ado-files, which, depending on your operating system, is `c:\ado\personal` (Windows), `~/ado/personal` (Unix), or `~/ado:personal` (Mac). See [U] 17 Ado-files.

Sometimes you may want to pass additional options to the substitutable expression program. You can modify the `syntax` statement of your program to accept whatever options you wish. Then when you call `nl` with the syntax

```
. nl func_prog: varlist, options
```

any `options` that are not recognized by `nl` (see the table of options at the beginning of this entry) are passed on to your function evaluator program. The only other restriction is that your program cannot accept an option named `at` because `nl` uses that option with function evaluator programs.

---

**Built-in functions**

Some functions are used so often that `nl` has them built in so that you do not need to write them yourself. `nl` automatically chooses initial values for the parameters, though you can use the `initial(...)` option to override them.
Three alternatives are provided for exponential regression with one asymptote:

\begin{align*}
\text{exp3} & \quad y_i = \beta_0 + \beta_1 \beta_2 x_i + \epsilon_i \\
\text{exp2} & \quad y_i = \beta_1 \beta_2 x_i + \epsilon_i \\
\text{exp2a} & \quad y_i = \beta_1 (1 - \beta_2 x_i) + \epsilon_i
\end{align*}

For instance, typing \texttt{nl exp3: ras dvl} fits the three-parameter exponential model (parameters \( \beta_0, \beta_1, \text{ and } \beta_2 \)) using \( y_i = \text{ras} \) and \( x_i = \text{dvl} \).

Two alternatives are provided for the logistic function (symmetric sigmoid shape; not to be confused with logistic regression):

\begin{align*}
\text{log4} & \quad y_i = \beta_0 + \beta_1 \left[ 1 + \exp\{-\beta_2 (x_i - \beta_3)\} \right] + \epsilon_i \\
\text{log3} & \quad y_i = \beta_1 \left[ 1 + \exp\{-\beta_2 (x_i - \beta_3)\} \right] + \epsilon_i
\end{align*}

Finally, two alternatives are provided for the Gompertz function (asymmetric sigmoid shape):

\begin{align*}
\text{gom4} & \quad y_i = \beta_0 + \beta_1 \exp\{-\exp\{-\beta_2 (x_i - \beta_3)\} \} + \epsilon_i \\
\text{gom3} & \quad y_i = \beta_1 \exp\{-\exp\{-\beta_2 (x_i - \beta_3)\} \} + \epsilon_i
\end{align*}

Lognormal errors

A nonlinear model with errors that are independent and identically distributed normal may be written as

\[ y_i = f(x_i, \beta) + u_i, \quad u_i \sim N(0, \sigma^2) \]  \hspace{1cm} (3)

for \( i = 1, \ldots, n \). If the \( y_i \) are thought to have a \( k \)-shifted lognormal instead of a normal distribution—that is, \( \ln(y_i - k) \sim N(\zeta_i, \tau^2) \), and the systematic part \( f(x_i, \beta) \) of the original model is still thought appropriate for \( y_i \)—the model becomes

\[ \ln(y_i - k) = \zeta_i + v_i = \ln\{f(x_i, \beta) - k\} + v_i, \quad v_i \sim N(0, \tau^2) \]  \hspace{1cm} (4)

This model is fit if \texttt{nlslq}(k) is specified.

If model (4) is correct, the variance of \( y_i - k \) is proportional to \( \{f(x_i, \beta) - k\}^2 \). Probably the most common case is \( k = 0 \), sometimes called “proportional errors” because the standard error of \( y_i \) is proportional to its expectation, \( f(x_i, \beta) \). Assuming that the value of \( k \) is known, (4) is just another nonlinear model in \( \beta \), and it may be fit as usual. However, we may wish to compare the fit of (3) with that of (4) using the residual sum of squares (RSS) or the deviance \( D, D = -2 \times \log\text{-likelihood} \), from each model. To do so, we must allow for the change in scale introduced by the log transformation.

Assuming then, the \( y_i \) to be normally distributed, Atkinson (1985, 85–87, 184), by considering the Jacobian \( \prod |\partial \ln(y_i - k)/\partial y_i| \), showed that multiplying both sides of (4) by the geometric mean of \( y_i - k, \bar{y} \), gives residuals on the same scale as those of \( y_i \). The geometric mean is given by

\[ \bar{y} = e^{n^{-1} \sum \ln(y_i - k)} \]

which is a constant for a given dataset. The residual deviance for (3) and for (4) may be expressed as

\[ D(\hat{\beta}) = \left\{ 1 + \ln(2\pi\hat{\sigma}^2) \right\} n \]  \hspace{1cm} (5)
where \( \hat{\beta} \) is the maximum likelihood estimate (MLE) of \( \beta \) for each model and \( n\hat{\sigma}^2 \) is the RSS from (3), or that from (4) multiplied by \( \hat{y}^2 \).

Because (3) and (4) are models with different error structures but the same functional form, the arithmetic difference in their RSS or deviances is not easily tested for statistical significance. However, if the deviance difference is large (>4, say), we would naturally prefer the model with the smaller deviance. Of course, the residuals for each model should be examined for departures from assumptions (nonconstant variance, nonnormality, serial correlations, etc.) in the usual way.

Alternatively, consider modeling

\[
E(y_i) = 1/(C + Ae^{Bx_i}) \quad (6)
\]

\[
E(1/y_i) = E(y_i') = C + Ae^{Bx_i} \quad (7)
\]

where \( C, A, \) and \( B \) are parameters to be estimated. Using the data \( (y, x) = (0.04, 5), (0.06, 12), (0.08, 25), (0.1, 35), (0.15, 42), (0.2, 48), (0.25, 60), (0.3, 75), \) and \( (0.5, 120) \) (Danuso 1991), fitting the models yields

<table>
<thead>
<tr>
<th>Model</th>
<th>( C )</th>
<th>( A )</th>
<th>( B )</th>
<th>RSS</th>
<th>Deviance</th>
</tr>
</thead>
<tbody>
<tr>
<td>(6)</td>
<td>1.781</td>
<td>25.74</td>
<td>-0.03926</td>
<td>-0.001640</td>
<td>-51.95</td>
</tr>
<tr>
<td>(6) with lnlsq(0)</td>
<td>1.799</td>
<td>25.45</td>
<td>-0.04051</td>
<td>-0.001431</td>
<td>-53.18</td>
</tr>
<tr>
<td>(7)</td>
<td>1.781</td>
<td>25.74</td>
<td>-0.03926</td>
<td>8.197</td>
<td>24.70</td>
</tr>
<tr>
<td>(7) with lnlsq(0)</td>
<td>1.799</td>
<td>25.45</td>
<td>-0.04051</td>
<td>3.651</td>
<td>17.42</td>
</tr>
</tbody>
</table>

There is little to choose between the two versions of the logistic model (6), whereas for the exponential model (7), the fit using lnlsq(0) is much better (a deviance difference of 7.28). The reciprocal transformation has introduced heteroskedasticity into \( y_i' \), which is countered by the proportional errors property of the lognormal distribution implicit in lnlsq(0). The deviances are not comparable between the logistic and exponential models because the change of scale has not been allowed for, although in principle it could be.

**Other uses**

Even if you are fitting linear regression models, you may find that nl can save you some typing. Because you specify the parameters of your model explicitly, you can impose constraints on them directly.

> **Example 2**

In example 2 of [R] cnsreg, we showed how to fit the model

\[
mpg = \beta_0 + \beta_1 \text{price} + \beta_2 \text{weight} + \beta_3 \text{displ} + \beta_4 \text{gear\_ratio} + \beta_5 \text{foreign} + \beta_6 \text{length} + u
\]

subject to the constraints

\[
\beta_1 = \beta_2 = \beta_3 = \beta_6
\]

\[
\beta_4 = -\beta_5 = \beta_0/20
\]
An alternative way is to use `nl`:

```
. use http://www.stata-press.com/data/r14/auto, clear
(1978 Automobile Data)
. nl (mpg = {b0} + {b1}*price + {b1}*weight + {b1}*displ +
   > {b0}/20*gear_ratio - {b0}/20*foreign + {b1}*length)
   (obs = 74)
Iteration 0: residual SS = 1578.522
Iteration 1: residual SS = 1578.522
Source | SS      df MS
-------+---------+--------+---------+-----------+--------+----------+----------+
Model   | 34429.478 2 17214.7389 R-squared = 0.9562
Residual| 1578.5223 72 21.9239203 Adj R-squared = 0.9549
Total   | 36008    74 486.594595 Res. dev. = 436.4562
-------+---------+--------+---------+-----------+--------+----------+----------+
mpg     | Coef.   Std. Err. t P>|t|    [95% Conf. Interval]
-------+---------+--------+---------+-----------+--------+----------+----------+
/b0     | 26.52229 1.375178 19.29 0.000 23.78092 29.26365
/b1     | -.000923 .0001534 -6.02 0.000 -.0012288 -.0006172
-------+---------+--------+---------+-----------+--------+----------+----------+
```

The point estimates and standard errors for \( \beta_0 \) and \( \beta_1 \) are identical to those reported in example 2 of \[R\] `cnsreg`. To get the estimate for \( \beta_4 \), we can use `nlcom`:

```
. nlcom _b[/b0]/20
    _nl_1: _b[/b0]/20
```

```
mpg     | Coef.   Std. Err. z P>|z|    [95% Conf. Interval]
-------+---------+--------+---------+-----------+--------+----------+----------+
_nl_1   | 1.326114 .0687589 19.29 0.000 1.191349 1.460879
-------+---------+--------+---------+-----------+--------+----------+----------+
```

The advantage to using `nl` is that we do not need to use the `constraint` command six times.

`nl` is also a useful tool when doing exploratory data analysis. For example, you may want to run a regression of \( y \) on a function of \( x \), though you have not decided whether to use \( \sqrt{x} \) or \( \ln(x) \). You can use `nl` to run both regressions without having first to generate two new variables:

```
. nl (y = {b0} + {b1}*ln(x))
. nl (y = {b0} + {b1}*sqrt(x))
```

Poi (2008) shows the advantages of using `nl` when marginal effects of transformed variables are desired as well.

**Weights**

Weights are specified in the usual way—analytic and frequency weights as well as `iweights` are supported; see \[U\] 20.23 Weighted estimation. Use of analytic weights implies that the \( y_i \) have different variances. Therefore, model (3) may be rewritten as

\[
y_i = f(x_i, \beta) + u_i, \quad u_i \sim N(0, \sigma^2/w_i)
\]

(3a)

where \( w_i \) are (positive) weights, assumed to be known and normalized such that their sum equals the number of observations. The residual deviance for (3a) is

\[
D(\hat{\beta}) = \{1 + \ln(2\pi\hat{\sigma}^2)\}n - \sum \ln(w_i)
\]

(5a)
[compare with (5)], where
\[ n\hat{\sigma}^2 = \text{RSS} = \sum w_i \{ y_i - f(x_i, \hat{\beta}) \}^2 \]

Defining and fitting a model equivalent to (4) when weights have been specified as in (3a) is not straightforward and has not been attempted. Thus deviances using and not using the \texttt{lnlsq()} option may not be strictly comparable when analytic weights (other than 0 and 1) are used.

You do not need to modify your substitutable expression in any way to use weights. If, however, you write a substitutable expression program, then you should account for weights when obtaining initial values. When \texttt{nl} calls your program, it passes whatever weight expression (if any) was specified by the user. Here is an outline of a substitutable expression program that accepts weights:

```
program nl name, rclass
    version 14.2
    syntax varlist [aw fw iw] if ...
    // Obtain initial values allowing weights
    // Use the syntax ['weight''exp']. For example,
    summarize varname ['weight''exp'] 'if'
    regress depvar varlist ['weight''exp'] 'if'
    ...
    // Return substitutable expression
    return local eq "substitutable expression"
    return local title "description of estimator"
end
```

For details on how the \texttt{syntax} command processes weight expressions, see \texttt{[P] syntax}.

**Potential errors**

\texttt{nl} is reasonably robust to the inability of your nonlinear function to be evaluated at some parameter values. \texttt{nl} does assume that your function can be evaluated at the initial values of the parameters. If your function cannot be evaluated at the initial values, an error message is issued with return code 480. Recall that if you do not specify an initial value for a parameter, then \texttt{nl} initializes it to zero. Many nonlinear functions cannot be evaluated when some parameters are zero, so in those cases specifying alternative initial values is crucial.

Thereafter, as \texttt{nl} changes the parameter values, it monitors your function for unexpected missing values. If these are detected, \texttt{nl} backs up. That is, \texttt{nl} finds a point between the previous, known-to-be-good parameter vector and the new, known-to-be-bad vector at which the function can be evaluated and continues its iterations from that point.

\texttt{nl} requires that once a parameter vector is found where the predictions can be calculated, small changes to the parameter vector be made to calculate numeric derivatives. If a boundary is encountered at this point, an error message is issued with return code 481.

When specifying \texttt{lnlsq()}, an attempt to take logarithms of \( y_i - k \) when \( y_i \leq k \) results in an error message with return code 482.

If \texttt{iterate()} iterations are performed and estimates still have not converged, results are presented with a warning, and the return code is set to 430.

If you use the programmed substitutable expression version of \texttt{nl} with a function evaluator program, or vice versa, Stata issues an error message. Verify that you are using the syntax appropriate for the program you have.
General comments on fitting nonlinear models

Achieving convergence is often problematic. For example, a unique minimum of the sum-of-squares function may not exist. Much literature exists on different algorithms that have been used, on strategies for obtaining good initial parameter values, and on tricks for parameterizing the model to make its behavior as linear-like as possible. Selected references are Kennedy and Gentle (1980, chap. 10) for computational matters and Ross (1990) and Ratkowsky (1983) for all three aspects. Ratkowsky’s book is particularly clear and approachable, with useful discussion on the meaning and practical implications of intrinsic and parameter-effects nonlinearity. An excellent text on nonlinear estimation is Gallant (1987). Also see Davidson and MacKinnon (1993 and 2004).

To enhance the success of \texttt{nl}, pay attention to the form of the model fit, along the lines of Ratkowsky and Ross. For example, Ratkowsky (1983, 49–59) analyzes three possible three-parameter yield-density models for plant growth:

\[
E(y_i) = \begin{cases} 
(\alpha + \beta x_i)^{-1/\theta} \\
(\alpha + \beta x_i + \gamma x_i^2)^{-1} \\
(\alpha + \beta x_i^\phi)^{-1}
\end{cases}
\]

All three models give similar fits. However, he shows that the second formulation is dramatically more linear-like than the other two and therefore has better convergence properties. In addition, the parameter estimates are virtually unbiased and normally distributed, and the asymptotic approximation to the standard errors, correlations, and confidence intervals is much more accurate than for the other models. Even within a given model, the way the parameters are expressed (for example, \(\phi x_i\) or \(e^{\theta x_i}\)) affects the degree of linearity and convergence behavior.

Function evaluator programs

Occasionally, a nonlinear function may be so complex that writing a substitutable expression for it is impractical. For example, there could be many parameters in the model. Alternatively, if you are implementing a two-step estimator, writing a substitutable expression may be altogether impossible. Function evaluator programs can be used in these situations.

\texttt{nl} will pass to your function evaluator program a list of variables, a weight expression, a variable marking the estimation sample, and a vector of parameters. Your program is to replace the dependent variable, which is the first variable in the variables list, with the values of the nonlinear function evaluated at those parameters. As with substitutable expression programs, the first two letters of the name must be \texttt{nl}.

To focus on the mechanics of the function evaluator program, again let’s compare the CES production function to the previous examples. The function evaluator program is
Unlike the previous \texttt{nlces} program, this one is not declared to be r-class. The \texttt{syntax} statement again accepts three variables: one for log output, one for capital, and one for labor. An \texttt{if} exp is again required because \texttt{nl} will pass a binary variable marking the estimation sample. All function evaluator programs must accept an option named \texttt{at()} that takes a \texttt{name} as an argument—that is how \texttt{nl} passes the parameter vector to your program.

The next part of the program retrieves the output, labor, and capital variables from the variables list. It then breaks up the temporary matrix \texttt{at} and retrieves the parameters \texttt{b0}, \texttt{rho}, and \texttt{delta}. Pay careful attention to the order in which the parameters refer to the columns of the \texttt{at} matrix because that will affect the syntax you use with \texttt{nl}. The temporary names you use inside this program are immaterial, however.

The rest of the program computes the nonlinear function, using some temporary variables to hold intermediate results. The final line of the program then replaces the dependent variable with the values of the function. Notice the use of \texttt{if} to restrict attention to the estimation sample. \texttt{nl} makes a copy of your dependent variable so that when the command is finished your data are left unchanged.

To use the program and fit your model, you type

\begin{verbatim}
  . use http://www.stata-press.com/data/r14/production, clear
  . nl ces2 @ lnoutput capital labor, parameters(b0 rho delta)
       > initial(b0 0 rho 1 delta 0.5)
\end{verbatim}

The output is again identical to that shown in \texttt{example 1}. The order in which the parameters were specified in the \texttt{parameters()} option is the same in which they are retrieved from the \texttt{at} matrix in the program. To initialize them, you simply list the parameter name, a space, the initial value, and so on.

If you use the \texttt{nparameters()} option instead of the \texttt{parameters()} option, the parameters are named \texttt{b1}, \texttt{b2}, ..., \texttt{bk}, where \texttt{k} is the number of parameters. Thus you could have typed

\begin{verbatim}
  . nl ces2 @ lnoutput capital labor, nparameters(3) initial(b1 0 b2 1 b3 0.5)
\end{verbatim}

With that syntax, the parameters called \texttt{b0}, \texttt{rho}, and \texttt{delta} in the program will be labeled \texttt{b1}, \texttt{b2}, and \texttt{b3}, respectively. In programming situations or if there are many parameters, instead of listing the parameter names and initial values in the \texttt{initial()} option, you may find it more convenient to pass a column vector. In those cases, you could type

\begin{verbatim}
  . matrix myvals = (0, 1, 0.5)
  . nl ces2 @ lnoutput capital labor, nparameters(3) initial(myvals)
\end{verbatim}
In summary, a function evaluator program receives a list of variables, the first of which is the dependent variable that you are to replace with the values of your nonlinear function. Additionally, it must accept an `if exp`, as well as an option named `at` that will contain the vector of parameters at which `nl` wants the function evaluated. You are then free to do whatever is necessary to evaluate your function and replace the dependent variable.

If you wish to use weights, your function evaluator program’s `syntax` statement must accept them. If your program consists only of, for example, `generate` statements, you need not do anything with the weights passed to your program. However, if in calculating the nonlinear function you use commands such as `summarize` or `regress`, then you will want to use the weights with those commands.

As with substitutable expression programs, `nl` will pass to it any options specified that `nl` does not accept, providing you with a way to pass more information to your function.

**Technical note**

Before version 9 of Stata, the `nl` command used a different syntax, which required you to write an `nlfcn` program, and it did not have a syntax for interactive use other than the seven functions that were built-in. The old syntax of `nl` still works, and you can still use those `nlfcn` programs. If `nl` does not see a colon, an at sign, or a set of parentheses surrounding the equation in your command, it assumes that the old syntax is being used.

The current version of `nl` uses scalars and matrices to store intermediate calculations instead of local and global macros as the old version did, so the current version produces more accurate results. In practice, however, any discrepancies are likely to be small.
Stored results

`nl` stores the following in `e()`: 

Scalars

- `e(N)` number of observations
- `e(k)` number of parameters
- `e(k_eq_model)` number of equations in overall model test; always 0
- `e(df_m)` model degrees of freedom
- `e(df_r)` residual degrees of freedom
- `e(df_t)` total degrees of freedom
- `e(mss)` model sum of squares
- `e(rss)` residual sum of squares
- `e(tss)` total sum of squares
- `e(mms)` model mean square
- `e(msr)` residual mean square
- `e(ll)` log likelihood assuming i.i.d. normal errors
- `e(r2)` \( R^2 \)-squared
- `e(r2_a)` adjusted \( R^2 \)-squared
- `e(rmse)` root mean squared error
- `e(dev)` residual deviance
- `e(N_clust)` number of clusters
- `e(lnlsq)` value of `lnlsq` if specified
- `e(log_t)` 1 if `lnlsq` specified, 0 otherwise
- `e(gm_2)` square of geometric mean of \((y-k)\) if `lnlsq`; 1 otherwise
- `e(cj)` position of constant in `e(b)` or 0 if no constant
- `e(delta)` relative change used to compute derivatives
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(converge)` 1 if converged, 0 otherwise

Macros

- `e(cmd)` `nl`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(title_2)` secondary title in estimation output
- `e(clustvar)` name of cluster variable
- `e(hac_kernel)` HAC kernel
- `e(hac_lag)` HAC lag
- `e(vce)` `vcetype` specified in `vce()`
- `e(vcetype)` title used to label Std. Err.
- `e(type)` 1 = interactively entered expression
- 2 = substitutable expression program
- 3 = function evaluator program
- `e(sexp)` substitutable expression
- `e(params)` names of parameters
- `e(funcprog)` function evaluator program
- `e(rhs)` contents of `variables()`
- `e(properties)` `b` `V`
- `e(predict)` program used to implement `predict`
- `e(marginsok)` predictions allowed by `margins`
- `e(marginsnotok)` predictions disallowed by `margins`

Matrices

- `e(b)` coefficient vector
- `e(init)` initial values vector
- `e(V)` variance–covariance matrix of the estimators

Functions

- `e(sample)` marks estimation sample
Methods and formulas

The derivation here is based on Davidson and MacKinnon (2004, chap. 6). Let \( \beta \) denote the \( k \times 1 \) vector of parameters, and write the regression function using matrix notation as \( y = f(x, \beta) + u \) so that the objective function can be written as

\[
SSR(\beta) = \{y - f(x, \beta)\}'D\{y - f(x, \beta)\}
\]

The \( D \) matrix contains the weights and is defined in \([\text{R}]\) \texttt{regress}; if no weights are specified, then \( D \) is the \( N \times N \) identity matrix. Taking a second-order Taylor series expansion centered at \( \beta_0 \) yields

\[
SSR(\beta) \approx SSR(\beta_0) + g'(\beta_0)(\beta - \beta_0) + \frac{1}{2}(\beta - \beta_0)'H(\beta_0)(\beta - \beta_0)
\] (8)

where \( g(\beta_0) \) denotes the \( k \times 1 \) gradient of \( SSR(\beta) \) evaluated at \( \beta_0 \) and \( H(\beta_0) \) denotes the \( k \times k \) Hessian of \( SSR(\beta) \) evaluated at \( \beta_0 \). Letting \( X \) denote the \( N \times k \) matrix of derivatives of \( f(x, \beta) \) with respect to \( \beta \), the gradient \( g(\beta) \) is

\[
g(\beta) = -2X'Du
\] (9)

\( X \) and \( u \) are obviously functions of \( \beta \), though for notational simplicity that dependence is not shown explicitly. The \((m,n)\) element of the Hessian can be written as

\[
H_{mn}(\beta) = -2 \sum_{i=1}^{N} d_{ii} \left[ \frac{\partial^2 f_i}{\partial \beta_m \partial \beta_n} u_i - X_{im} X_{in} \right]
\] (10)

where \( d_{ii} \) is the \( i \)th diagonal element of \( D \). As discussed in Davidson and MacKinnon (2004, chap. 6), the first term inside the brackets of (10) has expectation zero, so the Hessian can be approximated as

\[
H(\beta) = 2X'DX
\] (11)

Differentiating the Taylor series expansion of \( SSR(\beta) \) shown in (8) yields the first-order condition for a minimum

\[
g(\beta_0) + H(\beta_0)(\beta - \beta_0) = 0
\]

which suggests the iterative procedure

\[
\beta_{j+1} = \beta_j - \alpha H^{-1}(\beta_j)g(\beta_j)
\] (12)

where \( \alpha \) is a “step size” parameter chosen at each iteration to improve convergence. Using (9) and (11), we can write (12) as

\[
\beta_{j+1} = \beta_j + \alpha(X'DX)^{-1}X'Du
\] (13)

where \( X \) and \( u \) are evaluated at \( \beta_j \). Apart from the scalar \( \alpha \), the second term on the right-hand side of (13) can be computed via a (weighted) regression of the columns of \( X \) on the errors. \texttt{nl} computes the derivatives numerically and then calls \texttt{regress}. At each iteration, \( \alpha \) is set to one, and a candidate value \( \beta^*_{j+1} \) is computed by (13). If \( SSR(\beta^*_{j+1}) < SSR(\beta_j) \), then \( \beta_{j+1} = \beta^*_{j+1} \) and the iteration is complete. Otherwise, \( \alpha \) is halved, a new \( \beta^*_{j+1} \) is calculated, and the process is repeated. Convergence is declared when \( \alpha |\beta_{j+1,m} - \beta_j|m| + \tau \) for all \( m = 1, \ldots, k \). \texttt{nl} uses \( \tau = 10^{-3} \) and, by default, \( \epsilon = 10^{-5} \), though you can specify an alternative value of \( \epsilon \) with the \texttt{eps()} option.
As derived, for example, in Davidson and MacKinnon (2004, chap. 6), an expedient way to obtain the covariance matrix is to compute $u$ and the columns of $X$ at the final estimate $\hat{\beta}$ and then regress that $u$ on $X$. The covariance matrix of the estimated parameters of that regression serves as an estimate of $\text{Var}(\hat{\beta})$. If that regression employs a robust covariance matrix estimator, then the covariance matrix for the parameters of the nonlinear regression will also be robust.

All other statistics are calculated analogously to those in linear regression, except that the nonlinear function $f(x_i, \beta)$ plays the role of the linear function $x_i'\beta$. See [R] regress.

This command supports estimation with survey data. For details on VCEs with survey data, see [SVY] variance estimation.

Acknowledgments

The original version of nl was written by Patrick Royston (1992) of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model. Francesco Danuso’s menu-driven nonlinear regression program (1991) provided the inspiration.

</table>

* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.
† You must specify the `variables()` option with `nl`.
predict

Description for predict

predict creates a new variable containing predictions such as fitted values, residuals, probabilities, and expected values.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , statistic ]
predict [type] { stub* | newvar1 ... newvark } [if] [in] , scores
```

where \( k \) is the number of parameters in the model.

<td>ystar(a,b)</td>
<td>( E(y_j^<em>) ), ( y_j^</em> = \max{a, \min(y_j, b)} )</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Options for predict

- `yhat`, the default, calculates the fitted values.
- `residuals` calculates the residuals.
- `pr(a,b)` calculates \( \Pr(a < x_jb + u_j < b) \), the probability that \( y_j|x_j \) would be observed in the interval \( (a,b) \).
  - \( a \) and \( b \) may be specified as numbers or variable names; \( lb \) and \( ub \) are variable names;
  - `pr(20,30)` calculates \( \Pr(20 < x_jb + u_j < 30) \);
  - `pr(lb,ub)` calculates \( \Pr(lb < x_jb + u_j < ub) \); and
  - `pr(20,ub)` calculates \( \Pr(20 < x_jb + u_j < ub) \).
  - \( a \) missing \( (a \geq .) \) means \(-\infty\); `pr(.,30)` calculates \( \Pr(-\infty < x_jb + u_j < 30) \);
  - `pr(lb,30)` calculates \( \Pr(-\infty < x_jb + u_j < 30) \) in observations for which \( lb \geq . \)
  - and calculates \( \Pr(lb < x_jb + u_j < 30) \) elsewhere.
\( b \) missing \( (b \geq .) \) means \( +\infty \); \( \Pr(20, .) \) calculates \( \Pr(+\infty > x_j b + u_j > 20) \); 
\( \Pr(20, ub) \) calculates \( \Pr(+\infty > x_j b + u_j > 20) \) in observations for which \( ub \geq . \) and calculates \( \Pr(20 < x_j b + u_j < ub) \) elsewhere.

\( e(a,b) \) calculates \( E(x_j b + u_j \mid a < x_j b + u_j < b) \), the expected value of \( y_j \mid x_j \) conditional on \( y_j \mid x_j \) being in the interval \((a,b)\), meaning that \( y_j \mid x_j \) is truncated. \( a \) and \( b \) are specified as they are for \( \Pr() \).

\( ystar(a,b) \) calculates \( E(y_j^\ast) \), where \( y_j^\ast = a \) if \( x_j b + u_j \leq a \), \( y_j^\ast = b \) if \( x_j b + u_j \geq b \), and \( y_j^\ast = x_j b + u_j \) otherwise, meaning that \( y_j^\ast \) is censored. \( a \) and \( b \) are specified as they are for \( \Pr() \).

\( scores \) calculates the scores. The \( j \)th new variable created will contain the score for the \( j \)th parameter in \( e(b) \).

**margins**

**Description for margins**

\( \text{margins} \) estimates margins of response for fitted values.

**Menu for margins**

Statistics > Postestimation

**Syntax for margins**

\[
\text{margins} \quad \text{marginlist} \quad \text{options}
\]

\[
\text{margins} \quad \text{marginlist}, \quad \text{predict(statistic ...)} \quad \text{options}
\]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( _\text{hat} )</td>
<td>fitted values; the default</td>
</tr>
<tr>
<td>( \Pr(a,b) )</td>
<td>not allowed with \text{margins}</td>
</tr>
<tr>

<td>not allowed with \text{margins}</td>
</tr>
<tr>
<td>residuals</td>
<td>not allowed with \text{margins}</td>
</tr>
</tbody>
</table>

Statistics not allowed with \text{margins} are functions of stochastic quantities other than \( e(b) \).

For the full syntax, see \text{[R] margins}.  

Remarks and examples

Example 1

Obtaining predictions after fitting a nonlinear regression model with \texttt{nl} is no more difficult than obtaining predictions after fitting a linear regression model with \texttt{regress}. Here we fit a model of \texttt{mpg} on \texttt{weight}, allowing for a nonlinear relationship:

\begin{verbatim}
. use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
. nl (mpg = {b0} + {b1}*weight^{gamma=-.5}), variables(weight) nolog
(obs = 74)
\end{verbatim}

<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model</td>
<td>1646.4376</td>
<td>2</td>
<td>823.218806</td>
</tr>
<tr>
<td>Residual</td>
<td>797.02185</td>
<td>71</td>
<td>11.2256598</td>
</tr>
<tr>
<td>Total</td>
<td>2443.4595</td>
<td>73</td>
<td>33.4720474</td>
</tr>
</tbody>
</table>

Number of obs = 74
R-squared = 0.6738
Adj R-squared = 0.6646
Root MSE = 3.350472
Res. dev. = 385.8874

| mpg    | Coef.   | Std. Err. | t     | P>|t|  | [95% Conf. Interval] |
|--------|---------|-----------|-------|------|---------------------|
| /b0    | -18.17583 | 60.61762 | -0.30 | 0.765 | -139.0439, 102.6923 |
| /b1    | 1377.267  | 5292.379  | 0.26  | 0.795 | -9175.436, 11929.97 |
| /gamma | -0.4460916 | 0.6763641 | -0.66 | 0.512 | -1.794723, 0.9025401 |

Parameter b0 taken as constant term in model & ANOVA table

Now we obtain the predicted values of \texttt{mpg} and plot them in a graph along with the observed values:

\begin{verbatim}
. predict mpghat
(option yhat assumed; fitted values)
. scatter mpg weight || line mpghat weight, sort
\end{verbatim}
Suppose we wanted to know how sensitive mpg is to changes in weight for cars that weigh 3,000 pounds. We can use margins to find out:

```
. margins, eyex(weight) at(weight = 3000)
```

Warning: cannot perform check for estimable functions.

Conditional marginal effects

<table>
<thead>
<tr>
<th>Expression : Fitted values, predict()</th>
<th>Number of obs = 74</th>
</tr>
</thead>
<tbody>
<tr>
<td>ey/ex w.r.t. : weight</td>
<td></td>
</tr>
<tr>
<td>at : weight = 3000</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>Delta-method</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ey/ex</td>
</tr>
<tr>
<td>weight</td>
<td>-.8408119</td>
</tr>
<tr>
<td>Std. Err.</td>
<td>.0804339</td>
</tr>
<tr>
<td>z</td>
<td>-10.45</td>
</tr>
<tr>
<td>P&gt;</td>
<td>z</td>
</tr>
<tr>
<td>[95% Conf. Interval]</td>
<td>-.9984594 -.6831644</td>
</tr>
</tbody>
</table>

With the eyex() option, margins reports elasticities. These results show that if we increase weight by 1%, then mpg decreases by about 0.84%.

⚠️ Technical note

Observant readers will notice that margins issued a warning message stating that it could not perform its usual check for estimable functions. In the case of nl, as long as you do not specify the predict() option of margins or specify the default predict(yhat), you can safely ignore that message. The predicted values that nl produces are suitable for use with margins. However, if you specify any predict() options other than yhat, then the output from margins after using nl will not be correct.

⚠️ Also see

[R] nl — Nonlinear least-squares estimation
[U] 20 Estimation and postestimation commands
Description

\texttt{nlcom} computes point estimates, standard errors, test statistics, significance levels, and confidence intervals for (possibly) nonlinear combinations of parameter estimates after any Stata estimation command, including survey estimation. Results are displayed in the usual table format used for displaying estimation results. Calculations are based on the “delta method”, an approximation appropriate in large samples.

Quick start

Estimate the ratio of the coefficient of \texttt{x2} to the coefficient of \texttt{x1}
\begin{verbatim}
nlcom _b[x2]/_b[x1]
\end{verbatim}

Also estimate the ratio of the coefficient of \texttt{x3} to coefficient of \texttt{x1}
\begin{verbatim}
nlcom (_b[x2]/_b[x1]) (_b[x3]/_b[x1])
\end{verbatim}

Add labels to the ratios
\begin{verbatim}
nlcom (r21:_b[x2]/_b[x1]) (r31:_b[x3]/_b[x1])
\end{verbatim}

As above, but post estimates and use the \texttt{test} command to test that both ratios are equal to 1
\begin{verbatim}
nlcom (r21:_b[x2]/_b[x1]) (r31:_b[x3]/_b[x1]), post
test (r21 = 1) (r31 = 1)
\end{verbatim}

Estimate the ratio of the coefficients of factor indicators \texttt{2.a} and \texttt{3.a}
\begin{verbatim}
nlcom _b[2.a]/_b[3.a]
\end{verbatim}

Estimate the ratio of the coefficients of \texttt{x1} in the equations for \texttt{y1} and \texttt{y2} in a multiequation model
\begin{verbatim}
nlcom _b[y1:x1]/_b[y2:x1]
\end{verbatim}
Syntax

Nonlinear combination of estimators—one expression

```
nlcom [name:] exp [, options]
```

Nonlinear combinations of estimators—more than one expression

```
nlcom ([name:] exp) ([([name:] exp) ...]) [, options]
```

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

noheader and df(#) do not appear in the dialog box.

The second syntax means that if more than one expression is specified, each must be surrounded by parentheses. The optional name is any valid Stata name and labels the transformations.

`exp` is a possibly nonlinear expression containing

- `_b[coef]`
- `_b[eqno:coef]`
- `[eqno]coef`
- `[eqno]_b[coef]`

`eqno` is

- `##`
- `name`

`coef` identifies a coefficient in the model. `coef` is typically a variable name, a level indicator, an interaction indicator, or an interaction involving continuous variables. Level indicators identify one level of a factor variable and interaction indicators identify one combination of levels of an interaction; see [U] 11.4.3 Factor variables. `coef` may contain time-series operators; see [U] 11.4.4 Time-series varlists.

Distinguish between [ ], which are to be typed, and [ ], which indicate optional arguments.

Options

- level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by `set level`; see [U] 20.7 Specifying the width of confidence intervals.
- iterate(#) specifies the maximum number of iterations used to find the optimal step size in calculating numerical derivatives of the transformation(s) with respect to the original parameters. By default, the maximum number of iterations is 100, but convergence is usually achieved after only a few iterations. You should rarely have to use this option.
post causes \texttt{nlcom} to behave like a Stata estimation (\texttt{eclass}) command. When post is specified, \texttt{nlcom} will post the vector of transformed estimators and its estimated variance–covariance matrix to \texttt{e()}. This option, in essence, makes the transformation permanent. Thus you could, after posting, treat the transformed estimation results in the same way as you would treat results from other Stata estimation commands. For example, after posting, you could redisplay the results by typing \texttt{nlcom} without any arguments, or use \texttt{test} to perform simultaneous tests of hypotheses on linear combinations of the transformed estimators; see [R] \texttt{test}.

Specifying \texttt{post} clears out the previous estimation results, which can be recovered only by refitting the original model or by storing the estimation results before running \texttt{nlcom} and then restoring them; see [R] \texttt{estimates store}.

\textit{display_options:} \texttt{cformat(\%fmt)}, \texttt{pformat(\%fmt)}, \texttt{sformat(\%fmt)}, and \texttt{nolstretch}; see [R] \texttt{estimation options}.

The following options are available with \texttt{nlcom} but are not shown in the dialog box:

- \texttt{noheader} suppresses the output header.
- \texttt{df(#)} specifies that the $t$ distribution with # degrees of freedom be used for computing $p$-values and confidence intervals.

### Remarks and examples

Remarks are presented under the following headings:

- \textit{Introduction}
- \textit{Basics}
- \textit{Using the post option}
- \textit{Reparameterizing ML estimators for univariate data}
- \textit{nlcom versus eform}

### Introduction

\texttt{nlcom} and \texttt{predictnl} both use the delta method. They take nonlinear transformations of the estimated parameter vector from some fitted model and apply the delta method to calculate the variance, standard error, Wald test statistic, etc., of the transformations. \texttt{nlcom} is designed for functions of the parameters, and \texttt{predictnl} is designed for functions of the parameters and of the data, that is, for predictions.

\texttt{nlcom} generalizes \texttt{lincom} (see [R] \texttt{lincom}) in two ways. First, \texttt{nlcom} allows the transformations to be nonlinear. Second, \texttt{nlcom} can be used to simultaneously estimate many transformations (whether linear or nonlinear) and to obtain the estimated variance–covariance matrix of these transformations.
Basics

In [R] lincom, the following regression was performed:

```
. use http://www.stata-press.com/data/r14/regress
. regress y x1 x2 x3
```

<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>Number of obs = 148</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model</td>
<td>3259.3561</td>
<td>3</td>
<td>1086.45203</td>
<td>Prob &gt; F = 0.0000</td>
</tr>
<tr>
<td>Residual</td>
<td>1627.56282</td>
<td>144</td>
<td>11.3025196</td>
<td>R-squared = 0.6670</td>
</tr>
<tr>
<td>Total</td>
<td>4886.91892</td>
<td>147</td>
<td>33.2443464</td>
<td>Adj R-squared = 0.6600</td>
</tr>
<tr>
<td></td>
<td>Root MSE = 3.3619</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```
y  | Coef.  | Std. Err. | t   | P>|t|  | [95% Conf. Interval]  
x1  | 1.457113 | 1.07461 | 1.36 | 0.177 | -.666934 3.581161 
x2  | 2.221682 | .8610358 | 2.58 | 0.011 | .5197797 3.923583 
x3  | -.006139 | .0005543 | -11.08 | 0.000 | -.0072345 -.0050435 
_cons | 36.10135 | 4.382693 | 8.24 | 0.000 | 27.43863 44.76407 |
```

Then lincom was used to estimate the difference between the coefficients of x1 and x2:

```
. lincom _b[x2] - _b[x1]
   ( 1)  - x1 + x2 = 0
```

| y  | Coef.  | Std. Err. | t   | P>|t|  | [95% Conf. Interval]  
(1)  | .7645682 | .9950282 | 0.77 | 0.444 | -1.20218 2.731316 |

It was noted, however, that nonlinear expressions are not allowed with lincom:

```
. lincom _b[x2]/_b[x1]
   not possible with test r(131);
```

Nonlinear transformations are instead estimated using nlcom:

```
. nlcom _b[x2]/_b[x1]
   _nl_1: _b[x2]/_b[x1]
```

| y  | Coef.  | Std. Err. | z   | P>|z|  | [95% Conf. Interval]  
_nl_1 | 1.524714 | .9812848 | 1.55 | 0.120 | -.3985686 3.447997 |

Technical note

The notation _b[name] is the standard way in Stata to refer to regression coefficients; see [U] 13.5 Accessing coefficients and standard errors. Some commands, such as lincom and test, allow you to drop the _b[] and just refer to the coefficients by name. nlcom, however, requires the full specification _b[name].
Returning to our linear regression example, `nlcom` also allows simultaneous estimation of more than one combination:

```stata
    . nlcom (_b[x2]/_b[x1]) (_b[x3]/_b[x1]) (_b[x3]/_b[x2])
    _nl_1: _b[x2]/_b[x1]
    _nl_2: _b[x3]/_b[x1]
    _nl_3: _b[x3]/_b[x2]
```

We can also label the transformations to produce more informative names in the estimation table:

```stata
    . nlcom (ratio21:_b[x2]/_b[x1]) (ratio31:_b[x3]/_b[x1]) (ratio32:_b[x3]/_b[x2])
    ratio21: _b[x2]/_b[x1]
    ratio31: _b[x3]/_b[x1]
    ratio32: _b[x3]/_b[x2]
```

`nlcom` stores the vector of estimated combinations and its estimated variance–covariance matrix in `r()`:

```stata
    . matrix list r(b)
    r(b)[1,3]
        ratio21  ratio31  ratio32
    c1  1.5247143  -0.00421315  -0.00276324
    . matrix list r(V)
    symmetric r(V)[3,3]
        ratio21  ratio31  ratio32
    ratio21  .96291982  .0033483  2.137e-06
    ratio31  -.00287781  .00001121  1.144e-06
    ratio32  -.00014234  2.137e-06  1.144e-06
```
Using the post option

When used with the post option, `nlcom` stores the estimation vector and variance–covariance matrix in `e()`, making the transformation permanent:

```
. quietly nlcom (ratio21:_b[x2]/_b[x1]) (ratio31:_b[x3]/_b[x1])
> (ratio32:_b[x3]/_b[x2]), post
. matrix list e(b)
   e(b)[1,3]
   ratio21    ratio31    ratio32
   y1    1.5247143 -.00421315 -.00276324
   . matrix list e(V)
   symmetric e(V)[3,3]
   ratio21   ratio31    ratio32
   ratio21  1.26701982
   ratio31  -.00287781  .00001121
   ratio32  -.00014234  2.137e-06  1.144e-06
```

After posting, we can proceed as if we had just run a Stata estimation (`eclass`) command. For instance, we can replay the results,

```
. nlcom
   y   Coef. Std. Err. z  P>|z|  [95% Conf. Interval]
   ratio21  1.524714  .9812848  1.55 0.120  -.3985686  3.447997
   ratio31 -.0042131  .0033483 -1.26 0.208  -.0107756  .0023494
   ratio32 -.0027632  .0010695 -2.58 0.010  -.0048594  -.000667
```

or perform other postestimation tasks in the transformed metric, this time making reference to the new “coefficients”:

```
. display _b[ratio31]
   -.00421315
. estat vce, correlation
   Correlation matrix of coefficients of nlcom model
   e(V)
   ratio21   ratio31   ratio32
   ratio21  1.0000
   ratio31 -.08759  1.0000
   ratio32 -.1356  .5969  1.0000

. test _b[ratio21] = 1
   ( 1) ratio21 = 1
   chi2( 1) = 0.29
   Prob > chi2 = 0.5928
```

We see that testing `_b[ratio21]=1` in the transformed metric is equivalent to testing using `testnl _b[x2]/_b[x1]=1` in the original metric:

```
. quietly regress y x1 x2 x3
. testnl _b[x2]/_b[x1] = 1
   (1)  _b[x2]/_b[x1] = 1
   chi2( 1) = 0.29
   Prob > chi2 = 0.5928
```

We needed to refit the regression model to recover the original parameter estimates.
Technical note

In a previous technical note, we mentioned that commands such as `lincom` and `test` permit reference to `name` instead of `_b[name]`. This is not the case when `lincom` and `test` are used after `nlcom, post`. In the above, we used

```
.test _b[ratio21] = 1
```

rather than

```
.test ratio21 = 1
```

which would have returned an error. Consider this a limitation of Stata. For the shorthand notation to work, you need a variable named `name` in the data. In `nlcom`, however, `name` is just a coefficient label that does not necessarily correspond to any variable in the data.

Reparameterizing ML estimators for univariate data

When run using only a response and no covariates, Stata’s maximum likelihood (ML) estimation commands will produce ML estimates of the parameters of some assumed univariate distribution for the response. The parameterization, however, is usually not one we are used to dealing with in a nonregression setting. In such cases, `nlcom` can be used to transform the estimation results from a regression model to those from a maximum likelihood estimation of the parameters of a univariate probability distribution in a more familiar metric.

Example 1

Consider the following univariate data on $Y =$ # of traffic accidents at a certain intersection in a given year:

```
use http://www.stata-press.com/data/r14/trafint
summarize accidents
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>accidents</td>
<td>12</td>
<td>13.833</td>
<td>14.47778</td>
<td>0</td>
<td>41</td>
</tr>
</tbody>
</table>

A quick glance of the output from `summarize` leads us to quickly reject the assumption that $Y$ is distributed as Poisson because the estimated variance of $Y$ is much greater than the estimated mean of $Y$.

Instead, we choose to model the data as univariate negative binomial, of which a common parameterization is

$$
\Pr(Y = y) = \frac{\Gamma(r + y)}{\Gamma(r)\Gamma(y + 1)} p^r (1 - p)^y \quad 0 \leq p \leq 1, \quad r > 0, \quad y = 0, 1, \ldots
$$

with

$$
E(Y) = \frac{r(1 - p)}{p} \quad \text{Var}(Y) = \frac{r(1 - p)}{p^2}
$$

There exist no closed-form solutions for the maximum likelihood estimates of $p$ and $r$, yet they may be estimated by the iterative method of Newton–Raphson. One way to get these estimates would be to write our own Newton–Raphson program for the negative binomial. Another way would be to write our own ML evaluator; see `[R] ml`. 
The easiest solution, however, would be to use Stata’s existing negative binomial ML regression command, *nbreg*. The only problem with this solution is that *nbreg* estimates a different parameterization of the negative binomial, but we can worry about that later.

```
. nbreg accidents
Fitting Poisson model:
Iteration 0:  log likelihood = -105.05361
Iteration 1:  log likelihood = -105.05361
Fitting constant-only model:
Iteration 0:  log likelihood = -43.948619
Iteration 1:  log likelihood = -43.891483
Iteration 2:  log likelihood = -43.89144
Iteration 3:  log likelihood = -43.89144
Fitting full model:
Iteration 0:  log likelihood = -43.89144
Iteration 1:  log likelihood = -43.89144

Negative binomial regression

| Coef.  | Std. Err. | z   | P>|z| | [95% Conf. Interval] |
|--------|-----------|-----|------|----------------------|
| _cons  | 2.627081  | .3192233 | 8.23 | 0.000   | 2.001415 3.252747 |
| /lnalpha | .1402425  | .4187147 | -.6804233 | .9609083 |
| alpha  | 1.150553  | .4817534 | .5064026 2.61407 |
```

LR test of alpha=0: chibar2(01) = 122.32 Prob >= chibar2 = 0.000

```
. nbreg, coeflegend
Negative binomial regression

<table>
<thead>
<tr>
<th>Coef. Legend</th>
</tr>
</thead>
<tbody>
<tr>
<td>_cons 2.627081 _b[accidents:_cons]</td>
</tr>
<tr>
<td>/lnalpha .1402425 _b[lnalpha:_cons]</td>
</tr>
<tr>
<td>alpha 1.150553</td>
</tr>
</tbody>
</table>

LR test of alpha=0: chibar2(01) = 122.32 Prob >= chibar2 = 0.000
```

From this output, we see that, when used with univariate data, *nbreg* estimates a regression intercept, $\beta_0$, and the logarithm of some parameter $\alpha$. This parameterization is useful in regression models: $\beta_0$ is the intercept meant to be augmented with other terms of the linear predictor, and $\alpha$ is an overdispersion parameter used for comparison with the Poisson regression model.

However, we need to transform $(\beta_0, \ln \alpha)$ to $(p, r)$. Examining *Methods and formulas* of [R] *nbreg* reveals the transformation as

$$ p = \left(1 + \alpha \exp(\beta_0)\right)^{-1} \quad r = \alpha^{-1} $$

which we apply using *nlcom*:

```
Given the invariance of maximum likelihood estimators and the properties of the delta method, the above parameter estimates, standard errors, etc., are precisely those we would have obtained had we instead performed the Newton–Raphson optimization in the \((p, r)\) metric.

### Technical note

Note how we referred to the estimate of \(\ln\alpha\) above as \([\lnalpha]_b[\_cons]\). This is not entirely evident from the output of \texttt{nbreg}, which is why we redisplayed the results using the \texttt{coeflegend} option so that we would know how to refer to the coefficients; [U] 13.5 Accessing coefficients and standard errors.

### nlcom versus eform

Many Stata estimation commands allow you to display exponentiated regression coefficients, some by default, some optionally. Known as “eform” in Stata terminology, this reparameterization serves many uses: it gives odds ratios for logistic models, hazard ratios in survival models, incidence-rate ratios in Poisson models, and relative-risk ratios in multinomial logit models, to name a few.

For example, consider the following estimation taken directly from the technical note in [R] \texttt{poisson}:

```stata
.use http://www.stata-press.com/data/r14/airline
.generate lnN = ln(n)
.poisson injuries XYZowned lnN
```

|             | Coef.    | Std. Err. | z   | P>|z|   |   [95% Conf. Interval]     |

Prob > chi2 = 0.0001
Log likelihood = -22.332276 Pseudo R2 = 0.3001
```

| injuries    | IRR      | Std. Err. | z     | P>|z|    | [95% Conf. Interval] |
|-------------|----------|-----------|-------|--------|----------------------|
| XYZowned    | 1.981921 | .7721322  | 1.76  | 0.079  | .9235678 4.253085    |
| lnN         | 4.154402 | 1.547579  | 3.82  | 0.000  | 2.00181 8.621728     |
| _cons       | 129.5272 | 91.84126  | 6.86  | 0.000  | 32.2713 519.8828     |

we obtain the exponentiated regression coefficients and their estimated standard errors.

Contrast this with what we obtain if we exponentiate the coefficients manually by using `nlcom`:

```
.nlcom (E_XYZowned:exp(_b[XYZowned])) (E_lnN:exp(_b[lnN]))
E_XYZowned: exp(_b[XYZowned])
E_lnN: exp(_b[lnN])
```

| injuries    | Coef.    | Std. Err. | z     | P>|z|    | [95% Conf. Interval] |
|-------------|----------|-----------|-------|--------|----------------------|
| E_XYZowned  | 1.981921 | .7721322  | 2.57  | 0.010  | .4685701 3.495273    |
| E_lnN       | 4.154402 | 1.547579  | 2.68  | 0.007  | 1.121203 7.187602    |

There are three things to note when comparing `poison, irr` (and `eform` in general) with `nlcom`:

1. The exponentiated coefficients and standard errors are identical. This is certainly good news.
2. The Wald test statistic (z) and level of significance are different. When using `poison, irr` and other related `eform` options, the Wald test does not change from what you would have obtained without the `eform` option, and you can see this by comparing both versions of the `poison` output given previously.

When you use `eform`, Stata knows that what is usually desired is a test of

\[ H_0 : \exp(\beta) = 1 \]

and not the uninformative-by-comparison

\[ H_0 : \exp(\beta) = 0 \]

The test of \( H_0 : \exp(\beta) = 1 \) is asymptotically equivalent to a test of \( H_0 : \beta = 0 \), the Wald test in the original metric, but the latter has better small-sample properties. Thus if you specify `eform`, you get a test of \( H_0 : \beta = 0 \).

`nlcom`, however, is general. It does not attempt to infer the test of greatest interest for a given transformation, and so a test of

\[ H_0 : \text{transformed coefficient} = 0 \]

is always given, regardless of the transformation.

3. You may be surprised to see that, even though the coefficients and standard errors are identical, the confidence intervals (both 95%) are different.
Eform confidence intervals are standard confidence intervals with the endpoints transformed. For example, the confidence interval for the coefficient on $\ln N$ is $[0.694, 2.154]$, whereas the confidence interval for the incidence-rate ratio due to $\ln N$ is $[\exp(0.694), \exp(2.154)] = [2.002, 8.619]$, which, except for some roundoff error, is what we see from the output of `poisson, irr`. For exponentiated coefficients, confidence intervals based on transform-the-endpoints methodology generally have better small-sample properties than their asymptotically equivalent counterparts.

The transform-the-endpoints method, however, gives valid coverage only when the transformation is monotonic. `nlcom` uses a more general and asymptotically equivalent method for calculating confidence intervals, as described in Methods and formulas.

**Stored results**

`nlcom` stores the following in `r()`:

Scalars
- `r(N)` number of observations
- `r(df_r)` residual degrees of freedom

Matrices
- `r(b)` vector of transformed coefficients
- `r(V)` estimated variance–covariance matrix of the transformed coefficients

If `post` is specified, `nlcom` also stores the following in `e()`:

Scalars
- `e(N)` number of observations
- `e(df_r)` residual degrees of freedom
- `e(N_strata)` number of strata $L$, if used after `svy`
- `e(N_psu)` number of sampled PSUs $n$, if used after `svy`
- `e(rank)` rank of `e(V)`

Macros
- `e(cmd)` `nlcom`
- `e(predict)` program used to implement `predict`
- `e(properties)` `b V`

Matrices
- `e(b)` vector of transformed coefficients
- `e(V)` estimated variance–covariance matrix of the transformed coefficients
- `e(V_srs)` simple-random-sampling-without-replacement (co)variance $\hat{V}_{srs,wr}$, if `svy`
- `e(V_srsrw)` simple-random-sampling-with-replacement (co)variance $\hat{V}_{srs,wr}$, if `svy` and `fpc()`
- `e(V_msp)` misspecification (co)variance $\hat{V}_{msp}$, if `svy` and available

Functions
- `e(sample)` marks estimation sample

**Methods and formulas**

Given a $1 \times k$ vector of parameter estimates, $\hat{\theta} = (\hat{\theta}_1, \ldots, \hat{\theta}_k)$, consider the estimated $p$-dimensional transformation

$$g(\hat{\theta}) = [g_1(\hat{\theta}), g_2(\hat{\theta}), \ldots, g_p(\hat{\theta})]$$

The estimated variance–covariance of $g(\hat{\theta})$ is given by

$$\hat{\text{Var}} \left\{ g(\hat{\theta}) \right\} = GVG'$$
where $G$ is the $p \times k$ matrix of derivatives for which

$$G_{ij} = \frac{\partial g_i(\theta)}{\partial \theta_j} \bigg|_{\theta = \hat{\theta}}$$

$i = 1, \ldots, p \quad j = 1, \ldots, k$

and $V$ is the estimated variance–covariance matrix of $\hat{\theta}$. Standard errors are obtained as the square roots of the variances.

The Wald test statistic for testing

$$H_0: g_i(\theta) = 0$$

versus the two-sided alternative is given by

$$Z_i = \frac{g_i(\hat{\theta})}{\sqrt{\text{Var}_{ii}\{g(\hat{\theta})\}}}^{1/2}$$

When the variance–covariance matrix of $\hat{\theta}$ is an asymptotic covariance matrix, $Z_i$ is approximately distributed as Gaussian. For linear regression, $Z_i$ is taken to be approximately distributed as $t_{1,r}$ where $r$ is the residual degrees of freedom from the original fitted model.

A $(1 - \alpha) \times 100\%$ confidence interval for $g_i(\theta)$ is given by

$$g_i(\hat{\theta}) \pm z_{\alpha/2} \left[ \text{Var}_{ii}\{g(\hat{\theta})\} \right]^{1/2}$$

for those cases where $Z_i$ is Gaussian and

$$g_i(\hat{\theta}) \pm t_{\alpha/2,r} \left[ \text{Var}_{ii}\{g(\hat{\theta})\} \right]^{1/2}$$

for those cases where $Z_i$ is $t$ distributed. $z_p$ is the $1 - p$ quantile of the standard normal distribution, and $t_{p,r}$ is the $1 - p$ quantile of the $t$ distribution with $r$ degrees of freedom.

nlogit performs full information maximum-likelihood estimation for nested logit models. These models relax the assumption of independently distributed errors and the independence of irrelevant alternatives inherent in conditional and multinomial logit models by clustering similar alternatives into nests.

By default, nlogit uses a parameterization that is consistent with random utility maximization (RUM). Before version 10 of Stata, a nonnormalized version of the nested logit model was fit, which you can request by specifying the nonnormalized option.

You must use nlogitgen to generate a new categorical variable to specify the branches of the decision tree before calling nlogit.

**Quick start**

Create variables identifying alternatives at higher levels

For a three-level nesting structure, create 12alt identifying four alternatives at level two based on the variable balt which identifies eight bottom-level alternatives

```
nlogitgen 12alt = balt(12alt1: balt1 | balt2, 12alt2: balt3 | balt4, ///
                  12alt3: balt5 | balt6, 12alt4: balt7 | balt8)
```

Same as above, defining 12alt from values of balt rather than from value labels

```
nlogitgen 12alt = balt(12alt1: 1|2, 12alt2: 3|4, 12alt3: 5|6, ///
                  12alt4: 7|8)
```

Create talt identifying top-level alternatives based on the four alternatives in 12alt

```
nlogitgen talt = 12alt(talt1: 12alt1 | 12alt2, talt2: 1talt3 | 12alt4)
```

Examine tree structure

Display three-level nesting structure

```
nlogittree balt 12alt talt
```

Also report choice frequencies of indicator chosen for each bottom-level alternative

```
nlogittree balt 12alt talt, choice(chosen)
```

Identify potentially problematic observations before fitting the model by specifying case identifier casevar

```
nlogittree balt 12alt talt, choice(chosen) case(casevar)
```

1712
As above, and generate prob indicating problematic observations

\[ \text{nlogittree balt l2alt talt, choice(chosen) case(casevar) generate(prob)} \]

**Fit nested logit model**

Three-level model with alternative-specific covariate \( x_1 \), case-specific covariate \( x_2 \) modeling top-level choice, and case-specific covariate \( x_3 \) modeling level-two choice

\[ \text{nlogit chosen x1 || talt: x2 || l2alt: x3 || balt:, case(casevar)} \]

As above, but do not estimate intercepts for bottom-level alternatives

\[ \text{nlogit chosen x1 || talt: x2 || l2alt: x3 || balt:, noconstant /// case(casevar)} \]

As above, but estimate intercepts for top-level alternatives

\[ \text{nlogit chosen x1 || talt: x2, estconst || l2alt: x3 || balt:, noconstant case(casevar)} \]

Specify the base alternative at each level

\[ \text{nlogit chosen x1 || talt: x2, base(talt2) || l2alt: x3, base(l2alt4) || balt:, base(balt8) case(casevar)} \]

Use nonnormalized parameterization

\[ \text{nlogit chosen x1 || talt: x2 || l2alt: x3 || balt:, case(casevar) /// nonnormalized} \]

*byaltvarlist* may contain factor variables; see [U] 11.4.3 Factor variables.

bootstrap, by, fp, jackknife, and statsby are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

fweights, iweights, and pweights are allowed with nlogit, and fweights are allowed with nlogittree; see [U] 11.1.6 weight. Weights for nlogit must be constant within case.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
Options

Specification and options for lev#_equation

`altvar` is a variable identifying alternatives at this level of the hierarchy.

`byaltvarlist` specifies the variables to be used to compute the by-alternative regression coefficients for that level. For each variable specified in the variable list, there will be one regression coefficient for each alternative of that level of the hierarchy. If the variable is constant across each alternative (a case-specific variable), the regression coefficient associated with the base alternative is not identifiable. These regression coefficients are labeled as (base) in the regression table. If the variable varies among the alternatives, a regression coefficient is estimated for each alternative.

`base(# | lbl)` can be specified in each level equation where it identifies the base alternative to be used at that level. The default is the alternative that has the highest frequency.

If `vce(bootstrap)` or `vce(jackknife)` is specified, you must specify the base alternative for each level that has a `byaltvarlist` or if the constants will be estimated. Doing so ensures that the same model is fit with each call to `nlogit`.

`estconst` applies to all the level equations except the bottom-level equation. Specifying `estconst` requests that constants for each alternative (except the base alternative) be estimated. By default, no constant is estimated at these levels. Constants can be estimated in only one level of the tree hierarchy. If you specify `estconst` for one of the level equations, you must specify `noconstant` for the bottom-level equation.

Options for `nlogit`

`case(varname)` specifies the variable that identifies each case. `case()` is required.

`base(# | lbl)` can be specified in each level equation where it identifies the base alternative to be used at that level. The default is the alternative that has the highest frequency.

If `vce(bootstrap)` or `vce(jackknife)` is specified, you must specify the base alternative for each level that has a `byaltvarlist` or if the constants will be estimated. Doing so ensures that the same model is fit with each call to `nlogit`.

`noconstant` applies only to the equation defining the bottom level of the hierarchy. By default, constants are estimated for each alternative of `altvar`, less the base alternative. To suppress the constant terms for this level, specify `noconstant`. If you do not specify `noconstant`, you cannot specify `estconst` for the higher-level equations.

`nonnormalized` requests a nonnormalized parameterization of the model that does not scale the inclusive values by the degree of dissimilarity of the alternatives within each nest. Use this option to replicate results from older versions of Stata. The default is to use the RUM–consistent parameterization.

`altwise` specifies that alternativewise deletion be used when marking out observations because of missing values in your variables. The default is to use casewise deletion. This option does not apply to observations that are marked out by the `if` or in qualifier or the by prefix.
constraints(\texttt{constraints}); see [\texttt{R} \ estimation \ options].

The inclusive-valued/dissimilarity parameters are parameterized as \texttt{ml} ancillary parameters. They are labeled as \texttt{[alternative\_tau]\_const}, where \texttt{alternative} is one of the alternatives defining a branch in the tree. To constrain the inclusive-valued/dissimilarity parameter for alternative \texttt{a1} to be, say, equal to alternative \texttt{a2}, you would use the following syntax:

\begin{verbatim}
   . constraint 1 [a1\_tau]_cons = [a2\_tau]_cons
   . nlogit ..., constraints(1)
\end{verbatim}

collinear prevents collinear variables from being dropped. Use this option when you know that you have collinear variables and you are applying \texttt{constraints()} to handle the rank reduction. See [\texttt{R} \ estimation \ options] for details on using \texttt{collinear} with \texttt{constraints()}.

\texttt{nlogit} will not allow you to specify an independent variable in more than one level equation. Specifying the \texttt{collinear} option will allow execution to proceed in this case, but it is your responsibility to ensure that the parameters are identified.

\texttt{vce(\texttt{vcetype})} specifies the type of standard error reported, which includes types that are derived from asymptotic theory (\texttt{oim}), that are robust to some kinds of misspecification (\texttt{robust}), that allow for intragroup correlation (\texttt{cluster \texttt{clustvar}}), and that use bootstrap or jackknife methods (\texttt{bootstrap}, \texttt{jackknife}); see [\texttt{R} \ \texttt{vce \ option}].

If \texttt{vce(\texttt{robust})} or \texttt{vce(\texttt{cluster \texttt{clustvar}})} is specified, the likelihood-ratio test for the independence of irrelevant alternatives (IIA) is not computed.

\texttt{level(#)}; see [\texttt{R} \ \texttt{estimation \ options}].

\texttt{notree} specifies that the tree structure of the nested logit model not be displayed. See also \texttt{nolabel} and \texttt{nobranches} below for when \texttt{notree} is not specified.

\texttt{nocnsreport}; see [\texttt{R} \ \texttt{estimation \ options}].

\texttt{display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, alllbaselevels, nolabel, fvwrap(#), fvwrappon(style), cformat(\%fmt), pformat(\%fmt), sformat(\%fmt), and nolstretch}; see [\texttt{R} \ \texttt{estimation \ options}].

\texttt{Maximization}

\texttt{maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init\_specs)}; see [\texttt{R} \ \texttt{maximize}]. These options are seldom used. The \texttt{technique(bhhh)} option is not allowed.

\textbf{Specification and options for nlogitgen}

\texttt{newaltvar} and \texttt{altvar} are variables identifying alternatives at each level of the hierarchy.

\texttt{label} defines a label to associate with the branch. If no label is given, a numeric value is used.

\texttt{alternative} specifies an alternative, of \texttt{altvar} specified in the syntax, to be included in the branch. It is either a numeric value or the label associated with that value. An example of \texttt{nlogitgen} is

\begin{verbatim}
   . nlogitgen type = restaurant(fast: 1 | 2, > family: CafeEccell | LosNortenos | WingsNmore, fancy: 6 | 7)
\end{verbatim}

\texttt{nolog} suppresses the display of the iteration log.
Specification and options for nlogittree

`altvarlist` is a list of alternative variables that define the tree hierarchy. The first variable must define bottom-level alternatives, and the order continues to the variable defining the top-level alternatives.

`choice(depvar)` defines the choice indicator variable and forces `nlogittree` to compute and display choice frequencies for each bottom-level alternative.

`case(varname)` specifies the variable that identifies each case. When both `case()` and `choice()` are specified, `nlogittree` executes diagnostics on the tree structure and identifies observations that will cause `nlogit` to terminate execution or drop observations.

`generate(newvar)` generates a new indicator variable, `newvar`, that is equal to 1 for invalid observations. This option requires that both `choice()` and `case()` are also specified.

`nolabel` forces `nlogittree` to suppress value labels in tree-structure output.

`nobranches` forces `nlogittree` to suppress drawing branches in the tree-structure output.

Remarks and examples

Remarks are presented under the following headings:

- **Introduction**
- **Data setup and the tree structure**
- **Estimation**
- **Testing for the IIA**
- **Nonnormalized model**

**Introduction**

`nlogit` performs full information maximum-likelihood estimation for nested logit models. These models relax the assumption of independently distributed errors and the IIA inherent in conditional and multinomial logit models by clustering similar alternatives into nests. Because the nested logit model is a direct generalization of the alternative-specific conditional logit model (also known as McFadden’s choice model), you may want to read [R] `asclogit` before continuing.

By default, `nlogit` uses a parameterization that is consistent with RUM. Before version 10 of Stata, a nonnormalized version of the nested logit model was fit, which you can request by specifying the `nonnormalized` option. We recommend using the RUM-consistent version of the model for new projects because it is based on a sound model of consumer behavior.

McFadden (1977, 1981) showed how this model can be derived from a rational choice framework. Amemiya (1985, chap. 9) contains a nice discussion of how this model can be derived under the assumption of utility maximization. Hensher, Rose, and Greene (2005) provide a lucid introduction to choice models including nested logit.

Throughout this entry, we consider a model of restaurant choice. We begin by introducing the data.

**Example 1**

We have fictional data on 300 families and their choice of seven local restaurants. Freebirds and Mama’s Pizza are fast food restaurants; Café Eccell, Los Nortenios, and Wings ‘N More are family restaurants; and Christopher’s and Mad Cows are fancy restaurants. We want to model the decision
of where to eat as a function of household income (income, in thousands of dollars), the number of children in the household (kids), the rating of the restaurant according to a local restaurant guide (rating, coded 0–5), the average meal cost per person (cost), and the distance between the household and the restaurant (distance, in miles). income and kids are attributes of the family, rating is an attribute of the alternative (the restaurant), and cost and distance are attributes of the alternative as perceived by the families—that is, each family has its own cost and distance for each restaurant.

We begin by loading the data and listing some of the variables for the first three families:

```stata

Sorted by: family_id
Because each family chose among seven restaurants, there are 7 observations in the dataset for each family. The variable chosen is coded 0/1, with 1 indicating the chosen restaurant and 0 otherwise.

We could fit a conditional logit model to our data. Because income and kids are constant within each family, we would use the asclogit command instead of clogit. However, the conditional logit may be inappropriate. That model assumes that the random errors are independent, and as a result it forces the odds ratio of any two alternatives to be independent of the other alternatives, a property known as the IIA. We will discuss the IIA assumption in more detail later.

Assuming that unobserved shocks influencing a decision maker’s attitude toward one alternative have no effect on his attitudes toward the other alternatives may seem innocuous, but often this assumption is too restrictive. Suppose that when a family was deciding which restaurant to visit, they were pressed for time because of plans to attend a movie later. The unobserved shock (being in a hurry) would raise the likelihood that the family goes to either fast food restaurant (Freebirds or Mama’s Pizza). Similarly, another family might be choosing a restaurant to celebrate a birthday and therefore be inclined to attend a fancy restaurant (Christopher’s or Mad Cows).

Nested logit models relax the independence assumption and allow us to group alternatives for which unobserved shocks may have concomitant effects. Here we suspect that restaurants should be grouped by type (fast, family, or fancy). The tree structure of a family’s decision about where to eat might look like this:
At the bottom of the tree are the individual restaurants, indicating that there are some random shocks that affect a family’s decision to eat at each restaurant independently. Above the restaurants are the three types of restaurants, indicating that other random shocks affect the type of restaurant chosen. As is customary when drawing decision trees, at the top level is one box, representing the family making the decision.

We use the following terms to describe nested logit models.

**level**, or decision level, is the level or stage at which a decision is made. The example above has only two levels. In the first level, a type of restaurant is chosen—fast food, family, or fancy—and in the second level, a specific restaurant is chosen.

**bottom level** is the level where the final decision is made. In our example, this is when we choose a specific restaurant.

**alternative set** is the set of all possible alternatives at any given decision level.

**bottom alternative set** is the set of all possible alternatives at the bottom level. This concept is often referred to as the choice set in the economics-choice literature. In our example, the bottom alternative set is all seven of the specific restaurants.

**alternative** is a specific alternative within an alternative set. In the first level of our example, “fast food” is an alternative. In the second or bottom level, “Mad Cows” is an alternative. Not all alternatives within an alternative set are available to someone making a choice at a specific stage, only those that are nested within all higher-level decisions.

**chosen alternative** is the alternative from an alternative set that we observe someone having chosen.

---

**Technical note**

Although decision trees in nested logit analysis are often interpreted as implying that the highest-level decisions are made first, followed by decisions at lower levels, and finally the decision among alternatives at the bottom level, no such temporal ordering is implied. See Hensher, Rose, and Greene (2005, chap. 13). In our example, we are not assuming that families first choose whether to attend a fast, family, or fancy restaurant and then choose the particular restaurant; we assume merely that they choose one of the seven restaurants.
Data setup and the tree structure

To fit a nested logit model, you must first create a variable that defines the structure of your decision tree.

Example 2

To run `nlogit`, we need to generate a categorical variable that identifies the first-level set of alternatives: fast food, family restaurants, or fancy restaurants. We can do so easily by using `nlogitgen`.

```
.nlogitgen type = restaurant(fast: Freebirds | MamasPizza, > family: CafeEccell | LosNortenos| WingsNmore, fancy: Christophers | MadCows)
new variable type is generated with 3 groups
label list lb_type
lb_type:
  1 fast
  2 family
  3 fancy

.nlogittree restaurant type, choice(chosen)
tree structure specified for the nested logit model

<table>
<thead>
<tr>
<th>type</th>
<th>N</th>
<th>restaurant</th>
<th>N</th>
<th>k</th>
</tr>
</thead>
<tbody>
<tr>
<td>fast</td>
<td>600</td>
<td>Freebirds</td>
<td>300</td>
<td>12</td>
</tr>
<tr>
<td></td>
<td></td>
<td>MamasPizza</td>
<td>300</td>
<td>15</td>
</tr>
<tr>
<td>family</td>
<td>900</td>
<td>CafeEccell</td>
<td>300</td>
<td>78</td>
</tr>
<tr>
<td></td>
<td></td>
<td>LosNortenos</td>
<td>300</td>
<td>75</td>
</tr>
<tr>
<td></td>
<td></td>
<td>WingsNmore</td>
<td>300</td>
<td>69</td>
</tr>
<tr>
<td>fancy</td>
<td>600</td>
<td>Christophers</td>
<td>300</td>
<td>27</td>
</tr>
<tr>
<td></td>
<td></td>
<td>MadCows</td>
<td>300</td>
<td>24</td>
</tr>
</tbody>
</table>

k = number of times alternative is chosen
N = number of observations at each level
```

The new categorical variable is `type`, which takes on value 1 (fast) if `restaurant` is Freebirds or Mama's Pizza; value 2 (family) if `restaurant` is Café Eccell, Los Nortenos, or Wings 'N More; and value 3 (fancy) otherwise. `nlogittree` displays the tree structure.

Technical note

We could also use values instead of value labels of `restaurant` in `nlogitgen`. Value labels are optional, and the default value labels for `type` are `type1`, `type2`, and `type3`. The vertical bar is also optional.

```
.use http://www.stata-press.com/data/r14/restaurant, clear
.nlogitgen type = restaurant(1 2, 3 4 5, 6 7)
new variable type is generated with 3 groups
label list lb_type
lb_type:
  1 type1
  2 type2
  3 type3
```

</tbody>
</table>

N = number of observations at each level

In our dataset, every family was able to choose among all seven restaurants. However, in other applications some decision makers may not have been able to choose among all possible alternatives. For example, two cases may have choice hierarchies of

<table>
<thead>
<tr>
<th>case 1</th>
<th>case 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>restaurant</td>
</tr>
<tr>
<td>restaurant</td>
<td></td>
</tr>
<tr>
<td>family</td>
<td>CafeEccell</td>
</tr>
<tr>
<td></td>
<td>LosNortenos</td>
</tr>
<tr>
<td>fancy</td>
<td>Christophers</td>
</tr>
<tr>
<td></td>
<td>MadCows</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

where the second case does not have the restaurant alternatives Café Eccell or Mad Cows available to them. The only restriction is that the relationships between higher- and lower-level alternative sets be the same for all decision makers. In this two-level example, Freebirds and Mama's Pizza are classified as fast food restaurants for both cases; Café Eccell, Los Nortenos, and Wings 'N More are family restaurants; and Christopher's and Mad Cows are fancy restaurants. nlogit requires only that hierarchy be maintained for all cases.

**Estimation**

**Example 3**

With our type variable created that defines the three types of restaurants, we can now examine how the alternative-specific attributes (cost, rating, and distance) apply to the bottom alternative set (the seven restaurants) and how family-specific attributes (income and kid) apply to the alternative set at the first decision level (the three types of restaurants).
. use http://www.stata-press.com/data/r14/restaurant, clear
. qui nlogitgen type = restaurant(fast: Freebirds | MamasPizza, > family: CafeEccell | LosNortenos| WingsNmore, fancy: Christophers | MadCows)
. nlogit chosen cost rating distance || type: income kids, base(family) || > restaurant:, noconstant case(family_id)

LR test for IIA (tau=1): chi2(3) = 6.87
Prob > chi2 = 0.0762
First, let’s examine how we called \texttt{nlogit}. The delimiters (||) separate equations. The first equation specifies the dependent variable, \texttt{chosen}, and three alternative-specific variables, \texttt{cost}, \texttt{rating}, and \texttt{distance}. We refer to these variables as alternative-specific because they vary among the bottom-level alternatives, the restaurants. We obtain one parameter estimate for each variable. These estimates are listed in the equation subtable labeled \texttt{restaurant}.

For the second equation, we specify the \texttt{type} variable. It identifies the first-level alternatives, the restaurant types. Following the colon after \texttt{type}, we specify two case-specific variables, \texttt{income} and \texttt{kids}. Here we obtain a parameter estimate for each variable for each alternative at this level. That is why we call these variable lists \texttt{by-alternative} variables. Because \texttt{income} and \texttt{kids} do not vary within each case, to identify the model one alternative’s set of parameters must be set to zero. We specified the \texttt{base(family)} option with this equation to restrict the parameters for the \texttt{family} alternative.

The variable identifying the bottom-level alternatives, \texttt{restaurant}, is specified after the second equation delimiter. We do not specify any variables after the colon delimiter at this level. Had we specified variables here, we would have obtained an estimate for each variable in each equation. As we will see below, these variables parameterize the constant term in the utility equation for each bottom-level alternative. The \texttt{noconstant} option suppresses bottom-level alternative-specific constant terms.

Near the bottom of the output are the dissimilarity parameters, which measure the degree of correlation of random shocks within each of the three types of restaurants. Dissimilarity parameters greater than one imply that the model is inconsistent with RUM; Hensher, Rose, and Greene (2005, sec. 13.6) discuss this in detail. We will ignore the fact that all our dissimilarity parameters exceed one.

The conditional logit model is a special case of nested logit in which all the dissimilarity parameters are equal to one. At the bottom of the output, we find a likelihood-ratio test of this hypothesis. Here we have mixed evidence of the null hypothesis that all the parameters are one. Equivalently, the property known as the IIA imposed by the conditional logit model holds if and only if all dissimilarity parameters are equal to one. We discuss the IIA in more detail now.

\section*{Testing for the IIA}

The IIA is a property of the multinomial and conditional logit models that forces the odds of choosing one alternative over another to be independent of the other alternatives. For simplicity, suppose that a family was choosing only between Freebirds and Mama’s Pizza, and the family was equally likely to choose either of the restaurants. The probability of going to each restaurant is 50\%. Now suppose that Bill’s Burritos opens up next door to Freebirds, which is also a burrito restaurant. If the IIA holds, then the probability of going to each restaurant must now be 33.33\% so that the family remains equally likely to go to Mama’s Pizza or Freebirds.

The IIA may sometimes be a plausible assumption. However, a more likely scenario would be for the probability of going to Mama’s Pizza to remain at 50\% and the probabilities of going to Freebirds and Bill’s Burritos to be 25\% each, because the two restaurants are next door to each other and serve the same food. Nested logit analysis would allow us to relax the IIA assumption of conditional logit. We could group Bill’s Burritos and Freebirds into one nest that encompasses all burrito restaurants and create a second nest for pizzerias.

The IIA is a consequence of assuming that the errors are independent and identically distributed (i.i.d.). Because the errors are i.i.d., they cannot contain any alternative-specific unobserved information, and therefore adding a new alternative cannot affect the relationship between a pair of existing alternatives.
In the previous example, we saw that a joint test that the dissimilarity parameters were equal to one is one way to test for IIA. However, that test required us to specify a decision tree for the nested logit model, and different specifications could lead to conflicting results of the test. Hausman and McFadden (1984) suggest that if part of the choice set truly is irrelevant with respect to the other alternatives, omitting that subset from the conditional logit model will not lead to inconsistent estimates. Therefore, Hausman’s (1978) specification test can be used to test for IIA, and this test will not be sensitive to the tree structure we specify for a nested logit model.

Example 4

We want to test the IIA for the subset of family restaurants against the alternatives of fast food and fancy restaurants. To do so, we need to use Stata’s `hausman` command; see \[ R \] `hausman`.

We first run the estimation on the full bottom alternative set, store the results by using `estimates store`, and then run the estimation on the bottom alternative set, excluding the alternatives of family restaurants. We then run the `hausman` test.

b = consistent under Ho and Ha; obtained from clogit
B = inconsistent under Ha, efficient under Ho; obtained from clogit

Test: Ho: difference in coefficients not systematic

\[ \text{chi2}(5) = (b-B)'[(V_b-V_B)^{-1}](b-B) \]

= 10.70

Prob>chi2 = 0.0577

(V_b-V_B is not positive definite)

Similar to our findings in example 3, the results of the test of the IIA are mixed. We cannot reject the IIA at the commonly used 5% significance level, but we could at the 10% level. Substantively, a significant test result suggests that the odds of going to one of the fancy restaurants versus going to one of the fast food restaurants changes if we include the family restaurants in the alternative set and that a nested logit specification may be warranted.

Nonnormalized model

Previous versions of Stata fit a nonnormalized nested logit model that is available via the nonnormalized option. The nonnormalized version is presented in, for example, Greene (2012, 768–770). Here we outline the differences between the RUM-consistent and nonnormalized models. Our discussion follows Heiss (2002) and assumes the decision tree has two levels, with M alternatives at the upper level and a total of J alternatives at the bottom level.

In a RUM framework, by consuming alternative j, decision maker i obtains utility

\[ U_{ij} = V_{ij} + \epsilon_{ij} = \alpha_j + x_{ij}\beta_j + z_i\gamma_j + \epsilon_{ij} \]

where \( V_{ij} \) is the deterministic part of utility and \( \epsilon_{ij} \) is the random part. \( x_{ij} \) are alternative-specific variables and \( z_i \) are case-specific variables. The set of errors \( \epsilon_{i1}, \ldots, \epsilon_{iJ} \) are assumed to follow the generalized extreme-value (GEV) distribution, which is a generalization of the type 1 extreme-value distribution that allows for alternatives within nests of the tree structure to be correlated. Let \( \rho_m \) denote the correlation in nest \( m \), and define the dissimilarity parameter \( \tau_m = \sqrt{1 - \rho_m} \). \( \tau_m = 0 \) implies that the alternatives in nest \( m \) are perfectly correlated, whereas \( \tau_m = 1 \) implies independence.

The inclusive value for the \( m \)th nest corresponds to the expected value of the utility that decision maker \( i \) obtains by consuming an alternative in nest \( m \). Denote this value by \( IV_m \):

\[ IV_m = \ln \sum_{j \in B_m} \exp(V_j/\tau_m) \]

where \( B_m \) denotes the set of alternatives in nest \( m \). Given the inclusive values, we can show that the probability that random-utility–maximizing decision maker \( i \) chooses alternative \( j \) is

\[ \Pr_j = \frac{\exp(V_j/\tau(j)) \exp(\tau(j)IV(j))}{\exp(IV(j)) \sum_m \exp(\tau_m IV_m)} \]
where $\tau(j)$ and $\text{IV}(j)$ are the dissimilarity parameter and inclusive value for the nest in which alternative $j$ lies.

In contrast, for the nonnormalized model, we have a latent variable

$$\tilde{V}_{i,j} = \tilde{\alpha}_j + x_{i,j} \tilde{\beta}_j + z_{i} \tilde{\gamma}_j$$

and corresponding inclusive values

$$\text{IV}_m = \ln \sum_{j \in B_m} \exp(\tilde{V}_k) \quad (2)$$

The probability of choosing alternative $j$ is

$$\Pr_j = \frac{\exp(\tilde{V}_j) \exp\{\tau(j)\text{IV}(j)\}}{\exp\{\text{IV}(j)\} \sum_m \exp(\tau_m \text{IV}_m)}$$

Equations (1) and (2) represent the key difference between the RUM-consistent and nonnormalized models. By scaling the $V_{ij}$ within each nest, the RUM-consistent model allows utilities to be compared across nests. Without the rescaling, utilities can be compared only for goods within the same nest. Moreover, adding a constant to each $V_{ij}$ for consumer $i$ will not affect the probabilities of the RUM-consistent model, but adding a constant to each $\tilde{V}_{ij}$ will affect the probabilities from the nonnormalized model. Decisions based on utility maximization can depend only on utility differences and not the scale or zero point of the utility function because utility is an ordinal concept, so the nonnormalized model cannot be consistent with utility maximization.

Heiss (2002) showed that the nonnormalized model can be RUM consistent in the special case where all the variables are specified in the bottom-level equation. Then multiplying the nonnormalized coefficients by the respective dissimilarity parameters results in the RUM-consistent coefficients.

---

### Technical note

Degenerate nests occur when there is only one alternative in a branch of the tree hierarchy. The associated dissimilarity parameter of the RUM model is not defined. The inclusive-valued parameter of the nonnormalized model will be identifiable if there are alternative-specific variables specified in (1) of the model specification (the $\text{indepvars}$ in the model syntax). Numerically, you can skirt the issue of nonidentifiable/undefined parameters by setting constraints on them. For the RUM model constraint, set the dissimilarity parameter to 1. See the description of $\text{constraints()}$ in $\text{Options}$ for details on setting constraints on the dissimilarity parameters.
Stored results

\texttt{nlogit} stores the following in \texttt{e( )}:

Scalars
\begin{itemize}
  \item \texttt{e(N)} \quad \text{number of observations}
  \item \texttt{e(N_case)} \quad \text{number of cases}

  e(gradient)  gradient vector
  e(V)  variance–covariance matrix of the estimators
  e(V_modelbased)  model-based variance

Functions
  e(sample)  marks estimation sample

Methods and formulas

Methods and formulas are presented under the following headings:

Two-level nested logit model
Three-level nested logit model
Two-level nested logit model

Consider our two-level nested logit model for restaurant choice. We define $T = \{1, 2, 3\}$ to be the set of indices denoting the three restaurant types and $R_1 = \{1, 2\}$, $R_2 = \{3, 4, 5\}$, and $R_3 = \{6, 7\}$ to be the set of indices representing each restaurant within type $t \in T$. Let $C_1$ and $C_2$ be the random variables that represent the choices made for the first level, restaurant type, and second level, restaurant, of the hierarchy, where we observe the choices $C_1 = t, t \in T$, and $C_2 = j, j \in R_t$. Let $z_t$ and $x_{tj}$, for $t \in T$ and $j \in R_t$, refer to the row vectors of explanatory variables for the first-level alternatives and bottom-level alternatives for one case, respectively. We write the utilities (latent variables) as $U_{tj} = z_t \alpha_t + x_{tj} \beta_j + \epsilon_{tj} = \eta_{tj} + \epsilon_{tj}$, where $\alpha_t$ and $\beta_j$ are column vectors and the $\epsilon_{tj}$ are random disturbances. When the $x_{tj}$ are alternative specific, we can drop the indices from $\beta$, where we estimate one coefficient for each alternative in $R_t, t \in T$. These variables are specified in the first equation of the nlogit syntax (see example 3).

When the random-utility framework is used to describe the choice behavior, the alternative that is chosen is the alternative that has the highest utility. Assume for our restaurant example that we choose $\epsilon$, where it has been shown that the given choice of restaurant type $t$ reduces to the multinomial logistic function.

Another formulation of the conditional probability of choosing alternative $j$ is a multivariate version of Gumbel’s extreme-value distribution,

$$F_{R|T}(\epsilon | t) = \exp \left[ - \left\{ \sum_{m \in R_t} \exp(\epsilon_{tm}/\tau_t) \right\}^{\tau_t} \right]$$

(3)

where it has been shown that the $\epsilon_{tj}, j \in R_t$, are exchangeable with correlation $1 - \tau_t^2$, for $\tau_t \in (0, 1]$ (Kotz and Nadarajah 2000). For example, the probability of choosing Christopher’s, $j = 6$ given type $t = 3$, is

$$Pr(C_2 = 6 \mid C_1 = 3) = Pr(U_{36} - U_{37} > 0)$$

$$= Pr(\epsilon_{36} - \epsilon_{37} \leq 0)$$

$$= \int_{-\infty}^{\infty} \left\{ \int_{-\infty}^{\epsilon_{36} - \epsilon_{37}} f_{R|T}(\epsilon_{36}, \epsilon_{37}) d\epsilon_{37} \right\} d\epsilon_{36}$$

where $f = \frac{\partial F}{\partial \epsilon_{36} \partial \epsilon_{37}}$ is the joint density function of $\epsilon$ given $t$. $U_{37}$ is the utility of eating at Mad Cows, the other fancy ($t = 3$) restaurant. Amemiya (1985) demonstrates that this integral evaluates to the logistic function

$$Pr(C_2 = 6 \mid C_1 = 3) = \frac{\exp(\eta_{36}/\tau_3)}{\exp(\eta_{36}/\tau_3) + \exp(\eta_{37}/\tau_3)} = \frac{\exp(x_{36}\beta_6/\tau_3)}{\exp(x_{36}\beta_6/\tau_3) + \exp(x_{37}\beta_7/\tau_3)}$$

and in general

$$Pr(C_2 = j \mid C_1 = t) = \frac{\exp(x_{tj}\beta_j/\tau_t)}{\sum_{m \in R_t} \exp(x_{tm}\beta_m/\tau_t)}$$

(4)

Letting $\tau_t = 1$ in (3) reduces to the product of independent extreme-value distributions, and (4) reduces to the multinomial logistic function.

For the logistic function in (4), we scale the linear predictors by the dissimilarity parameters. Another formulation of the conditional probability of choosing alternative $j \in R_t$ given choice $t \in T$ is the logistic function without this normalization:
Pr(C_2 = j | C_1 = t) = \frac{\exp(x_{tj} \beta_j)}{\sum_{m \in R_t} \exp(x_{tm} \beta_m)}

and this is what is used in nlogit’s nonnormalized parameterization.

Amemiya (1985) defines the general form for the joint distribution of the \(\epsilon\)’s as

\[ F_{T,R}(\epsilon) = \exp \left\{ - \sum_{k \in T} \theta_k \left( \sum_{m \in R_k} \exp(-\epsilon_{km}/\tau_k) \right)^{\tau_k} \right\} \]

from which the probability of choice \(t, t \in T\) can be derived as

\[ Pr(C_1 = t) = \frac{\theta_t \left\{ \sum_{m \in R_t} \exp(\eta_{tm}/\tau_t) \right\}^{\tau_t}}{\sum_{k \in T} \theta_k \left\{ \sum_{m \in R_k} \exp(\eta_{km}/\tau_k) \right\}^{\tau_k}} \tag{5} \]

nlogit sets \(\theta_t = 1\). Noting that

\[ \left\{ \sum_{m \in R_t} \exp(\eta_{tm}/\tau_t) \right\}^{\tau_t} = \left\{ \sum_{m \in R_t} \exp \left( \frac{z_t \alpha_t + x_{tm} \beta_m}{\tau_t} \right) \right\}^{\tau_t} = \exp(z_t \alpha_t) \left\{ \sum_{m \in R_t} \exp \left( \frac{x_{tm} \beta_m}{\tau_t} \right) \right\}^{\tau_t} = \exp(z_t \alpha_t + \tau_t I_t) \]

we define the inclusive values \(I_t\) as

\[ I_t = \ln \left\{ \sum_{m \in R_t} \exp(x_{tm} \beta_m/\tau_t) \right\} \]

and we can view

\[ \exp(\tau_t I_t) = \left\{ \sum_{m \in R_t} \exp(x_{tm} \beta_m)^{1/\tau_t} \right\}^{\tau_t} \]

as a weighted average of the \(\exp(x_{tm} \beta_m)\), for \(m \in R_t\). For the nlogit RUM parameterization, we can express (5) as

\[ Pr(C_1 = t) = \frac{\exp(z_t \alpha_t + \tau_t I_t)}{\sum_{k \in T} \exp(z_k \alpha_k + \tau_k I_k)} \]

Next we define inclusive values for the nonnormalized model to be

\[ \tilde{I}_t = \ln \left\{ \sum_{m \in R_t} \exp(x_{tm} \beta_m) \right\} \]

and we express \(Pr(C_1 = t)\) as

\[ Pr(C_1 = t) = \frac{\exp(z_t \alpha_t + \tau_t \tilde{I}_t)}{\sum_{k \in T} \exp(z_k \alpha_k + \tau_k \tilde{I}_k)} \tag{6} \]
Equation (5) is consistent with (6) only when $\eta_{ij} = x_{ij}\beta_j$, so in general the nlogit nonnormalized model is not consistent with the RUM model.

Now assume that we have $N$ cases where we add a third subscript, $i$, to denote case $i$, $i = 1, \ldots, N$. Denote $y_{itj}$ to be a binary variable indicating the choice made by case $i$ so that for each $i$ only one $y_{itj}$ is 1 and the rest are 0 for all $t \in T$ and $j \in R_t$. The log likelihood for the two-level RUM-consistent model is

$$\log \ell = \sum_{i=1}^{N} \sum_{k \in T} \sum_{m \in R_k} y_{itj} \log \left\{ \Pr(C_{i1} = k) \Pr(C_{i2} = m | C_{i1} = k) \right\} + x_{itj}\beta_m / \tau_k - \log \left\{ \sum_{l \in R_k} \exp(x_{il}\beta_l / \tau_l) \right\}$$

The likelihood for the nonnormalized model has a similar form, replacing $I$ with $\tilde{I}$ and by not scaling $x_{ikj}\beta_j$ by $\tau_k$.

### Three-level nested logit model

Here we define a three-level nested logit model that can be generalized to the four-level and higher models. As before, let the integer set $T$ be the indices for the first level of choices. Let sets $S_t$, $t \in T$, be mutually exclusive sets of integers representing the choices of the second level of the hierarchy. Finally, let $R_j$, $j \in S_t$, be the bottom-level choices. Let $U_{tjk} = \eta_{tjk} + \epsilon_{tjk}$, $k \in R_j$, and the distribution of $\epsilon_{tjk}$ be Gumbel’s multivariate extreme value of the form

$$F(\epsilon) = \exp \left( -\sum_{t \in T} \left\{ \sum_{j \in S_t} \left\{ \sum_{k \in R_j} \exp(\eta_{tjk} / \tau_j) \right\} \right\}^{\tau_j / v_t} \right)^{v_j}$$

Let $C_1$, $C_2$, and $C_3$ represent the choice random variables for levels 1, 2, and the bottom, respectively. Then the set of conditional probabilities is

$$\Pr(C_3 = k | C_1 = t, C_2 = j) = \frac{\exp(\eta_{tjk} / \tau_j)}{\sum_{l \in R_j} \exp(\eta_{tlk} / \tau_l)}$$

$$\Pr(C_2 = j | C_1 = t) = \frac{\left\{ \sum_{k \in R_j} \exp(\eta_{tjk} / \tau_j) \right\}^{\tau_j / v_t}}{\sum_{l \in S_t} \left\{ \sum_{k \in R_l} \exp(\eta_{tlk} / \tau_l) \right\}^{\tau_l / v_t}}$$

$$\Pr(C_1 = t) = \frac{\left[ \sum_{j \in S_t} \left\{ \sum_{k \in R_j} \exp(\eta_{tjk} / \tau_j) \right\}^{\tau_j / v_l} \right]^{v_t}}{\sum_{l \in T} \left[ \sum_{j \in S_l} \left\{ \sum_{k \in R_j} \exp(\eta_{tjk} / \tau_j) \right\}^{\tau_j / v_l} \right]^{v_t}}$$
Assume that we can decompose the linear predictor as $\eta_{tjk} = z_{it} \alpha_t + u_{itj} \gamma_j + x_{itjk} \beta_k$. Here $z_{it}$, $u_{itj}$, and $x_{itjk}$ are the row vectors of explanatory variables for the first, second, and bottom levels of the hierarchy, respectively, and $\alpha_t$, $\gamma_j$, and $\beta_k$ are the corresponding column vectors of regression coefficients for $t \in T$, $j \in S_t$, and $k \in R_j$. We then can define the inclusive values for the first and second levels as

$$I_{tj} = \log \sum_{k \in R_j} \exp(x_{itjk} \beta_k / \tau_j)$$

$$J_t = \log \sum_{j \in S_t} \exp(u_{itj} \gamma_j / \nu_t + \tau_j I_{tj})$$

and rewrite the probabilities

$$\Pr(C_3 = k \mid C_1 = t, C_2 = j) = \frac{\exp(x_{itjk} \beta_k / \tau_j)}{\sum_{l \in R_j} \exp(x_{itlj} \beta_l / \tau_j)}$$

$$\Pr(C_2 = j \mid C_1 = t) = \frac{\exp(u_{itj} \gamma_j / \nu_t + \tau_j I_{tj})}{\sum_{l \in S_t} \exp(u_{itlj} \gamma_l / \nu_t + \tau_l I_{tl})}$$

$$\Pr(C_1 = t) = \frac{\exp(z_{it} \alpha_t + \nu_t I_t)}{\sum_{l \in T} \exp(z_{itl} \alpha_l + \nu_l I_l)}$$

We add a fourth index, $i$, for case and define the indicator variable $y_{itjk}$, $i = 1, \ldots, N$, to indicate the choice made by case $i$, $t \in T$, $j \in S_t$, and $k \in R_j$. The log likelihood for the `nlogit` RUM-consistent model is

$$\ell = \sum_{i=1}^{N} \sum_{t \in T} \sum_{j \in S_t} \sum_{k \in R_j} y_{itjk} \left\{ z_{it} \alpha_t + \nu_t J_{lt} - \log \left( \sum_{m \in T} z_{im} \alpha_m + \nu_m J_{im} \right) + u_{itj} \gamma_j / \nu_t + \tau_j I_{tj} - \log \left( \sum_{m \in S_t} u_{itim} \gamma_m / \nu_t + \tau_m I_{tm} \right) + x_{itjk} \beta_k / \tau_k - \sum_{m \in R_t} \exp(x_{itim} \beta_m / \tau_k) \right\}$$

and for the nonnormalized `nlogit` model the log likelihood is

$$\ell = \sum_{i=1}^{N} \sum_{t \in T} \sum_{j \in S_t} \sum_{k \in R_j} y_{itjk} \left\{ z_{it} \alpha_t + \nu_t J_{lt} - \log \left( \sum_{m \in T} z_{im} \alpha_m + \nu_m J_{im} \right) + u_{itj} \gamma_j + \tau_j I_{tj} - \log \left( \sum_{m \in S_t} u_{itim} \gamma_m + \tau_m I_{tm} \right) + x_{itjk} \beta_k - \sum_{m \in R_t} \exp(x_{itim} \beta_m) \right\}$$

Extending the model to more than three levels is straightforward, albeit notationally cumbersome.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly `Maximum likelihood estimators` and `Methods and formulas`.

# nlogit postestimation

Postestimation tools for nlogit

## Postestimation commands

The following postestimation command is of special interest after `nlogit`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>estat alternatives</code></td>
<td>alternative summary statistics</td>
</tr>
</tbody>
</table>

The following standard postestimation commands are also available:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>contrast</code></td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td><code>estat ic</code></td>
<td>Akaike’s and Schwarz’s Bayesian information criteria (AIC and BIC)</td>
</tr>
<tr>
<td><code>estat summarize</code></td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td><code>estat vce</code></td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td><code>estimates</code></td>
<td>cataloging estimation results</td>
</tr>

**predict**

**Description for predict**

`predict` creates a new variable containing predictions such as probabilities, linear predictions, conditional probabilities, and inclusive values.

**Menu for predict**

Statistics > Postestimation

**Syntax for predict**

```
predict [type] newvar [if] [in], statistic hlevel(#) altwise

predict [type] {stub* | newvarlist} [if] [in], scores
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>predicted probabilities of choosing the alternatives at all levels of the hierarchy or at level #, where # is specified by <code>hlevel(#)</code>; the default</td>
</tr>
<tr>
<td>xb</td>
<td>linear predictors for all levels of the hierarchy or at level #, where # is specified by <code>hlevel(#)</code></td>
</tr>
<tr>
<td>condp</td>
<td>predicted conditional probabilities at all levels of the hierarchy or at level #, where # is specified by <code>hlevel(#)</code></td>
</tr>
<tr>
<td>iv</td>
<td>inclusive values for levels 2, ..., e(levels) or for <code>hlevel(#)</code></td>
</tr>
</tbody>
</table>

The inclusive value for the first-level alternatives is not used in estimation; therefore, it is not calculated. These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

**Options for predict**

- **pr** calculates the probability of choosing each alternative at each level of the hierarchy. Use the `hlevel(#)` option to compute the alternative probabilities at level #. When `hlevel(#)` is not specified, `j` new variables must be given, where `j` is the number of levels, or use `stub*` to have `predict` generate `j` variables with the prefix `stub` and numbered from 1 to `j`. The `pr` option is the default and if one new variable is given, the probability of the bottom-level alternatives are computed. Otherwise, probabilities for all levels are computed and `stub*` is still valid.

- **xb** calculates the linear prediction for each alternative at each level. Use the `hlevel(#)` option to compute the linear predictor at level #. When `hlevel(#)` is not specified, `j` new variables must be given, where `j` is the number of levels, or use `stub*` to have `predict` generate `j` variables with the prefix `stub` and numbered from 1 to `j`.

- **condp** calculates the conditional probabilities for each alternative at each level. Use the `hlevel(#)` option to compute the conditional probabilities of the alternatives at level #. When `hlevel(#)` is not specified, `j` new variables must be given, where `j` is the number of levels, or use `stub*` to have `predict` generate `j` variables with the prefix `stub` and numbered from 1 to `j`. 
iv calculates the inclusive value for each alternative at each level. Use the hlevel(#) option to compute the inclusive value at level #. There is no inclusive value at level 1. If hlevel(#) is not used, $j - 1$ new variables are required, where $j$ is the number of levels, or use stub* to have predict generate $j - 1$ variables with the prefix stub and numbered from 2 to $j$. See Methods and formulas in [R] nlogit for a definition of the inclusive values.

hlevel(#) calculates the prediction only for hierarchy level #.

altwise specifies that alternativewise deletion be used when marking out observations due to missing values in your variables. The default is to use casewise deletion. The xb option always uses alternativewise deletion.

scores calculates the scores for each coefficient in $e(b)$. This option requires a new-variable list of length equal to the number of columns in $e(b)$. Otherwise, use stub* to have predict generate enumerated variables with prefix stub.

estat

Description for estat

estat alternatives displays summary statistics about the alternatives in the estimation sample for each level of the tree structure.

Menu for estat

Statistics > Postestimation

Syntax for estat

    estat alternatives

Remarks and examples

predict may be used after nlogit to obtain the predicted values of the probabilities, the conditional probabilities, the linear predictions, and the inclusive values for each level of the nested logit model. Predicted probabilities for nlogit must be interpreted carefully. Probabilities are estimated for each case as a whole and not for individual observations.

Example 1

Continuing with our model in example 3 of [R] nlogit, we refit the model and then examine a summary of the alternatives and their frequencies in the estimation sample.

[U] 20 Estimation and postestimation commands
nlsur fits a system of nonlinear equations by feasible generalized nonlinear least squares (FGNLS).

With the interactive version of the command, you enter the system of equations on the command line or in the dialog box by using substitutable expressions. If you have a system that you use regularly, you can write a substitutable expression program and use the second syntax to avoid having to reenter the system every time. The function evaluator program version gives you the most flexibility in exchange for increased complexity; with this version, your program is given a vector of parameters and a variable list, and your program computes the system of equations.

When you write a substitutable expression program or a function evaluator program, the first five letters of the name must be nlsur. sexp_prog and func_prog refer to the name of the program without the first five letters. For example, if you wrote a function evaluator program named nlsurregss, you would type nlsur regss @ ... to estimate the parameters.

Quick start

Two-parameter exponential model regressing $y_1$ on $x$ using the default FGNLS estimator

\[
\text{nlsur (} y_1 = \{b1\}*\{b2\}^x \text{)}
\]

Add the variables() option to allow for missing values of $y_1$ and $x$

\[
\text{nlsur (} y_1 = \{b1\}*\{b2\}^x \text{), variables(y1 x)}
\]

Two-equation, two-parameter exponential model

\[
\text{nlsur (} y_1 = \{b1\}*\{b2\}^x \text{) (} y_2 = \{g1\}*\{g2\}^x \text{), variables(y1 y2 x)}
\]

As above, but use the iterative FGNLS estimator

\[
\text{nlsur (} y_1 = \{b1\}*\{b2\}^x \text{) (} y_2 = \{g1\}*\{g2\}^x \text{), variables(y1 y2 x) ifgnls}
\]

Specify starting values for parameters $b_1$ and $g_2$

\[
\text{nlsur (} y_1 = \{b1=0.5\}*\{b2\}^x \text{) (} y_2 = \{g1\}*\{g2=1\}^x \text{), variables(y1 y2 x)}
\]

Same as above

\[
\text{nlsur (} y_1 = \{b1\}*\{b2\}^x \text{) (} y_2 = \{g1\}*\{g2\}^x \text{), variables(y1 y2 x) initial(b1 .5 g2 1)}
\]

As above, but specify starting values using the matrix $i$

\[
\text{matrix i = (.5,0,0,1)}
\]
\[
\text{nlsur (} y_1 = \{b1\}*\{b2\}^x \text{) (} y_2 = \{g1\}*\{g2\}^x \text{), variables(y1 y2 x) initial(i)}
\]
Syntax

Interactive version

\[ \textit{nlsur} \ (\textit{depvar}_1 = <\textit{sexp}_1>) \ (\textit{depvar}_2 = <\textit{sexp}_2>) \ldots [\textit{if}] [\textit{in}] [\textit{weight}] \ [, \textit{options}] \]

Programmed substitutable expression version

\[ \textit{nlsur} \ \textit{sexp}_\text{prog} : \ \textit{depvar}_1 \ \textit{depvar}_2 \ldots [\textit{varlist}] [\textit{if}] [\textit{in}] [\textit{weight}] \ [, \textit{options}] \]

Function evaluator program version

\[ \textit{nlsur} \ \textit{func}_\text{prog} @ \ \textit{depvar}_1 \ \textit{depvar}_2 \ldots [\textit{varlist}] [\textit{if}] [\textit{in}] [\textit{weight}] , \]
\[ \text{nequations}(\#) \{ \text{parameters}(\text{namelist}) | \text{nparameters}(\#) \} [\textit{options}] \]

where

- \( \textit{depvar}_j \) is the dependent variable for equation \( j \);
- \( <\textit{sexp}>_j \) is the substitutable expression for equation \( j \);
- \( \textit{sexp}_\text{prog} \) is a substitutable expression program; and
- \( \textit{func}_\text{prog} \) is a function evaluator program.

| delta(#)             | specify stepsize # for computing derivatives; default is delta(4e-7)       |
| noconstants          | no equations have constant terms                                            |
| hasconstants(namelist) | use *namelist* as constant terms                                           |
| coeflegend           | display legend instead of statistics                                         |

*You must specify parameters(namelist), nparameters(#), or both.

bootstrap, by, jackknife, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
aweights are not allowed with the jackknife prefix; see [R] jackknife.
aweights, fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

**Options**

<table>
<thead>
<tr>
<th>Model</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fgnls</td>
<td>requests the two-step FGNLS estimator; this is the default.</td>
</tr>
<tr>
<td>ifgnls</td>
<td>requests the iterative FGNLS estimator. For the nonlinear systems estimator, this is equivalent to maximum likelihood estimation.</td>
</tr>
</tbody>
</table>
**nls** requests the nonlinear least-squares (NLS) estimator.

`variables(varlist)` specifies the variables in the system. `nlsur` ignores observations for which any of these variables has missing values. If you do not specify `variables()`, `nlsur` issues an error message if the estimation sample contains any missing values.

`initial(initial_values)` specifies the initial values to begin the estimation. You can specify a $1 \times k$ matrix, where $k$ is the total number of parameters in the system, or you can specify a parameter name, its initial value, another parameter name, its initial value, and so on. For example, to initialize `alpha` to 1.23 and `delta` to 4.57, you would type

```
  . nlsur ..., initial(alpha 1.23 delta 4.57) ...  
```

Initial values declared using this option override any that are declared within substitutable expressions. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model. `nlsur` ignores the row and column names of the matrix.

`nequations(#)` specifies the number of equations in the system.

`parameters(namelist)` specifies the names of the parameters in the system. The names of the parameters must adhere to the naming conventions of Stata’s variables; see [U] 11.3 Naming conventions. If you specify both `parameters()` and `nparameters()`, the number of names in the former must match the number specified in the latter.

`nparameters(#)` specifies the number of parameters in the system. If you do not specify names with the `parameters()` options, `nlsur` names them `b1`, `b2`, ..., `b#`. If you specify both `parameters()` and `nparameters()`, the number of names in the former must match the number specified in the latter.

`sexp_options` refer to any options allowed by your `sexp_prog`.

`func_options` refer to any options allowed by your `func_prog`.

---

**SE/Robust**

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`gnr`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] `vce_option`.

`vce(gnr)`, the default, uses the conventionally derived variance estimator for nonlinear models fit using Gauss–Newton regression.

---

**Reporting**

`level(#)`; see [R] `estimation options`.

`title(string)` specifies an optional title that will be displayed just above the table of parameter estimates.

`title2(string)` specifies an optional subtitle that will be displayed between the title specified in `title()` and the table of parameter estimates. If `title2()` is specified but `title()` is not, `title2()` has the same effect as `title()`.

`display_options`: `noci`, `nopvalues`, `cformat(\%fmt)`, `pformat(\%fmt)`, `sformat(\%fmt)`, and `nolstretch`; see [R] `estimation options`.
Optimization

**Optimization options**: `iterate(#)`, `[no]log, trace. iterate()` specifies the maximum number of iterations to use for NLS at each round of FGNLS estimation. This option is different from `ifgnlsiterate()`, which controls the maximum rounds of FGNLS estimation to use when the `ifgnls` option is specified. `log/nolog` specifies whether to show the iteration log, and `trace` specifies that the iteration log should include the current parameter vector.

`eps(#)` specifies the convergence criterion for successive parameter estimates and for the residual sum of squares (RSS). The default is `eps(1e-5)` (0.00001). `eps()` also specifies the convergence criterion for successive parameter estimates between rounds of iterative FGNLS estimation when `ifgnls` is specified.

`ifgnlsiterate(#)` specifies the maximum number of FGNLS iterations to perform. The default is the number set using `set maxiter` (see `R` maximize), which is 16,000 by default. To use this option, you must also specify the `ifgnls` option.

`ifgnlseps(#)` specifies the convergence criterion for successive estimates of the error covariance matrix during iterative FGNLS estimation. The default is `ifgnlseps(1e-10)`. To use this option, you must also specify the `ifgnls` option.

`delta(#)` specifies the relative change in a parameter, $\delta$, to be used in computing the numeric derivatives. The derivative for parameter $\beta_i$ is computed as

$$\frac{f_i(x_i, \beta_1, \beta_2, \ldots, \beta_i + d, \beta_{i+1}, \ldots) - f_i(x_i, \beta_1, \beta_2, \ldots, \beta_i, \beta_{i+1}, \ldots)}{d}$$

where $d = \delta(|\beta_i| + \delta)$. The default is `delta(4e-7)`.

`noconstants` indicates that none of the equations in the system includes constant terms. This option is generally not needed, even if there are no constant terms in the system; though in rare cases without this option, `nlsur` may claim that there is one or more constant terms even if there are none.

`hasconstants(namelist)` indicates the parameters that are to be treated as constant terms in the system of equations. The number of elements of `namelist` must equal the number of equations in the system. The $i$th entry of `namelist` specifies the constant term in the $i$th equation. If an equation does not include a constant term, specify a period (.) instead of a parameter name. This option is seldom needed with the interactive and programmed substitutable expression versions, because in those cases `nlsur` can almost always find the constant terms automatically.

The following options are available with `nlsur` but are not shown in the dialog box: `coeflegend`; see `R` estimation options.

**Remarks and examples**

Remarks are presented under the following headings:

- Introduction
- Substitutable expression programs
- Function evaluator programs
Introduction

\texttt{nlsur} fits a system of nonlinear equations by FGNLS. It can be viewed as a nonlinear variant of Zellner’s seemingly unrelated regression model (Zellner 1962; Zellner and Huang 1962; Zellner 1963) and is therefore commonly called nonlinear SUR or nonlinear SURE. The model is also discussed in textbooks such as Davidson and MacKinnon (1993) and Greene (2012, 305–306). Formally, the model fit by \texttt{nlsur} is

\[
y_{i1} = f_1(x_i, \beta) + u_{i1} \\
y_{i2} = f_2(x_i, \beta) + u_{i2} \\
\vdots \\
y_{iM} = f_M(x_i, \beta) + u_{iM}
\]

for \(i = 1, \ldots, N\) observations and \(m = 1, \ldots, M\) equations. The errors for the \(i\)th observation, \(u_{i1}, u_{i2}, \ldots, u_{iM}\), may be correlated, so fitting the \(m\) equations jointly may lead to more efficient estimates. Moreover, fitting the equations jointly allows us to impose cross-equation restrictions on the parameters. Not all elements of the parameter vector \(\beta\) and data vector \(x\), must appear in all the equations, though each element of \(\beta\) must appear in at least one equation for \(\beta\) to be identified. For this model, iterative FGNLS estimation is equivalent to maximum likelihood estimation with multivariate normal disturbances.

The syntax you use with \texttt{nlsur} closely mirrors that used with \texttt{nl}. In particular, you use substitutable expressions with the interactive and programmed substitutable expression versions to define the functions in your system. See [R] \texttt{nl} for more information on substitutable expressions. Here we reiterate the three rules that you must follow:

1. Parameters of the model are bound in braces: \{b0\}, \{param\}, etc.
2. Initial values for parameters are given by including an equal sign and the initial value inside the braces: \{b0=1\}, \{param=3.571\}, etc. If you do not specify an initial value, that parameter is initialized to zero. The initial() option overrides initial values in substitutable expressions.
3. Linear combinations of variables can be included using the notation \{eqname: varlist\}, for example, \{xb: mpg price weight\}, \{score: wxz\}, etc. Parameters of linear combinations are initialized to zero.

Example 1: Interactive version using two-step FGNLS estimator

We have data from an experiment in which two closely related types of bacteria were placed in a Petri dish, and the number of each type of bacteria were recorded every hour. We suspect a two-parameter exponential growth model can be used to model each type of bacteria, but because they shared the same dish, we want to allow for correlation in the error terms. We want to fit the system of equations

\[
p_1 = \beta_1 \beta_2^t + u_1 \\
p_2 = \gamma_1 \gamma_2^t + u_2
\]

where \(p_1\) and \(p_2\) are the two populations and \(t\) is time, and we want to allow for nonzero correlation between \(u_1\) and \(u_2\). We type
. use http://www.stata-press.com/data/r14/petridish
. nlsur (p1 = {b1}*{b2}^t) (p2 = {g1}*{g2}^t)
( obs = 25)

Calculating NLS estimates...

Iteration 1:  Residual SS = 333.8583
Iteration 2:  Residual SS = 219.9233
Iteration 3:  Residual SS = 127.9355
Iteration 4:  Residual SS = 127.9355
Iteration 5:  Residual SS = 127.9355
Iteration 6:  Residual SS = 127.9355
Iteration 7:  Residual SS = 127.9355
Iteration 8:  Residual SS = 127.9355
Iteration 9:  Residual SS = 127.9355

Calculating FGNLS estimates...
Iteration 0:  Scaled RSS = 49.99892
Iteration 1:  Scaled RSS = 49.99892
Iteration 2:  Scaled RSS = 49.99892

FGNLS regression

| Equation | Obs |Parms|RMSE R-sq  Constant |
|----------|-----|-----|------|------------|
| 1        | p1  |25   |2 .4337019 .9734* (none) |
| 2        | p2  |25   |2 .3783479 .9776* (none) |

* Uncentered R-sq

|          | Coef. | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|----------|-------|-----------|------|------|---------------------|
| /b1      | .3926631 | .064203  | 6.12 | 0.000 | .2668275 .5184987   |
| /b2      | 1.119593  | .0088999 | 125.80 | 0.000 | 1.102149 1.137036   |
| /g1      | .5090441  | .0669495 | 7.60 | 0.000 | .3778256 .6402626   |
| /g2      | 1.102315  | .0072183 | 152.71 | 0.000 | 1.088167 1.116463   |

The header of the output contains a summary of each equation, including the number of observations and parameters and the root mean squared error of the residuals. 

The model we fit in the next three examples is in fact linear in the parameters, so it could be fit using the sureg command. However, we will fit the model using nlsur so that we can focus on the mechanics of using the command. Moreover, using nlsur will obviate the need to generate several variables as well as the need to use the constraint command to impose parameter restrictions.

**Example 2: Interactive version using iterative FGNLS estimator—the translog production function**

Greene (1997, sec. 15.6) discusses the transcendental logarithmic (translog) cost function and provides cost and input price data for capital, labor, energy, and materials for the U.S. economy. One way to fit the translog production function to these data is to fit the system of three equations
\[ s_k = \beta_k + \delta_{kk} \ln \left( \frac{p_k}{p_m} \right) + \delta_{kl} \ln \left( \frac{p_l}{p_m} \right) + \delta_{ke} \ln \left( \frac{p_e}{p_m} \right) + u_1 \]

\[ s_l = \beta_l + \delta_{kl} \ln \left( \frac{p_k}{p_m} \right) + \delta_{ll} \ln \left( \frac{p_l}{p_m} \right) + \delta_{le} \ln \left( \frac{p_e}{p_m} \right) + u_2 \]

\[ s_e = \beta_e + \delta_{ke} \ln \left( \frac{p_k}{p_m} \right) + \delta_{le} \ln \left( \frac{p_l}{p_m} \right) + \delta_{ee} \ln \left( \frac{p_e}{p_m} \right) + u_3 \]

where \( s_k \) is capital’s cost share, \( s_l \) is labor’s cost share, and \( s_e \) is energy’s cost share; \( p_k, p_l, p_e, \) and \( p_m \) are the prices of capital, labor, energy, and materials, respectively; the \( u \)’s are regression error terms; and the \( \beta \)’s and \( \delta \)’s are parameters to be estimated. There are three cross-equation restrictions on the parameters: \( \delta_{kl}, \delta_{ke}, \) and \( \delta_{le} \) each appear in two equations. To fit this model by using the iterative FGNLS estimator, we type

```
use http://www.stata-press.com/data/r14/mfgcost
.nlsur (s_k = {bk} + {dkk}*ln(p_k/p_m) + {dkl}*ln(p_l/p_m) + {dke}*ln(p_e/p_m))

We draw your attention to the iteration log at the top of the output. When iterative FGNLS estimation is used, the final scaled RSS will equal the product of the number of observations in the estimation sample and the number of equations; see Methods and formulas for details. Because the RSS is
scaled by the error covariance matrix during each round of FGNLS estimation, the scaled RSS is not comparable from one FGNLS iteration to the next.

Technical note

You may have noticed that we mentioned having data for four factors of production, yet we fit only three share equations. Because the four shares sum to one, we must drop one of the equations to avoid having a singular error covariance matrix. The iterative FGNLS estimator is equivalent to maximum likelihood estimation, and thus it is invariant to which one of the four equations we choose to drop. The (linearly restricted) parameters of the fourth equation can be obtained using the \texttt{lincom} command. Nonlinear functions of the parameters, such as the elasticities of substitution, can be computed using \texttt{nlcom}.

Substitutable expression programs

If you fit the same model repeatedly or you want to share code with colleagues, you can write a substitutable expression program to define your system of equations and avoid having to retype the system every time. The first five letters of the program’s name must be \texttt{nlsur}, and the program must set the r-class macro \texttt{r(n_eq)} to the number of equations in your system. The first equation’s substitutable expression must be returned in \texttt{r(eq_1)}, the second equation’s in \texttt{r(eq_2)}, and so on. You may optionally set \texttt{r(title)} to label your output; that has the same effect as specifying the \texttt{title()} option.

Example 3: Programmed substitutable expression version

We return to our translog cost function, for which a substitutable expression program is

```
program nlsurtranslog, rclass
    version 14.2
    syntax varlist(min=7 max=7) [if]
    tokenize `varlist'
    args sk sl se pk pl pe pm
    local pkpm ln('pk'/'pm')
    local plpm ln('pl'/'pm')
    local pepm ln('pe'/'pm')
    return scalar n_eq = 3
    return local eq_1 = `sk'= {bk} + {dkk}*'pkpm' + {dkl}*'plpm' + {dke}*'pepm'
    return local eq_2 = `sl'= {bl} + {dkl}*'pkpm' + {dll}*'plpm' + {dle}*'pepm'
    return local eq_3 = `se'= {be} + {dke}*'pkpm' + {dle}*'plpm' + {dee}*'pepm'
    return local title = "4-factor translog cost function"
end
```

We made our program accept seven variables, for the three dependent variables $s_k, s_l, s_e,$ and the four factor prices $p_k, p_l, p_m,$ and $p_e$. The \texttt{tokenize} command assigns to macros ‘1’, ‘2’, ..., ‘7’ the seven variables stored in ‘varlist’, and the \texttt{args} command transfers those numbered macros to macros ‘sk’, ‘sl’, ..., ‘pm’. Because we knew our substitutable expressions were going to be somewhat long, we created local macros to hold the log price ratios. These are simply macros that hold strings such as \texttt{ln(pk/pm)}, not variables, and they will save us some repetitious typing when we define our substitutable expressions. Our program returns the number of equations in \texttt{r(n_eq)}, and we defined our substitutable expressions in \texttt{eq_1}, \texttt{eq_2}, and \texttt{eq_3}. We do not bind the expressions in parentheses as we do with the interactive version of \texttt{nlsur}. Finally, we put a title in \texttt{r(title)} to label our output.
Our syntax command also accepts an if clause, and that is how nlsur indicates the estimation sample to our program. In this application, we can safely ignore it, because our program does not compute initial values. However, had we used commands such as summarize or regress to obtain initial values, then we would need to restrict those commands to analyze only the estimation sample. In those cases, typically, you simply need to include ‘if’ with the commands you are using. For example, instead of the command

```
summarize ‘depvar’, meanonly
```
you would use

```
summarize ‘depvar’ ‘if’, meanonly
```

We can check our program by typing

```
.nlsurtranslog s_k s_l s_e pk pl pe pm
.return list
.scalars:
    r(n_eq) = 3
.macros:
    r(title) : "4-factor translog cost function"
    r(eq_3) : "s_e= {be} + {dke}*ln(pk/pm) + {dle}*ln(pl/pm) + {.."
    r(eq_2) : "s_l= {bl} + {dkl}*ln(pk/pm) + {dll}*ln(pl/pm) + {.."
    r(eq_1) : "s_k= {bk} + {dkk}*ln(pk/pm) + {dkl}*ln(pl/pm) + {.."
```

Now that we know that our program works, we fit our model by typing

```
.nlsur translog: s_k s_l s_e pk pl pe pm, ifgnls (obs = 25)

Because we set `r(title)` in our substitutable expression program, the coefficient table has a title attached to it. The estimates are identical to those we obtained in example 2.

### Technical note

`nlsur` accepts frequency and analytic weights as well as `pweights` (sampling weights) and `iweights` (importance weights). You do not need to modify your substitutable expressions in any way to perform weighted estimation, though you must make two changes to your substitutable expression program. The general outline of a `sexp_prog` program is

```stata
program nlsur name, rclass
    version 14.2
    syntax varlist [fw aw pw iw] [if]
    // Obtain initial values incorporating weights. For example,
    summarize varname ['weight''exp' | 'if']
    ...
    // Return n_eqn and substitutable expressions
    return scalar n_eq = #
    return local eq_1 = ...
    ...
end
```

First, we wrote the `syntax` statement to accept a weight expression. Here we allow all four types of weights, but if you know that your estimator is valid, say, for only frequency weights, then you should modify the `syntax` line to accept only `fweights`. Second, if your program computes starting values, then any commands you use must incorporate the weights passed to the program; you do that by including `['weight''exp']` when calling those commands.

### Function evaluator programs

Although substitutable expressions are extremely flexible, there are some problems for which the nonlinear system cannot be defined using them. You can use the function evaluator program version of `nlsur` in these cases. We present two examples, a simple one to illustrate the mechanics of function evaluator programs and a more complicated one to illustrate the power of `nlsur`.

Example 4: Function evaluator program version

Here we write a function evaluator program to fit the translog cost function used in examples 2 and 3. The function evaluator program is

```
program nlsurtranslog2
    version 14.2
    syntax varlist(min=7 max=7) [if], at(name)
    tokenize `varlist'
    args sk sl se pk pl pe pm
    tempname bk dkk dkl dke bl dll dle be dee
    scalar `bk' = `at'[1,1]
    scalar `dkk' = `at'[1,2]
    scalar `dkl' = `at'[1,3]
    scalar `dke' = `at'[1,4]
    scalar `bl' = `at'[1,5]
    scalar `dll' = `at'[1,6]
    scalar `dle' = `at'[1,7]
    scalar `be' = `at'[1,8]
    scalar `dee' = `at'[1,9]
    local pkpm ln(`pk'/'pm')
    local plpm ln(`pl'/'pm')
    local pepm ln(`pe'/'pm')
    quietly {
        replace `sk' = `bk' + `dkk'*`pkpm' + `dkl'*`plpm' + `dke'*`pepm' `if'
        replace `sl' = `bl' + `dkl'*`pkpm' + `dll'*`plpm' + `dle'*`pepm' `if'
        replace `se' = `be' + `dke'*`pkpm' + `dle'*`plpm' + `dee'*`pepm' `if'
    }
end
```

Unlike the substitutable expression program we wrote in example 3, nlsurtranslog2 is not declared as r-class because we will not be returning any stored results. We are again expecting seven variables: three shares and four factor prices, and nlsur will again mark the estimation sample with an if expression.

Our function evaluator program also accepts an option named at(), which will receive a parameter vector at which we are to evaluate the system of equations. All function evaluator programs must accept this option. Our model has nine parameters to estimate, and we created nine temporary scalars to hold the elements of the `at' matrix.

Because our model has three equations, the first three variables passed to our program are the dependent variables that we are to fill in with the function values. We replaced only the observations in our estimation sample by including the `if' qualifier in the replace statements. Here we could have ignored the `if' qualifier because nlsur will skip over observations not in the estimation sample and we did not perform any computations requiring knowledge of the estimation sample. However, including the `if' is good practice and may result in a slight speed improvement if the functions of your model are complicated and the estimation sample is much smaller than the dataset in memory.

We could have avoided creating temporary scalars to hold our individual parameters by writing the replace statements as, for example,

```
replace `sk' = `at'[1,1] + `at'[1,2]*`pkpm' + `at'[1,3]*`plpm' + `at'[1,4]*`pepm' `if'
```

You can use whichever method you find more appealing, though giving the parameters descriptive names reduces the chance for mistakes and makes debugging easier.
To fit our model by using the function evaluator program version of \textit{nlsur}, we type

\begin{verbatim}
  . nlsur translog2 @ s_k s_l s_e pk pl pe pm, ifgnls nequations(3) \\

When we use the function evaluator program version, \texttt{nlsur} requires us to specify the number of equations in \texttt{nequations()}, and it requires us to either specify names for each of our parameters or the number of parameters in the model. Here we used the \texttt{parameters()} option to name our parameters; the order in which we specified them in this option is the same as the order in which we extracted them from the ‘at’ matrix in our program. Had we instead specified \texttt{nparameters(9)}, our parameters would have been labeled \texttt{/b1, /b2, ... /b9} in the output.

\texttt{nlsur} has no way of telling how many parameters appear in each equation, so the \texttt{Parms} column in the header contains missing values. Moreover, the function evaluator program version of \texttt{nlsur} does not attempt to identify constant terms, so we used the \texttt{hasconstant} option to tell \texttt{nlsur} which parameter in each equation is a constant term.

The estimates are identical to those we obtained in examples 2 and 3.

\section*{Technical note}

As with substitutable expression programs, if you intend to do weighted estimation with a function evaluator program, you must modify your \texttt{func_prog} program’s \texttt{syntax} statement to accept weights. Moreover, if you use any statistical commands when computing your nonlinear functions, then you must include the weight expression with those commands.
Example 5: Fitting the basic AIDS model using nlsur

Deaton and Muellbauer (1980) introduce the almost-ideal demand system (AIDS), and Poi (2012) presents a set of commands and several extensions for fitting the AIDS automatically. Here we show how to fit the basic AIDS model, which is a common example of a nonlinear system of equations, by manually using nlsur. The dataset food.dta contains household expenditures, expenditure shares, and log prices for four broad food groups. For a four-good demand system, we need to fit the following system of three equations:

\[
\begin{align*}
    w_1 &= \alpha_1 + \gamma_{11} \ln p_1 + \gamma_{12} \ln p_2 + \gamma_{13} \ln p_3 + \beta_1 \ln \left\{ \frac{m}{P(p)} \right\} + u_1 \\
    w_2 &= \alpha_2 + \gamma_{12} \ln p_1 + \gamma_{22} \ln p_2 + \gamma_{23} \ln p_3 + \beta_2 \ln \left\{ \frac{m}{P(p)} \right\} + u_2 \\
    w_3 &= \alpha_3 + \gamma_{13} \ln p_1 + \gamma_{23} \ln p_2 + \gamma_{33} \ln p_3 + \beta_3 \ln \left\{ \frac{m}{P(p)} \right\} + u_3
\end{align*}
\]

where \( w_k \) denotes a household’s fraction of expenditures on good \( k \), \( \ln p_k \) denotes the logarithm of the price paid for good \( k \), \( m \) denotes a household’s total expenditure on all four goods, the \( u \)’s are regression error terms, and

\[
    \ln P(p) = \alpha_0 + \sum_{i=1}^{4} \alpha_i \ln p_i + \frac{1}{2} \sum_{i=1}^{4} \sum_{j=1}^{4} \gamma_{ij} \ln p_i \ln p_j
\]

The parameters for the fourth good’s share equation can be recovered from the following constraints that are imposed by economic theory:

\[
    \sum_{i=1}^{4} \alpha_i = 1 \quad \sum_{i=1}^{4} \beta_i = 0 \quad \gamma_{ij} = \gamma_{ji} \quad \text{and} \quad \sum_{i=1}^{4} \gamma_{ij} = 0 \text{ for all } j
\]

Our model has a total of 12 unrestricted parameters. We will not estimate \( \alpha_0 \) directly. Instead, we will set it equal to 5; see Deaton and Muellbauer (1980) for a discussion of why treating \( \alpha_0 \) as fixed is acceptable.
Our function evaluator program is

```
program nlsuraids
version 14.2
syntax varlist(min=8 max=8) if, at(name)
tokenize 'varlist'
args w1 w2 w3 lnp1 lnp2 lnp3 lnp4 lnm

end
```

The `syntax` statement accepts eight variables: three expenditure share variables, all four log-price variables, and a variable for log expenditures (\( \ln m \)). Most of the code simply extracts the parameters
from the ‘at’ matrix. Although we are estimating only 12 parameters, to calculate the price index term and the expenditure share equations, we need the restricted parameters as well. Notice how we impose the constraints on the parameters. We then created a temporary variable to hold ln$P(p)$, and we filled the three dependent variables with the predicted expenditure shares.

To fit our model, we type

```
use http://www.stata-press.com/data/r14/food

| (1) | 0.3083643 | 0.0052611 | 58.61 | 0.000 | 0.2980528 - 0.3186758 |
\end{verbatim}

For more information on \texttt{lincom}, see \texttt{[R] lincom}.

### Stored results

\texttt{nlsur} stores the following in \texttt{e()}:

**Scalars**

- \texttt{e(N)}: number of observations
- \texttt{e(k)}: number of parameters
- \texttt{e(k_eq)}: number of parameters for equation \#
- \texttt{e(k_eq_model)}: number of equations in overall model test
- \texttt{e(n_eq)}: number of equations
- \texttt{e(mss_eq)}: model sum of squares for equation \#
- \texttt{e(rss_eq)}: RSS for equation \#
- \texttt{e(rmse_eq)}: root mean squared error for equation \#
- \texttt{e(r2_eq)}: $R^2$ for equation \#
- \texttt{e(ll)}: Gaussian log likelihood (if\texttt{fgls} version only)
- \texttt{e(N_clust)}: number of clusters
- \texttt{e(rank)}: rank of \texttt{e(V)}
- \texttt{e(converge)}: 1 if converged, 0 otherwise

**Macros**

- \texttt{e(cmd)}: \texttt{nlsur}
- \texttt{e(cmdline)}: command as typed
- \texttt{e(method)}: \texttt{fgnls}, \texttt{ifgnls}, or \texttt{nls}
- \texttt{e(depvar)}: names of dependent variables
- \texttt{e(depvar_eq)}: dependent variable for equation \#
- \texttt{e(vtype)}: weight type
- \texttt{e(wexp)}: weight expression
- \texttt{e(title)}: title in estimation output
- \texttt{e(title_2)}: secondary title in estimation output
- \texttt{e(clustvar)}: name of cluster variable
- \texttt{e(vce)}: \texttt{vcetype} specified in \texttt{vce()}
- \texttt{e(vcetype)}: title used in label Std. Err.
- \texttt{e(type)}: 1 = interactively entered expression, 2 = substitutable expression program, 3 = function evaluator program
- \texttt{e(sexpprog)}: substitutable expression program
- \texttt{e(sexp_eq)}: substitutable expression for equation \#
- \texttt{e(params)}: names of all parameters
- \texttt{e(params_eq)}: parameters in equation \#
- \texttt{e(funcprog)}: function evaluator program
- \texttt{e(rhs)}: contents of \texttt{variables()}
- \texttt{e(constants)}: identifies constant terms
- \texttt{e(properties)}: \texttt{b V}
- \texttt{e(predict)}: program used to implement predict
Methods and formulas

Write the system of equations for the $i$th observation as

$$y_i = f(x_i, \beta) + u_i$$

(1)

where $y_i$ and $u_i$ are $1 \times M$ vectors, for $i = 1, \ldots, N$; $f$ is a function that returns a $1 \times M$ vector; $x_i$ represents all the exogenous variables in the system; and $\beta$ is a $1 \times k$ vector of parameters. The generalized nonlinear least-squares system estimator is defined as

$$\hat{\beta} \equiv \arg\min_{\beta} \sum_{i=1}^{N} \{y_i - f(x_i, \beta)\} \Sigma^{-1} \{y_i - f(x_i, \beta)\}'$$

(2)

where $\Sigma = E(u_i' u_i)$ is an $M \times M$ positive-definite weight matrix. Let $T$ be the Cholesky decomposition of $\Sigma^{-1}$; that is, $TT' = \Sigma^{-1}$. Postmultiply (1) by $T$:

$$y_i T = f(x_i, \beta) T + u_i T$$

(3)

Because $E(T'u_i' u_i T) = I$, we can “stack” the columns of (2) and write

$$y_1 T_1 = f(x_1, \beta) T_1 + \tilde{u}_{11}$$

$$y_1 T_2 = f(x_1, \beta) T_2 + \tilde{u}_{12}$$

$$\vdots$$

$$y_1 T_M = f(x_1, \beta) T_M + \tilde{u}_{1M}$$

$$\vdots$$

$$y_N T_1 = f(x_N, \beta) T_1 + \tilde{u}_{N1}$$

$$y_N T_2 = f(x_N, \beta) T_2 + \tilde{u}_{N2}$$

$$\vdots$$

$$y_N T_M = f(x_N, \beta) T_M + \tilde{u}_{NM}$$

(3)

where $T_j$ denotes the $j$th column of $T$. By construction, all $\tilde{u}_{ij}$ are independently distributed with unit variance. As a result, by transforming the model in (1) to that shown in (3), we have reduced the multivariate generalized nonlinear least-squares system estimator to a univariate nonlinear least-squares problem; and the same parameter estimation technique used by \texttt{nl} can be used here. See \texttt{[R] nl} for the details. Moreover, because the $\tilde{u}_{ij}$ all have variance 1, the final scaled RSS reported by \texttt{nlsur} is equal to $NM$. 
To make the estimator feasible, we require an estimate \( \hat{\Sigma} \) of \( \Sigma \). \texttt{nlsur} first sets \( \hat{\Sigma} = I \). Although not efficient, the resulting estimate, \( \hat{\beta}_{NLS} \), is consistent. If the \texttt{nls} option is specified, estimation is complete. Otherwise, the residuals

\[
\hat{u}_i = y_i - f(x_i, \hat{\beta}_{NLS})
\]

are calculated and used to compute

\[
\hat{\Sigma} = \frac{1}{N} \sum_{i=1}^{N} \hat{u}_i' \hat{u}_i
\]

With \( \hat{\Sigma} \) in hand, a new estimate \( \hat{\beta} \) is then obtained.

If the \texttt{ifgnls} option is specified, the new \( \hat{\beta} \) is used to recompute the residuals and obtain a new estimate of \( \hat{\Sigma} \), from which \( \beta \) can then be reestimated. Iterations stop when the relative change in \( \hat{\beta} \) is less than \( \text{eps()} \), the relative change in \( \hat{\Sigma} \) is less than \( \text{ifgnlseps()} \), or if \( \text{ifgnlsiterate()} \) iterations have been performed.

If the \texttt{vce(robust)} and \texttt{vce(cluster clustvar)} options were not specified, then

\[
V(\hat{\beta}) = \left( \sum_{i=1}^{N} X_i' \hat{\Sigma}^{-1} X_i \right)^{-1}
\]

where the \( M \times k \) matrix \( X_i \) has typical element \( X_{ist} \), the derivative of the \( s \)th element of \( f \) with respect to the \( t \)th element of \( \beta \), evaluated at \( x_i \) and \( \hat{\beta} \). As a practical matter, once the model is written in the form of (3), the variance–covariance matrix can be calculated via a Gauss–Newton regression; see Davidson and MacKinnon (1993, chap. 6).

If \texttt{robust} is specified, then

\[
V_R(\hat{\beta}) = \left( \sum_{i=1}^{N} X_i' \hat{\Sigma}^{-1} X_i \right)^{-1} \sum_{i=1}^{N} X_i' \hat{\Sigma}^{-1} \hat{u}_i \hat{u}_i' \hat{\Sigma}^{-1} X_i \left( \sum_{i=1}^{N} X_i' \hat{\Sigma}^{-1} X_i \right)^{-1}
\]

The cluster–robust variance matrix is

\[
V_C(\hat{\beta}) = \left( \sum_{i=1}^{N} X_i' \hat{\Sigma}^{-1} X_i \right)^{-1} \sum_{c=1}^{N_C} w_c' w_c \left( \sum_{i=1}^{N} X_i' \hat{\Sigma}^{-1} X_i \right)^{-1}
\]

where \( N_C \) is the number of clusters and

\[
w_c = \sum_{j \in C_k} X_j' \hat{\Sigma}^{-1} \hat{u}_j'
\]

with \( C_k \) denoting the set of observations in the \( k \)th cluster. In evaluating these formulas, we use the value of \( \hat{\Sigma} \) used in calculating the final estimate of \( \hat{\beta} \). That is, we do not recalculate \( \hat{\Sigma} \) after we obtain the final value of \( \hat{\beta} \).
The RSS for the $j$th equation, $RSS_j$, is

$$RSS_j = \sum_{i=1}^{N} (\hat{y}_{ij} - y_{ij})^2$$

where $\hat{y}_{ij}$ is the predicted value of the $i$th observation on the $j$th dependent variable; the total sum of squares (TSS) for the $j$th equation, $TSS_j$, is

$$TSS_j = \sum_{i=1}^{N} (y_{ij} - \bar{y}_j)^2$$

if there is a constant term in the $j$th equation, where $\bar{y}_j$ is the sample mean of the $j$th dependent variable, and

$$TSS_j = \sum_{i=1}^{N} y_{ij}^2$$

if there is no constant term in the $j$th equation; and the model sum of squares (MSS) for the $j$th equation, $MSS_j$, is $TSS_j - RSS_j$.

The $R^2$ for the $j$th equation is $MSS_j / TSS_j$. If an equation does not have a constant term, then the reported $R^2$ for that equation is “uncentered” and based on the latter definition of $TSS_j$.

Under the assumption that the $u_i$ are independent and identically distributed $N(0, \hat{\Sigma})$, the log likelihood for the model is

$$\ln L = -\frac{MN}{2} \left\{ 1 + \ln(2\pi) \right\} - \frac{N}{2} \ln \left| \hat{\Sigma} \right|$$

The log likelihood is reported only when the `ifgnls` option is specified.

* You must specify the `variables()` option with `nlsur`. 
predict

Description for predict

predict creates a new variable containing predictions such as fitted values and residuals.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, equation(#eqno) yhat residuals]
```

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Options for predict

- `equation(#eqno)` specifies to which equation you are referring. `equation(#1)` would mean that the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. If you do not specify `equation()`, results are the same as if you had specified `equation(#1)

- `yhat`, the default, calculates the fitted values for the specified equation.
- `residuals` calculates the residuals for the specified equation.
margins

Description for margins

margins estimates margins of response for fitted values.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [ options ]

statistic Description

yhat fitted values; the default
residuals not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than \( e(b) \).
For the full syntax, see \([R]\) margins.

Remarks and examples

Example 1

In example 2 of \([R]\) nlsur, we fit a four-factor translog cost function to data for the U.S. economy. The own-price elasticity for a factor measures the percentage change in its usage as a result of a 1% increase in the factor’s price, assuming that output is held constant. For the translog production function, the own-price factor elasticities are

\[
\eta_i = \delta_{ii} + s_i(s_i - 1)
\]

Here we compute the elasticity for capital at the sample mean of capital’s factor share. First, we use summarize to get the mean of \( s_k \) and store that value in a scalar:

\[
\begin{array}{l}
\text{. use http://www.stata-press.com/data/r14/mfgcost} \\
\text{. nlsur (s_k = {bk} + {dkk}*ln(pk/pm) + {dkl}*ln(pl/pm) + {dke}*ln(pe/pm))} \\
\text{> (s_l = {bl} + {dkl}*ln(pk/pm) + {dll}*ln(pl/pm) + {dle}*ln(pe/pm))} \\
\text{> (s_e = {be} + {dke}*ln(pk/pm) + {dle}*ln(pl/pm) + {dee}*ln(pe/pm)),} \\
\text{> ifgnls} \\
\text{(output omitted)} \\
\text{. summarize s_k} \\
\text{Variable | Obs Mean Std. Dev. Min Max} \\
-------------|-------|---------|--------------|---------|---------|
 s_k | 25 | .053488 | .0044795 | .04602 | .06185 |
\end{array}
\]

\[
\text{. scalar kmean = r(mean)}
\]
Now we can use `nlcom` to calculate the elasticity:

```
    . nlcom (([dkk]_cons + kmean*(kmean-1)) / kmean)
     _nl_1: ( [dkk]_cons + kmean*(kmean-1)) / kmean
```

|         | Coef. | Std. Err. | z     | P>|z|   | [95% Conf. Interval] |
|---------|-------|-----------|-------|-------|----------------------|
| _nl_1   | -0.3952986 | 0.1083535 | -3.65 | 0.000 | -0.6076676 -0.1829295 |

If the price of capital increases by 1%, its usage will decrease by about 0.4%. To maintain its current level of output, a firm would increase its usage of other inputs to compensate for the lower capital usage. The standard error reported by `nlcom` reflects the sampling variance of the estimated parameter $\hat{\delta_{kk}}$, but `nlcom` treats the sample mean of $s_k$ as a fixed parameter that does not contribute to the sampling variance of the estimated elasticity.

[R] `nlsur` — Estimation of nonlinear systems of equations
[U] 20 Estimation and postestimation commands
nptrend — Test for trend across ordered groups

Description

nptrend performs a nonparametric test for trend across ordered groups.

Quick start

Nonparametric test for a trend in v1 across ordered categories of catvar
nptrend v1, by(catvar)

As above, but for cases where v2 is greater than 0
nptrend v1 if v2 > 0, by(catvar)

Menu

Statistics > Nonparametric analysis > Tests of hypotheses > Trend test across ordered groups
nptrend — Test for trend across ordered groups

Syntax

\[
\text{nptrend} \ varname \ [\text{if}] \ [\text{in}], \ \text{by(} \ groupvar \ \text{)} \ [\text{nodetail} \ \text{nolabel} \ \text{score} \ (\text{scorevar})]
\]

Options

- **by(\text{groupvar})** is required; it specifies the group on which the data are to be ordered.
- **nodetail** suppresses the listing of group rank sums.
- **nolabel** specifies that \text{group()} values be displayed instead of value labels.
- **score(\text{scorevar})** defines scores for groups. When it is not specified, the values of \text{groupvar} are used for the scores.

Remarks and examples

\text{nptrend} performs the nonparametric test for trend across ordered groups developed by Cuzick (1985), which is an extension of the Wilcoxon rank-sum test (see [R] ranksum). A correction for ties is incorporated into the test. \text{nptrend} is a useful adjunct to the Kruskal–Wallis test; see [R] kwallis.

If your data are not grouped, you can test for trend with the \text{signtest} and \text{spearman} commands; see [R] signrank and [R] spearman. With \text{signtest}, you can perform the Cox and Stuart test, a sign test applied to differences between equally spaced observations of \text{varname}. With \text{spearman}, you can perform the Daniels test, a test of zero Spearman correlation between \text{varname} and a time index. See Conover (1999, 169–175, 323) for a discussion of these tests and their asymptotic relative efficiency.

Example 1

The following data (Altman 1991, 217) show ocular exposure to ultraviolet radiation for 32 pairs of sunglasses classified into three groups according to the amount of visible light transmitted.

<table>
<thead>
<tr>
<th>Group</th>
<th>Transmission of visible light</th>

     (output omitted)
31.    > 35% 8.9
32.    > 35% 13.5
```

We use `nptrend` to test for a trend of (increasing) exposure across the three groups by typing

```stata
.nptrend exposure, by(group)
group    score    obs    sum of ranks
< 25%    1        6      76
25% to 35% 2       18     290
> 35%    3        8      162
z = 1.52 Prob > |z| = 0.129
```

When the groups are given any equally spaced scores (such as $-1$, $0$, $1$), we will obtain the same answer as above. To illustrate the effect of changing scores, an analysis of these data with scores $1$, $2$, and $5$ (admittedly not sensible here) produces

```stata
.generate mysc = cond(group==3,5,group)
.nptrend exposure, by(group) score(mysc)
group    score    obs    sum of ranks
< 25%    1        6      76
25% to 35% 2       18     290
> 35%    5        8      162
z = 1.46 Prob > |z| = 0.143
```

This example suggests that the analysis is not all that sensitive to the scores chosen.

---

**Technical note**

The grouping variable may be either a string variable or a numeric variable. If it is a string variable and no score variable is specified, the natural numbers $1$, $2$, $3$, ... are assigned to the groups in the sort order of the string variable. This may not always be what you expect. For example, the sort order of the strings “one”, “two”, “three” is “one”, “three”, “two”.

---
Stored results

nptrend stores the following in r():

<table>
<thead>
<tr>
<th>Scalars</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>r(N)</td>
<td>number of observations</td>
</tr>
<tr>
<td>r(z)</td>
<td>z statistic</td>
</tr>
<tr>
<td>r(p)</td>
<td>two-sided p-value</td>
</tr>
<tr>
<td>r(T)</td>
<td>test statistic</td>
</tr>
</tbody>
</table>

Methods and formulas

nptrend is based on a method in Cuzick (1985). The following description of the statistic is from Altman (1991, 215–217). We have \( k \) groups of sample sizes \( n_i (i = 1, \ldots, k) \). The groups are given scores, \( l_i \), which reflect their ordering, such as 1, 2, and 3. The scores do not have to be equally spaced, but they usually are. \( N = \sum n_i \) observations are ranked from 1 to \( N \), and the sums of the ranks in each group, \( R_i \), are obtained. \( L \), the weighted sum of all the group scores, is

\[
L = \sum_{i=1}^{k} l_i n_i
\]

The statistic \( T \) is calculated as

\[
T = \sum_{i=1}^{k} l_i R_i
\]

Under the null hypothesis, the expected value of \( T \) is \( E(T) = 0.5(N+1)L \), and its standard error is

\[
se(T) = \sqrt{\frac{N+1}{12} \left( N \sum_{i=1}^{k} l_i^2 n_i - L^2 \right)}
\]

so that the test statistic, \( z \), is given by

\[
z = \frac{T - E(T)}{se(T)}
\]

which has an approximately standard normal distribution when the null hypothesis of no trend is true.

The correction for ties affects the standard error of \( T \). Let \( \tilde{N} \) be the number of unique values of the variable being tested (\( \tilde{N} \leq N \)), and let \( t_j \) be the number of times the \( j \)th unique value of the variable appears in the data. Define

\[
a = \frac{\sum_{j=1}^{\tilde{N}} t_j (t_j^2 - 1)}{N(N^2 - 1)}
\]

The corrected standard error of \( T \) is

\[
\tilde{se}(T) = \sqrt{1 - a} \ se(T).
\]

**ologit — Ordered logistic regression**

**Description**

`ologit` fits ordered logit models of ordinal variable `depvar` on the independent variables `indepvars`. The actual values taken on by the dependent variable are irrelevant, except that larger values are assumed to correspond to “higher” outcomes.

**Quick start**

Ordinal logit model of `y` on `x1` and categorical variables `a` and `b`

```
ologit y x1 i.a i.b
```

As above, and include interaction between `a` and `b` and report results as odds ratios

```
ologit y x1 a##b, or
```

With bootstrap standard errors

```
ologit y x1 i.a i.b, vce(bootstrap)
```

Analysis restricted to cases where `catvar = 0` using `svyset` data with replicate weights

```
svy bootstrap, subpop(if catvar==0): ologit y x1 i.a i.b
```

**Menu**

Statistics > Ordinal outcomes > Ordered logistic regression
## Syntax

```
ologit depvar [ indepvars ] [ if ] [ in ] [ weight ] [ , options ]
```

### options Description

**Model**
- `offset(varname)` include `varname` in model with coefficient constrained to 1
- `constraints(constraints)` apply specified linear constraints
- `collinear` keep collinear variables

**SE/Robust**
- `vce(vcetype)` `vcetype` may be `oim`, `robust`, `cluster clustvar`, `bootstrap`, or `jackknife`

**Reporting**
- `level(#)` set confidence level; default is `level(95)`
- `nocnsreport` do not display constraints
- `display_options` control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

**Maximization**
- `maximize_options` control the maximization process; seldom used
- `coeflegend` display legend instead of statistics

*Arguments*:
- `indepvars` may contain factor variables; see [U] 11.4.3 Factor variables.
- `depvar` and `indepvars` may contain time-series operators; see [U] 11.4.4 Time-series varlists.
- `bootstrap`, `by`, `fp`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 Prefix commands.
- `vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] mi estimate.
- `vce()` and weights are not allowed with the `svy` prefix; see [SVY] svy.
- `fweight`, `iweight`, and `pweight` are allowed; see [U] 11.1.6 weight.
- `coeflegend` does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model
- `offset(varname)`, `constraints(constraints)`, `collinear`; see [R] estimation options.

### SE/Robust
- `vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] vce_option.
or reports the estimated coefficients transformed to odds ratios, that is, $e^b$ rather than $b$. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. or may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R estimation options].

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwwrap(#)`, `fwwrapon(style)`, `cformat(%%fmt)`, `pformat(%%fmt)`, `sformat(%%fmt)`, and `nolstretch`; see [R estimation options].

**Remarks and examples**

Ordered logit models are used to estimate relationships between an ordinal dependent variable and a set of independent variables. An ordinal variable is a variable that is categorical and ordered, for instance, “poor”, “good”, and “excellent”, which might indicate a person’s current health status or the repair record of a car. If there are only two outcomes, see [R logistic, R logit, and R probit. This entry is concerned only with models in which the outcomes can be ordered. In ordered logit, an underlying score is estimated as a linear function of the independent variables and a set of cutpoints. The probability of observing outcome $i$ corresponds to the probability that the estimated linear function, plus random error, is within the range of the cutpoints estimated for the outcome:

$$\Pr(\text{outcome}_j = i) = \Pr(\kappa_{i-1} < \beta_1 x_{1j} + \beta_2 x_{2j} + \cdots + \beta_k x_{kj} + u_j \leq \kappa_i)$$

$u_j$ is assumed to be logistically distributed in ordered logit. In either case, we estimate the coefficients $\beta_1$, $\beta_2$, $\ldots$, $\beta_k$ together with the cutpoints $\kappa_1$, $\kappa_2$, $\ldots$, $\kappa_{k-1}$, where $k$ is the number of possible outcomes. $\kappa_0$ is taken as $-\infty$, and $\kappa_k$ is taken as $+\infty$. All of this is a direct generalization of the ordinary two-outcome logit model.

**Example 1**

We wish to analyze the 1977 repair records of 66 foreign and domestic cars. The data are a variation of the automobile dataset described in [U 1.2.2 Example datasets. The 1977 repair records, like those in 1978, take on values “Poor”, “Fair”, “Average”, “Good”, and “Excellent”. Here is a cross-tabulation of the data:
. use http://www.stata-press.com/data/r14/fullauto
(Automobile Models)
. tabulate rep77 foreign, chi2

<table>

</tbody>
</table>

Pearson chi2(4) = 13.8619 Pr = 0.008

Although it appears that foreign takes on the values Domestic and Foreign, it is actually a numeric variable taking on the values 0 and 1. Similarly, rep77 takes on the values 1, 2, 3, 4, and 5, corresponding to Poor, Fair, and so on. The more meaningful words appear because we have attached value labels to the data; see [U] 12.6.3 Value labels.

Because the chi-squared value is significant, we could claim that there is a relationship between foreign and rep77. Literally, however, we can only claim that the distributions are different; the chi-squared test is not directional. One way to model these data is to model the categorization that took place when the data were created. Cars have a true frequency of repair, which we will assume is given by \( S_j = \beta \text{foreign}_j + u_j \), and a car is categorized as “poor” if \( S_j \leq \kappa_0 \), as “fair” if \( \kappa_0 < S_j \leq \kappa_1 \), and so on:

. ologit rep77 foreign

| Iteration 0: log likelihood = -89.895098 |
| Iteration 1: log likelihood = -85.951765 |
| Iteration 2: log likelihood = -85.908227 |
| Iteration 3: log likelihood = -85.908161 |
| Iteration 4: log likelihood = -85.908161 |

Ordered logistic regression

| rep77 | Coef. | Std. Err. | z    | P>|z|   | [95% Conf. Interval] |
|-------|-------|-----------|------|--------|---------------------|
| foreign | 1.455878 | .5308951 | 2.74 | 0.006 | .4153425 2.496413 |
| /cut1 | -2.765562 | .5988208 | -2.77 | 0.006 | -3.939229 -1.591895 |
| /cut2 | -.9963603 | .3217706 | -3.14 | 0.002 | -1.627019 -.3657016 |
| /cut3 | .9426153 | .3136398 | 2.99 | 0.003 | .3278925 1.557338 |
| /cut4 | 3.123351 | .5423257 | 5.77 | 0.000 | 2.060412 4.18629 |

Our model is \( S_j = 1.46 \text{foreign}_j + u_j \); the expected value for foreign cars is 1.46 and, for domestic cars, 0; foreign cars have better repair records.

The estimated cutpoints tell us how to interpret the score. For a foreign car, the probability of a poor record is the probability that \( 1.46 + u_j \leq -2.77 \), or equivalently, \( u_j \leq -4.23 \). Making this calculation requires familiarity with the logistic distribution: the probability is \( 1/(1 + e^{4.23}) = 0.014 \). On the other hand, for domestic cars, the probability of a poor record is the probability \( u_j \leq -2.77 \), which is 0.059.
This, it seems to us, is a far more reasonable prediction than we would have made based on the table alone. The table showed that 2 of 45 domestic cars had poor records, whereas 1 of 21 foreign cars had poor records—corresponding to probabilities $\frac{2}{45} = 0.044$ and $\frac{1}{21} = 0.048$. The predictions from our model imposed a smoothness assumption—foreign cars should not, overall, have better repair records without the difference revealing itself in each category. In our data, the fractions of foreign and domestic cars in the poor category are virtually identical only because of the randomness associated with small samples.

Thus if we were asked to predict the true fractions of foreign and domestic cars that would be classified in the various categories, we would choose the numbers implied by the ordered logit model:

<table>
<thead>
<tr>
<th></th>
<th>Domestic</th>
<th>Foreign</th>
<th></th>
<th>Domestic</th>
<th>Foreign</th>
</tr>
</thead>
<tbody>
<tr>
<td>Poor</td>
<td>0.044</td>

<td>0.333</td>
<td></td>
<td>0.238</td>
<td>0.467</td>
</tr>
<tr>
<td>Excellent</td>
<td>0.000</td>
<td>0.238</td>
<td></td>
<td>0.043</td>
<td>0.159</td>
</tr>
</tbody>
</table>

See [R] ologit postestimation for a more complete explanation of how to generate predictions from an ordered logit model.

Technical note

Here ordered logit provides an alternative to ordinary two-outcome logistic models with an arbitrary dichotomization, which might otherwise have been tempting. We could, for instance, have summarized these data by converting the five-outcome rep77 variable to a two-outcome variable, combining cars in the average, fair, and poor categories to make one outcome and combining cars in the good and excellent categories to make the second.

Another even less appealing alternative would have been to use ordinary regression, arbitrarily labeling “excellent” as 5, “good” as 4, and so on. The problem is that with different but equally valid labelings (say, 10 for “excellent”), we would obtain different estimates. We would have no way of choosing one metric over another. That assertion is not, however, true of ologit. The actual values used to label the categories make no difference other than through the order they imply.

In fact, our labeling was 5 for “excellent”, 4 for “good”, and so on. The words “excellent” and “good” appear in our output because we attached a value label to the variables; see [U] 12.6.3 Value labels. If we were to now go back and type `replace rep77=10 if rep77==5`, changing all the 5s to 10s, we would still obtain the same results when we refit our model.

Example 2

In the example above, we used ordered logit as a way to model a table. We are not, however, limited to including only one explanatory variable or to including only categorical variables. We can explore the relationship of rep77 with any of the variables in our data. We might, for instance, model rep77 not only in terms of the origin of manufacture, but also including length (a proxy for size) and mpg:
foreign still plays a role—and an even larger role than previously. We find that larger cars tend to have better repair records, as do cars with better mileage ratings.
**ologit — Ordered logistic regression**

**Stored results**

`ologit` stores the following in `e()`:

### Scalars
- `e(N)` number of observations
- `e(N_cd)` number of completely determined observations
- `e(k_cat)` number of categories
- `e(k)` number of parameters
- `e(k_aux)` number of auxiliary parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(r2_p)` pseudo-$R$-squared
- `e(ll)` log likelihood
- `e(ll_0)` log likelihood, constant-only model
- `e(N_clust)` number of clusters
- `e(chi2)` $\chi^2$
- `e(p)` significance of model test
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise

### Macros
- `e(cmd)` `ologit`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(offset)` linear offset variable
- `e(chi2type)` Wald or LR; type of model $\chi^2$ test
- `e(vcetype)` `vce()` specified in `vce()`
- `e(vcetypex)` title used to label Std. Err.
- `e(opt)` type of optimization
- `e(which)` `max` or `min`; whether optimizer is to perform maximization or minimization
- `e(ml_method)` type of ml method
- `e(user)` name of likelihood-evaluator program
- `e(technique)` maximization technique
- `e(properties)` `b V`
- `e(predict)` program used to implement `predict`
- `e(marginsdefault)` default `predict()` specification for `margins`
- `e(asbalanced)` factor variables `fvset` as `asbalanced`
- `e(asobserved)` factor variables `fvset` as `asobserved`

### Matrices
- `e(b)` coefficient vector
- `e(Cns)` constraints matrix
- `e(ilog)` iteration log (up to 20 iterations)
- `e(gradient)` gradient vector
- `e(cat)` category values
- `e(V)` variance–covariance matrix of the estimators
- `e(V_modelbased)` model-based variance

### Functions
- `e(sample)` marks estimation sample
Methods and formulas

See Long and Freese (2014, chap. 7) for a discussion of models for ordinal outcomes and examples that use Stata. Cameron and Trivedi (2005, chap. 15) describe multinomial models, including the model fit by ologit. When you have a qualitative dependent variable, several estimation procedures are available. A popular choice is multinomial logistic regression (see \[R\] mlogit), but if you use this procedure when the response variable is ordinal, you are discarding information because multinomial logit ignores the ordered aspect of the outcome. Ordered logit and probit models provide a means to exploit the ordering information.

There is more than one “ordered logit” model. The model fit by ologit, which we will call the ordered logit model, is also known as the proportional odds model. Another popular choice, not fit by ologit, is known as the stereotype model; see \[R\] slogit. All ordered logit models have been derived by starting with a binary logit/probit model and generalizing it to allow for more than two outcomes.

The proportional-odds ordered logit model is so called because, if we consider the odds \( \text{odds}(k) = P(Y \leq k)/P(Y > k) \), then \( \text{odds}(k_1) \) and \( \text{odds}(k_2) \) have the same ratio for all independent variable combinations. The model is based on the principle that the only effect of combining adjoining categories in ordered categorical regression problems should be a loss of efficiency in estimating the regression parameters (McCullagh 1980). This model was also described by McKelvey and Zavoina (1975) and, previously, by Aitchison and Silvey (1957) in a different algebraic form. Brant (1990) offers a set of diagnostics for the model.

Peterson and Harrell (1990) suggest a model that allows nonproportional odds for a subset of the explanatory variables. ologit does not allow this, but a model similar to this was implemented by Fu (1998).

The stereotype model rejects the principle on which the ordered logit model is based. Anderson (1984) argues that there are two distinct types of ordered categorical variables: “grouped continuous”, such as income, where the “type a” model applies; and “assessed”, such as extent of pain relief, where the stereotype model applies. Greenland (1985) independently developed the same model. The stereotype model starts with a multinomial logistic regression model and imposes constraints on this model.

Goodness of fit for ologit can be evaluated by comparing the likelihood value with that obtained by fitting the model with mlogit. Let \( \ln L_1 \) be the log-likelihood value reported by ologit, and let \( \ln L_0 \) be the log-likelihood value reported by mlogit. If there are \( p \) independent variables (excluding the constant) and \( k \) categories, mlogit will estimate \( p(k-1) \) additional parameters. We can then perform a “likelihood-ratio test”, that is, calculate \(-2(\ln L_1 - \ln L_0)\), and compare it with \( \chi^2\{p(k-2)\} \). This test is suggestive only because the ordered logit model is not nested within the multinomial logit model. A large value of \(-2(\ln L_1 - \ln L_0)\) should, however, be taken as evidence of poorness of fit. Marginally large values, on the other hand, should not be taken too seriously.

The coefficients and cutpoints are estimated using maximum likelihood as described in \[R\] maximize. In our parameterization, no constant appears, because the effect is absorbed into the cutpoints.

ologit and oprobit begin by tabulating the dependent variable. Category \( i = 1 \) is defined as the minimum value of the variable, \( i = 2 \) as the next ordered value, and so on, for the empirically determined \( k \) categories.
The probability of a given observation for ordered logit is

\[ p_{ij} = \Pr(y_j = i) = \Pr(\kappa_{i-1} < x_j \beta + u \leq \kappa_i) \]

\[ = \frac{1}{1 + \exp(-\kappa_i + x_j \beta)} - \frac{1}{1 + \exp(-\kappa_i - x_j \beta)} \]

\( \kappa_0 \) is defined as \(-\infty\) and \( \kappa_k \) as \( +\infty \).

For ordered probit, the probability of a given observation is

\[ p_{ij} = \Pr(y_j = i) = \Pr(\kappa_{i-1} < x_j \beta + u \leq \kappa_i) \]

\[ = \Phi(\kappa_i - x_j \beta) - \Phi(\kappa_i - x_j \beta) \]

where \( \Phi(\cdot) \) is the standard normal cumulative distribution function.

The log likelihood is

\[ \ln L = \sum_{j=1}^{N} w_j \sum_{i=1}^{k} I_i(y_j) \ln p_{ij} \]

where \( w_j \) is an optional weight and

\[ I_i(y_j) = \begin{cases} 1, & \text{if } y_j = i \\ 0, & \text{otherwise} \end{cases} \]

ologit and oprobit support the Huber/White/sandwich estimator of the variance and its clustered version using \code{vce(robust)} and \code{vce(cluster clustvar)}, respectively. See \cite{robust}, particularly \code{Maximum likelihood estimators} and \code{Methods and formulas}.

These commands also support estimation with survey data. For details on VCEs with survey data, see \cite{SVY} \code{variance estimation}.

<td>predicted probabilities; the default</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the linear prediction</td>
</tr>
</tbody>
</table>

If you do not specify outcome(), pr (with one new variable specified) assumes outcome(#1).
You specify one or k new variables with pr, where k is the number of outcomes.
You specify one new variable with xb and stdp.
These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

pr, the default, calculates the predicted probabilities. If you do not also specify the outcome() option, you specify k new variables, where k is the number of categories of the dependent variable. Say that you fit a model by typing ologit result x1 x2, and result takes on three values. Then you could type predict p1 p2 p3 to obtain all three predicted probabilities. If you specify the outcome() option, you must specify one new variable. Say that result takes on the values 1, 2, and 3. Typing predict p1, outcome(1) would produce the same p1.

xb calculates the linear prediction. You specify one new variable, for example, predict linear, xb. The linear prediction is defined, ignoring the contribution of the estimated cutpoints.

stdp calculates the standard error of the linear prediction. You specify one new variable, for example, predict se, stdp.
outcome(outcome) specifies for which outcome the predicted probabilities are to be calculated. outcome() should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc.

nooffset is relevant only if you specified offset(varname) for ologit. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as x_j b rather than as x_j b + offset_j.

scores calculates equation-level score variables. The number of score variables created will equal the number of outcomes in the model. If the number of outcomes in the model was k, then

the first new variable will contain ∂ln L/∂(x_j b);
the second new variable will contain ∂ln L/∂κ_1;
the third new variable will contain ∂ln L/∂κ_2;
...
and the kth new variable will contain ∂ln L/∂κ_{k-1}, where κ_i refers to the ith cutpoint.

margins

Description for margins

margins estimates margins of response for probabilities and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [ , options ]
margins [marginlist], predict(statistic ...) [ predict(statistic ...) ... ] [ options ]

Statistic Description

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>probabilities for each outcome</td>
</tr>
<tr>
<td>pr</td>

<td>not allowed with margins</td>
</tr>
</tbody>
</table>

pr defaults to the first outcome.

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.
Remarks and examples

See [U] 20 Estimation and postestimation commands for instructions on obtaining the variance–covariance matrix of the estimators, predicted values, and hypothesis tests. Also see [R] lrtest for performing likelihood-ratio tests.

Example 1

In example 2 of [R] ologit, we fit the model ologit rep77 foreign length mpg. The predict command can be used to obtain the predicted probabilities.

We type predict followed by the names of the new variables to hold the predicted probabilities, ordering the names from low to high. In our data, the lowest outcome is “poor”, and the highest is “excellent”. We have five categories, so we must type five names following predict; the choice of names is up to us:

```
. use http://www.stata-press.com/data/r14/fullauto
(Automobile Models)
. ologit rep77 foreign length mpg
(output omitted)
. predict poor fair avg good exc
(option pr assumed; predicted probabilities)
. list exc good make model rep78 if rep77>=., sep(4) divider
```

<table>

<td>.</td>
</tr>
</tbody>
</table>

The eight cars listed were introduced after 1977, so they do not have 1977 repair records in our data. We predicted what their 1977 repair records might have been using the fitted model. We see that, based on its characteristics, the Peugeot 604 had about a 41.65 + 6.53 \approx 48.2\% chance of a good or excellent repair record. The Ford Fiesta, which had only a 3\% chance of a good or excellent repair record, in fact, had a good record when it was introduced in the following year.

Technical note

For ordered logit, predict, xb produces \( S_j = x_{1j} \beta_1 + x_{2j} \beta_2 + \cdots + x_{kj} \beta_k \). The ordered-logit predictions are then the probability that \( S_j + u_j \) lies between a pair of cutpoints, \( \kappa_{i-1} \) and \( \kappa_i \). Some handy formulas are

\[
\Pr(S_j + u_j < \kappa) = \frac{1}{1 + e^{S_j - \kappa}} \\
\Pr(S_j + u_j > \kappa) = 1 - \frac{1}{1 + e^{S_j - \kappa}} \\
\Pr(\kappa_1 < S_j + u_j < \kappa_2) = \frac{1}{1 + e^{S_j - \kappa_2}} - \frac{1}{1 + e^{S_j - \kappa_1}}
\]
Rather than using `predict` directly, we could calculate the predicted probabilities by hand. If we wished to obtain the predicted probability that the repair record is excellent and the probability that it is good, we look back at `ologit`’s output to obtain the cutpoints. We find that “good” corresponds to the interval $/cut3 < S_j + u < /cut4$ and “excellent” to the interval $S_j + u > /cut4$:

```
. predict score, xb
. generate probgood = 1/(1+exp(score-_b[/cut4])) - 1/(1+exp(score-_b[/cut3]))
. generate probexc = 1 - 1/(1+exp(score-_b[/cut4]))
```

The results of our calculation will be the same as those produced in the previous example. We refer to the estimated cutpoints just as we would any coefficient, so `_b[/cut3]` refers to the value of the `/cut3` coefficient; see [U] 13.5 Accessing coefficients and standard errors.

[R] `ologit` — Ordered logistic regression

[U] 20 Estimation and postestimation commands
Description

The `oneway` command reports one-way analysis-of-variance (ANOVA) models and performs multiple-comparison tests.

If you wish to fit more complicated ANOVA layouts or wish to fit analysis-of-covariance (ANCOVA) models, see [R] anova.

See [D] encode for examples of fitting ANOVA models on string variables.

See [R] loneway for an alternative oneway command with slightly different features.

Quick start

One-way ANOVA model of $y$ for factor $a$

```
oneway y a
```

Report the mean and std. dev. of $y$ and number of observations for each level of $a$

```
oneway y a, tabulate
```

Report all pairwise comparisons of the means of $y$ across levels of $a$ with $p$-values adjusted using Bonferroni’s procedure

```
oneway y a, bonferroni
```

As above, but adjust $p$-values for multiple comparisons using Scheffé’s method

```
oneway y a, scheffe
```

by is allowed; see [D] by.
aweights and fweights are allowed; see [U] 11.1.6 weight.

Options

```
bonferroni reports the results of a Bonferroni multiple-comparison test.
scheffe reports the results of a Scheffé multiple-comparison test.
sidak reports the results of a Šidák multiple-comparison test.
tabulate produces a table of summary statistics of the response_var by levels of the factor_var. The table includes the mean, standard deviation, frequency, and, if the data are weighted, the number of observations. Individual elements of the table may be included or suppressed by using the [no]means, [no]standard, [no]freq, and [no]obs options. For example, typing

```
oneway response factor, tabulate means standard
```

produces a summary table that contains only the means and standard deviations. You could achieve the same result by typing

```
oneway response factor, tabulate nofreq
```

[no]means includes or suppresses only the means from the table produced by the tabulate option. See tabulate above.

[no]standard includes or suppresses only the standard deviations from the table produced by the tabulate option. See tabulate above.

[no]freq includes or suppresses only the frequencies from the table produced by the tabulate option. See tabulate above.

[no]obs includes or suppresses only the reported number of observations from the table produced by the tabulate option. If the data are not weighted, only the frequency is reported. If the data are weighted, the frequency refers to the sum of the weights. See tabulate above.
noanova suppresses the display of the ANOVA table.
nolabel causes the numeric codes to be displayed rather than the value labels in the ANOVA and multiple-comparison test tables.
wrap requests that Stata not break up wide tables to make them more readable.
missing requests that missing values of factor_var be treated as a category rather than as observations to be omitted from the analysis.

Remarks and examples

Remarks are presented under the following headings:

- Introduction
- Obtaining observed means
- Multiple-comparison tests
- Weighted data
- Video example

Introduction

The oneway command reports one-way ANOVA models. To perform a one-way layout of a variable called endog on exog, type oneway endog exog.

Example 1

We run an experiment varying the amount of fertilizer used in growing apple trees. We test four concentrations, using each concentration in three groves of 12 trees each. Later in the year, we measure the average weight of the fruit.

If all had gone well, we would have had 3 observations on the average weight for each of the four concentrations. Instead, two of the groves were mistakenly leveled by a confused man on a large bulldozer. We are left with the following dataset:

```
. use http://www.stata-press.com/data/r14/apple
(Apple trees)
. describe
Contains data from http://www.stata-press.com/data/r14/apple.dta
obs: 10 Apple trees
vars: 2 16 Jan 2014 11:23
size: 100

storage  display value
variable name type format label variable label

  treatment int  %8.0g Fertilizer
  weight    double %10.0g Average weight in grams
```

Sorted by:
To obtain the one-way ANOVA results, we type

```
. oneway weight treatment
```

<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>F</th>
<th>Prob &gt; F</th>
</tr>
</thead>
<tbody>
<tr>
<td>Between groups</td>
<td>5295.54433</td>
<td>3</td>
<td>1765.18144</td>
<td>21.46</td>
<td>0.0013</td>
</tr>
<tr>
<td>Within groups</td>
<td>493.591667</td>
<td>6</td>
<td>82.2652778</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>5789.136</td>
<td>9</td>
<td>643.237333</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bartlett's test for equal variances: chi2(3) = 1.3900 Prob>chi2 = 0.708

We find significant (at better than the 1% level) differences among the four concentrations.

Technical note

Rather than using the `oneway` command, we could have performed this analysis by using `anova`. Example 1 in [R] `anova` repeats this same analysis. You may wish to compare the output.

You will find the `oneway` command quicker than the `anova` command, and, as you will learn, `oneway` allows you to perform multiple-comparison tests. On the other hand, `anova` will let you generate predictions, examine the covariance matrix of the estimators, and perform more general hypothesis tests.

Technical note

Although the output is a usual ANOVA table, let’s run through it anyway. The between-group sum of squares for the model is 5295.5 with 3 degrees of freedom, resulting in a mean square of $\frac{5295.5}{3} \approx 1765.2$. The corresponding $F$ statistic is 21.46 and has a significance level of 0.0013. Thus the model appears to be significant at the 0.13% level.

The second line summarizes the within-group (residual) variation. The within-group sum of squares is 493.59 with 6 degrees of freedom, resulting in a mean squared error of 82.27.

The between- and residual-group variations sum to the total sum of squares (TSS), which is reported as 5789.1 in the last line of the table. This is the TSS of `weight` after removal of the mean. Similarly, the between plus residual degrees of freedom sum to the total degrees of freedom, 9. Remember that there are 10 observations. Subtracting 1 for the mean, we are left with 9 total degrees of freedom.
At the bottom of the table, Bartlett’s test for equal variances is reported. The value of the statistic is 1.39. The corresponding significance level ($\chi^2$ with 3 degrees of freedom) is 0.708, so we cannot reject the assumption that the variances are homogeneous.

### Obtaining observed means

#### Example 2

We typed `oneway weight treatment` to obtain an ANOVA table of weight of fruit by fertilizer concentration. Although we obtained the table, we obtained no information on which fertilizer seems to work the best. If we add the `tabulate` option, we obtain that additional information:

```
. oneway weight treatment, tabulate
```

<table>
<thead>
<tr>
<th>Fertilizer</th>
<th>Summary of Average weight in grams</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Mean</td>
</tr>
<tr>
<td>1</td>

<td>3</td>
<td>1765.18144</td>
<td>21.46</td>
<td>0.0013</td>
</tr>
<tr>
<td>Within</td>
<td>493.591667</td>
<td>6</td>
<td>82.2652778</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>5789.136</td>
<td>9</td>
<td>643.237333</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bartlett’s test for equal variances: $\chi^2(3) = 1.3900$ Prob > $\chi^2 = 0.708$

We find that the average weight was largest when we used fertilizer concentration 1.

### Multiple-comparison tests

#### Example 3: Bonferroni multiple-comparison test

`oneway` can also perform multiple-comparison tests using either Bonferroni, Scheffé, or Šidák normalizations. For instance, to obtain the Bonferroni multiple-comparison test, we specify the `bonferroni` option:
. oneway weight treatment, bonferroni

<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>F</th>
<th>Prob &gt; F</th>
</tr>
</thead>
<tbody>
<tr>
<td>Between groups</td>
<td>5295.54433</td>
<td>3</td>
<td>1765.18144</td>
<td>21.46</td>
<td>0.0013</td>
</tr>
<tr>
<td>Within groups</td>
<td>493.591667</td>
<td>6</td>
<td>82.2652778</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>5789.136</td>
<td>9</td>
<td>643.237333</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bartlett’s test for equal variances: chi2(3) = 1.3900 Prob>chi2 = 0.708

Comparison of Average weight in grams by Fertilizer (Bonferroni)

<table>
<thead>
<tr>
<th>Row Mean - Col Mean</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>-59.1667</td>
<td>0.001</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>-33.25</td>
<td>25.9167</td>
<td>0.042</td>
</tr>
<tr>
<td>4</td>
<td>-34.4</td>
<td>24.7667</td>
<td>-1.15</td>
</tr>
</tbody>
</table>

The results of the Bonferroni test are presented as a matrix. The first entry, −59.17, represents the difference between fertilizer concentrations 2 and 1 (labeled “Row Mean - Col Mean” in the upper stub of the table). Remember that in the previous example we requested the tabulate option. Looking back, we find that the means of concentrations 1 and 2 are 111.90 and 52.73, respectively. Thus $52.73 - 111.90 = -59.17$.

Underneath that number is reported “0.001”. This is the Bonferroni-adjusted significance of the difference. The difference is significant at the 0.1% level. Looking down the column, we see that concentration 3 is also worse than concentration 1 (4.2% level), as is concentration 4 (3.6% level).

On the basis of this evidence, we would use concentration 1 if we grew apple trees.

Example 4: Scheffé multiple-comparison test

We can just as easily obtain the Scheffé-adjusted significance levels. Rather than specifying the bonferroni option, we specify the scheffe option.
We will also add the `noanova` option to prevent Stata from redisplaying the ANOVA table:

```
.oneway weight treatment, noanova scheffe
```

Comparison of Average weight in grams by Fertilizer
(Scheffé)

<p>| Row Mean- | 1     | 2     | 3     |</p>
<table>
<thead>
<tr>
<th>Col Mean</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>-59.1667</td>
<td>0.001</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>-33.25</td>
<td>25.9167</td>
<td>0.039</td>
</tr>
<tr>
<td>4</td>
<td>-34.4</td>
<td>24.7667</td>
<td>-1.15</td>
</tr>
</tbody>
</table>

The differences are the same as those we obtained in the Bonferroni output, but the significance levels are not. According to the Bonferroni-adjusted numbers, the significance of the difference between fertilizer concentrations 1 and 3 is 4.2%. The Scheffé-adjusted significance level is 3.9%.

We will leave it to you to decide which results are more accurate.

---

**Example 5: Šidák multiple-comparison test**

Let's conclude this example by obtaining the Šidák-adjusted multiple-comparison tests. We do this to illustrate Stata’s capabilities to calculate these results, because searching across adjustment methods until you find the results you want is not a valid technique for obtaining significance levels.

```
.oneway weight treatment, noanova sidak
```

Comparison of Average weight in grams by Fertilizer
(Sidak)

<p>| Row Mean- | 1     | 2     | 3     |</p>
<table>
<thead>
<tr>
<th>Col Mean</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>-59.1667</td>
<td>0.001</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>-33.25</td>
<td>25.9167</td>
<td>0.041</td>
</tr>
<tr>
<td>4</td>
<td>-34.4</td>
<td>24.7667</td>
<td>-1.15</td>
</tr>
</tbody>
</table>

We find results that are similar to the Bonferroni-adjusted numbers.

---

Henry Scheffé (1907–1977) was born in New York. He studied mathematics at the University of Wisconsin, gaining a doctorate with a dissertation on differential equations. He taught mathematics at Wisconsin, Oregon State University, and Reed College, but his interests changed to statistics and he joined Wilks at Princeton. After periods at Syracuse, UCLA, and Columbia, Scheffé settled in Berkeley from 1953. His research increasingly focused on linear models and particularly ANOVA, on which he produced a celebrated monograph. His death was the result of a bicycle accident.
Weighted data

Example 6

oneway can work with both weighted and unweighted data. Let’s assume that we wish to perform a one-way layout of the death rate on the four census regions of the United States using state data. Our data contain three variables, \texttt{drate} (the death rate), \texttt{region} (the region), and \texttt{pop} (the population of the state).

To fit the model, we type \texttt{oneway drate region [weight=pop]}, although we typically abbreviate \texttt{weight} as \texttt{w}. We will also add the \texttt{tabulate} option to demonstrate how the table of summary statistics differs for weighted data:

\begin{verbatim}
. use http://www.stata-press.com/data/r14/census8
   (1980 Census data by state)
. oneway drate region [w=pop], tabulate
   (analytic weights assumed)
\end{verbatim}

\begin{verbatim}
Census       Summary of Death rate       Obs.
region                   Mean      Std. Dev.     Freq.     
NE        97.15       5.82    49135283      9
N Cntrl    88.10       5.58    58865670     12
South      87.05     10.40     74734029     16
West       75.65       8.23   43172490     13
Total      87.34     10.43  225907472     50
\end{verbatim}

\begin{verbatim}
Analysis of Variance
Source          SS      df     MS      F    Prob > F
Between groups  2360.92281  3   786.974272 12.17   0.0000
Within groups   2974.09635 46  64.6542685
Total           5335.01916 49 108.877942

Bartlett’s test for equal variances: chi2(3) = 5.4971 Prob>chi2 = 0.139
\end{verbatim}

When the data are weighted, the summary table has four columns rather than three. The column labeled “Freq.” reports the sum of the weights. The overall frequency is $2.259 \times 10^8$, meaning that there are approximately 226 million people in the United States.

The ANOVA table is appropriately weighted. Also see [\texttt{U} 11.1.6 weight].

Methods and formulas

Methods and formulas are presented under the following headings:

\textit{One-way analysis of variance}
\textit{Bartlett’s test}
\textit{Multiple-comparison tests}

\textbf{One-way analysis of variance}

The model of one-way ANOVA is

\[ y_{ij} = \mu + \alpha_i + \epsilon_{ij} \]

for levels \( i = 1, \ldots, k \) and observations \( j = 1, \ldots, n_i \). Define \( \bar{y}_j \) as the (weighted) mean of \( y_{ij} \) over \( j \) and \( \bar{y} \) as the overall (weighted) mean of \( y_{ij} \). Define \( w_{ij} \) as the weight associated with \( y_{ij} \), which is 1 if the data are unweighted. \( w_{ij} \) is normalized to sum to \( n = \sum_i n_i \) if \texttt{aweights} are used and is otherwise not normalized. \( w_i \) refers to \( \sum_j w_{ij} \), and \( w \) refers to \( \sum_i w_i \).

The between-group sum of squares is then

\[ S_1 = \sum_i w_i (\bar{y}_i - \bar{y})^2 \]

The TSS is

\[ S = \sum_i \sum_j w_{ij} (y_{ij} - \bar{y})^2 \]

The within-group sum of squares is given by \( S_c = S - S_1 \).

The between-group mean square is \( s_1^2 = S_1/(k-1) \), and the within-group mean square is \( s_c^2 = S_c/(w-k) \). The test statistic is \( F = s_1^2/s_c^2 \). See, for instance, Snedecor and Cochran (1989).

\textbf{Bartlett’s test}

Bartlett’s test assumes that you have \( m \) independent, normal, random samples and tests the hypothesis \( \sigma_1^2 = \sigma_2^2 = \cdots = \sigma_m^2 \). The test statistic, \( M \), is defined as

\[ M = \frac{(T - m) \ln \hat{\sigma}^2 - \sum (T_i - 1) \ln \hat{\sigma}_i^2}{1 + \frac{1}{3(m-1)} \left\{ \left( \sum \frac{1}{T_i-1} \right) - \frac{1}{T-m} \right\}} \]
where there are $T$ overall observations, $T_i$ observations in the $i$th group, and

$$(T_i - 1)\hat{\sigma}_i^2 = \sum_{j=1}^{T_i} (y_{ij} - \bar{y}_i)^2$$

$$(T - m)\hat{\sigma}^2 = \sum_{i=1}^{m} (T_i - 1)\hat{\sigma}_i^2$$

An approximate test of the homogeneity of variance is based on the statistic $\hat{M}$ with critical values obtained from the $\chi^2$ distribution of $m - 1$ degrees of freedom. See Bartlett (1937) or Draper and Smith (1998, 56–57).

**Multiple-comparison tests**

Let’s begin by reviewing the logic behind these adjustments. The “standard” $t$ statistic for the comparison of two means is

$$t = \frac{\bar{y}_i - \bar{y}_j}{s\sqrt{\frac{1}{n_i} + \frac{1}{n_j}}}$$

where $s$ is the overall standard deviation, $\bar{y}_i$ is the measured average of $y$ in group $i$, and $n_i$ is the number of observations in the group. We perform hypothesis tests by calculating this $t$ statistic. We simultaneously choose a critical level, $\alpha$, and look up the $t$ statistic corresponding to that level in a table. We reject the hypothesis if our calculated $t$ exceeds the value we looked up. Alternatively, because we have a computer at our disposal, we calculate the significance level $e$ corresponding to our calculated $t$ statistic, and if $e < \alpha$, we reject the hypothesis.

This logic works well when we are performing one test. Now consider what happens when we perform several separate tests, say, $n$ of them. Let’s assume, just for discussion, that we set $\alpha$ equal to 0.05 and that we will perform six tests. For each test, we have a 0.05 probability of falsely rejecting the equality-of-means hypothesis. Overall, then, our chances of falsely rejecting at least one of the hypotheses is $1 - (1 - 0.05)^6 \approx 0.26$ if the tests are independent.

The idea behind multiple-comparison tests is to control for the fact that we will perform multiple tests and to reduce our overall chances of falsely rejecting each hypothesis to $\alpha$ rather than letting our chances increase with each additional test. (See Miller [1981] and Hochberg and Tamhane [1987] for rather advanced texts on multiple-comparison procedures.)

The Bonferroni adjustment (see Miller [1981]; also see van Belle et al. [2004, 534–537]) does this by (falsely but approximately) asserting that the critical level we should use, $a$, is the true critical level, $\alpha$, divided by the number of tests, $n$; that is, $a = \alpha / n$. For instance, if we are going to perform six tests, each at the 0.05 significance level, we want to adopt a critical level of $0.05 / 6 \approx 0.00833$.

We can just as easily apply this logic to $e$, the significance level associated with our $t$ statistic, as to our critical level $\alpha$. If a comparison has a calculated significance of $e$, then its “real” significance, adjusted for the fact of $n$ comparisons, is $n \times e$. If a comparison has a significance level of, say, 0.012, and we perform six tests, then its “real” significance is 0.072. If we adopt a critical level of 0.05, we cannot reject the hypothesis. If we adopt a critical level of 0.10, we can reject it.

Of course, this calculation can go above 1, but that just means that there is no $\alpha < 1$ for which we could reject the hypothesis. (This situation arises because of the crude nature of the Bonferroni adjustment.) Stata handles this case by simply calling the significance level 1. Thus the formula for the Bonferroni significance level is

$$e_b = \min(1, en)$$

where $n = k(k - 1)/2$ is the number of comparisons.
The Šidák adjustment (Šidák [1967]; also see Winer, Brown, and Michels [1991, 165–166]) is slightly different and provides a tighter bound. It starts with the assertion that

\[ a = 1 - (1 - \alpha)^{1/n} \]

Turning this formula around and substituting calculated significance levels, we obtain

\[ e_s = \min\{1, 1 - (1 - e)^n\} \]

For example, if the calculated significance is 0.012 and we perform six tests, the “real” significance is approximately 0.07.

The Scheffé test (Scheffé [1953, 1959]; also see Kuehl [2000, 97–98]) differs in derivation, but it attacks the same problem. Let there be \( k \) means for which we want to make all the pairwise tests. Two means are declared significantly different if

\[ t \geq \sqrt{(k - 1)F(\alpha; k - 1, \nu)} \]

where \( F(\alpha; k - 1, \nu) \) is the \( \alpha \)-critical value of the \( F \) distribution with \( k - 1 \) numerator and \( \nu \) denominator degrees of freedom. Scheffé’s test has the nicety that it never declares a contrast significant if the overall \( F \) test is not significant.

Turning the test around, Stata calculates a significance level

\[ \hat{e} = F\left(\frac{t^2}{k - 1}, k - 1, \nu\right) \]

For instance, you have a calculated \( t \) statistic of 4.0 with 50 degrees of freedom. The simple \( t \) test says that the significance level is 0.00021. The \( F \) test equivalent, 16 with 1 and 50 degrees of freedom, says the same. If you are comparing three means, however, you calculate an \( F \) test of 8.0 with 2 and 50 degrees of freedom, which says that the significance level is 0.0010.

oprobit — Ordered probit regression

Description

oprobit fits ordered probit models of ordinal variable depvar on the independent variables indepvars. The actual values taken on by the dependent variable are irrelevant, except that larger values are assumed to correspond to “higher” outcomes.

Quick start

Ordinal probit model of y on x1 and categorical variables a and b

```
oprobit y x1 i.a i.b
```

Model of y on x1 and a one-period lagged value of x1 using tsset data

```
oprobit y x1 L.x1
```

As above, but calculate results for each level of catvar and save statistics to myfile.dta

```
statsby, by(catvar) saving(myfile): oprobit y x1 L.x1
```

Menu

Statistics > Ordinal outcomes > Ordered probit regression

```

SE/Robust

```
vce(vcetype)
```

specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
Reporting

level(#)\>; see [\texttt{R}] estimation options.

nocnsreport; see [\texttt{R}] estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabel, fvwrap(#), fvwrap(style), cformat(\%fmt), pformat(\%fmt), sformat(\%fmt), and nolstretch; see [\texttt{R}] estimation options.

Maximization

maximize_options: difficult, technique(algorithm_spec), iterate(#), [\texttt{no}] log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [\texttt{R}] maximize. These options are seldom used.

The following option is available with oprobit but is not shown in the dialog box: coeflegend; see [\texttt{R}] estimation options.

Remarks and examples

An ordered probit model is used to estimate relationships between an ordinal dependent variable and a set of independent variables. An \textit{ordinal} variable is a variable that is categorical and ordered, for instance, “poor”, “good”, and “excellent”, which might indicate a person’s current health status or the repair record of a car. If there are only two outcomes, see [\texttt{R}] logistic, [\texttt{R}] logit, and [\texttt{R}] probit. This entry is concerned only with more than two outcomes. If the outcomes cannot be ordered (for example, residency in the north, east, south, or west), see [\texttt{R}] mlogit. This entry is concerned only with models in which the outcomes can be ordered. See [\texttt{R}] logistic for a list of related estimation commands.

In ordered probit, an underlying score is estimated as a linear function of the independent variables and a set of cutpoints. The probability of observing outcome \(i\) corresponds to the probability that the estimated linear function, plus random error, is within the range of the cutpoints estimated for the outcome:

\[
\Pr(\text{outcome}_j = i) = \Pr(\kappa_{i-1} < \beta_1 x_{1j} + \beta_2 x_{2j} + \cdots + \beta_k x_{kj} + u_j \leq \kappa_i)
\]

\(u_j\) is assumed to be normally distributed. In either case, we estimate the coefficients \(\beta_1, \beta_2, \ldots, \beta_k\) together with the cutpoints \(\kappa_1, \kappa_2, \ldots, \kappa_{I-1}\), where \(I\) is the number of possible outcomes. \(\kappa_0\) is taken as \(-\infty\), and \(\kappa_I\) is taken as \(+\infty\). All of this is a direct generalization of the ordinary two-outcome probit model.

\textbf{Example 1}

In example 2 of [\texttt{R}] ologit, we use a variation of the automobile dataset (see [\texttt{U}] 1.2.2 Example datasets) to analyze the 1977 repair records of 66 foreign and domestic cars. We use ordered logit to explore the relationship of rep77 in terms of foreign (origin of manufacture), length (a proxy for size), and mpg. Here we fit the same model using ordered probit rather than ordered logit:
. use http://www.stata-press.com/data/r14/fullauto
(Automobile Models)
. oprobit rep77 foreign length mpg
Iteration 0:  log likelihood = -89.895098
Iteration 1:  log likelihood = -78.106316
Iteration 2:  log likelihood = -78.020086
Iteration 3:  log likelihood = -78.020025
Iteration 4:  log likelihood = -78.020025
Ordered probit regression
Number of obs  =        66
LR chi2(3)     =     23.75
Prob > chi2    =     0.0000
Log likelihood = -78.020025  Pseudo R2 =      0.1321

rep77        Coef.   Std. Err.      z    P>|z|     [95% Conf. Interval]
------------- -------- -------- -------- -------- ------------------------
  foreign     1.704861   .4246796    4.01  0.000      .8725037    2.537217
 length      .0468675   .0126480     3.71  0.000       .022078   .0716571
 mpg         .1304559   .0378628     3.45  0.001      .0562463    .2046656

/cut1        10.15892   3.076754    4.128577   16.18923  
/cut2        11.21003   3.107527    5.119389   17.30067  
/cut3        13.54613   3.155233    6.361467   18.72975  
/cut4        13.98059   3.218793    7.671874   20.28931  

We find that foreign cars have better repair records, as do larger cars and cars with better mileage ratings.
Stored results

oprobit stores the following in e():

Scalars

- `e(N)` number of observations
- `e(N_cd)` number of completely determined observations
- `e(k_cat)` number of categories
- `e(k)` number of parameters
- `e(k_aux)` number of auxiliary parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(r2_p)` pseudo-R-squared
- `e(ll)` log likelihood
- `e(ll_0)` log likelihood, constant-only model
- `e(N_clust)` number of clusters
- `e(chi2)` \( \chi^2 \)
- `e(p)` significance of model test
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise

Macros

- `e(cmd)` oprobit
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(offset)` linear offset variable
- `e(chi2type)` Wald or LR; type of model \( \chi^2 \) test
- `e(vcex)` `vcetype` specified in `vce()`
- `e(vcetype)` title used to label Std. Err.
- `e(opt)` type of optimization
- `e(which)` max or min; whether optimizer is to perform maximization or minimization
- `e(ml_method)` type of ml method
- `e(user)` name of likelihood-evaluator program
- `e(technique)` maximization technique
- `e(properties)` b V
- `e(predict)` program used to implement `predict`
- `e(marginsdefault)` default `predict()` specification for `margins`
- `e(asbalanced)` factor variables `fvset` as `asbalanced`
- `e(asobserved)` factor variables `fvset` as `asobserved`

Matrices

- `e(b)` coefficient vector
- `e(Cns)` constraints matrix
- `e(ilog)` iteration log (up to 20 iterations)
- `e(gradient)` gradient vector
- `e(cat)` category values
- `e(V)` variance–covariance matrix of the estimators
- `e(V_modelbased)` model-based variance

Functions

- `e(sample)` marks estimation sample

predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [ if ] [ in ] [ , statistic 
outcome(outcome) nooffset ]

predict [type] { stub* | newvarlist } [ if ] [ in ] , scores
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>predicted probabilities; the default</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the linear prediction</td>
</tr>
</tbody>
</table>

If you do not specify outcome(), pr (with one new variable specified) assumes outcome(#1).
You specify one or k new variables with pr, where k is the number of outcomes.
You specify one new variable with xb and stdp.
These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

pr, the default, calculates the predicted probabilities. If you do not also specify the outcome() option, you specify k new variables, where k is the number of categories of the dependent variable. Say that you fit a model by typing oprobit result x1 x2, and result takes on three values. Then you could type predict p1 p2 p3 to obtain all three predicted probabilities. If you specify the outcome() option, you must specify one new variable. Say that result takes on values 1, 2, and 3. Typing predict p1, outcome(1) would produce the same p1.

xb calculates the linear prediction. You specify one new variable, for example, predict linear, xb. The linear prediction is defined, ignoring the contribution of the estimated cutpoints.

stdp calculates the standard error of the linear prediction. You specify one new variable, for example, predict se, stdp.
outcome(outcome) specifies for which outcome the predicted probabilities are to be calculated. outcome() should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc.

nooffset is relevant only if you specified offset(varname) for oprobit. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $x_j b$ rather than as $x_j b + offset_j$.

scores calculates equation-level score variables. The number of score variables created will equal the number of outcomes in the model. If the number of outcomes in the model was $k$, then the first new variable will contain $\partial \ln L / \partial (x_j b)$; the second new variable will contain $\partial \ln L / \partial \kappa_1$; the third new variable will contain $\partial \ln L / \partial \kappa_2$; ...

and the $k$th new variable will contain $\partial \ln L / \partial \kappa_{k-1}$, where $\kappa_i$ refers to the $i$th cutpoint.

**margins**

**Description for margins**

margins estimates margins of response for probabilities and linear predictions.

**Menu for margins**

Statistics > Postestimation

**Syntax for margins**

margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [predict(statistic ...) ...] [options]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>probabilities for each outcome</td>
</tr>
<tr>
<td>pr</td>
<td>probability for a specified outcome</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction for a specified outcome</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

pr defaults to the first outcome.

Statistics not allowed with margins are functions of stochastic quantities other than $e(b)$.

For the full syntax, see [R] margins.
Remarks and examples

See [U] 20 Estimation and postestimation commands for instructions on obtaining the variance–covariance matrix of the estimators, predicted values, and hypothesis tests. Also see [R] lrtest for performing likelihood-ratio tests.

Example 1

In example 1 of [R] oprobit, we fit the model oprobit rep77 foreign length mpg. The predict command can be used to obtain the predicted probabilities. We type predict followed by the names of the new variables to hold the predicted probabilities, ordering the names from low to high. In our data, the lowest outcome is “poor” and the highest is “excellent”. We have five categories, so we must type five names following predict; the choice of names is up to us:

```
. use http://www.stata-press.com/data/r14/fullauto
(Automobile Models)
. oprobit rep77 foreign length mpg
(output omitted)
. predict poor fair avg good exc
(option pr assumed; predicted probabilities)
. list make model exc good if rep77>=., sep(4) divider
```

<table>
<thead>
<tr>
<th>make</th>

</tr>
</tbody>
</table>

Technical note

For ordered probit, predict, xb produces \( S_j = x_{1j} \beta_1 + x_{2j} \beta_2 + \cdots + x_{kj} \beta_k \). Ordered probit is identical to ordered logit, except that we use different distribution functions for calculating probabilities. The ordered-probit predictions are then the probability that \( S_j + u \) lies between a pair of cutpoints \( \kappa_{i-1} \) and \( \kappa_i \). The formulas for ordered probit are

\[
\Pr(S_j + u < \kappa) = \Phi(\kappa - S_j) \\
\Pr(S_j + u > \kappa) = 1 - \Phi(\kappa - S_j) = \Phi(S_j - \kappa) \\
\Pr(\kappa_1 < S_j + u < \kappa_2) = \Phi(\kappa_2 - S_j) - \Phi(\kappa_1 - S_j)
\]

Rather than using predict directly, we could calculate the predicted probabilities by hand.

```
. predict pscore, xb
. generate probexc = normal(pscore-_b[/cut4])
. generate probgood = normal(_b[/cut4]-pscore) - normal(_b[/cut3]-pscore)
```

[R] oprobit — Ordered probit regression

[U] 20 Estimation and postestimation commands
**Title**

| orthog — Orthogonalize variables and compute orthogonal polynomials |

<table>
<thead>
<tr>
<th>Description</th>
<th>Quick start</th>
<th>Menu</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>Options for orthog</td>
<td>Options for orthopoly</td>
</tr>
<tr>
<td>Remarks and examples</td>
<td>Methods and formulas</td>
<td>References</td>
</tr>
<tr>
<td>Also see</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

orthog orthogonalizes a set of variables, creating a new set of orthogonal variables (all of type double), using a modified Gram–Schmidt procedure (Golub and Van Loan 2013). The order of the variables determines the orthogonalization; hence, the “most important” variables should be listed first.

Execution time is proportional to the square of the number of variables. With many (>10) variables, orthog will be fairly slow.

orthopoly computes orthogonal polynomials for one variable.

**Quick start**

Generate ox1, ox2, and ox3 containing orthogonalized versions of x1, x2, and x3

orthog x1 x2 x3, generate(ox1 ox2 ox3)

Same as above

orthog x1 x2 x3, generate(ox*)

Generate op1, op2, and op3 containing degree 1, 2, and 3 orthogonal polynomials for x1

orthpoly x1, generate(op1 op2 op3) degree(3)

Same as above

orthpoly x1, generate(op1-op3) degree(3)

As above, and generate matrix op containing coefficients of the orthogonal polynomials

orthpoly x1, generate(op1-op3) degree(3) poly(op)

**orthopoly**

Data > Create or change data > Other variable-creation commands > Orthogonal polynomials
Syntax

Orthogonalize variables

```
orthog [varlist] [if] [in] [weight], generate(newvarlist) [matrix(matname)]
```

Compute orthogonal polynomial

```
orthopoly varname [if] [in] [weight],
   {generate(newvarlist) | poly(matname)} [degree(#)]
```

orthopoly requires that generate(newvarlist) or poly(matname), or both, be specified.

varlist may contain time-series operators; see [U] 11.4.4 Time-series varlists.
iweights, aweights, fweights, and pweights are allowed, see [U] 11.1.6 weight.

Options for orthog

- `generate(newvarlist)` is required. generate() creates new orthogonal variables of type double.
  For `orthog`, `newvarlist` will contain the orthogonalized `varlist`. If `varlist` contains `d` variables, then so will `newvarlist`. `newvarlist` can be specified by giving a list of exactly `d` new variable names, or it can be abbreviated using the styles `newvar1-newvar` or `newvar*`. For these two styles of abbreviation, new variables `newvar1`, `newvar2`, ..., `newvar` are generated.

- `matrix(matname)` creates a `(d + 1) × (d + 1)` matrix containing the matrix `R` defined by `X = QR`, where `X` is the `N × (d + 1)` matrix representation of `varlist` plus a column of ones and `Q` is the `N × (d + 1)` matrix representation of `newvarlist` plus a column of ones (`d` = number of variables in `varlist`, and `N` = number of observations).

Options for orthopoly

- `generate(newvarlist)` or `poly()`, or both, must be specified. generate() creates new orthogonal variables of type double. `newvarlist` will contain orthogonal polynomials of degree 1, 2, ..., `d` evaluated at `varname`, where `d` is as specified by `degree(d)`. `newvarlist` can be specified by giving a list of exactly `d` new variable names, or it can be abbreviated using the styles `newvar1-newvar` or `newvar*`. For these two styles of abbreviation, new variables `newvar1`, `newvar2`, ..., `newvar` are generated.

- `poly(matname)` creates a `(d + 1) × (d + 1)` matrix called `matname` containing the coefficients of the orthogonal polynomials. The orthogonal polynomial of degree `i ≤ d` is

  \[ matname[i, d + 1] + matname[i, 1] \times varname + matname[i, 2] \times varname^2 + \cdots + matname[i, i] \times varname^i \]

  The coefficients corresponding to the constant term are placed in the last column of the matrix. The last row of the matrix is all zeros, except for the last column, which corresponds to the constant term.

- `degree(#)` specifies the highest-degree polynomial to include. Orthogonal polynomials of degree 1, 2, ..., `d = #` are computed. The default is `d = 1`. 
Orthogonal variables are useful for two reasons. The first is numerical accuracy for highly collinear variables. Stata’s `regress` and other estimation commands can face much collinearity and still produce accurate results. But, at some point, these commands will drop variables because of collinearity. If you know with certainty that the variables are not perfectly collinear, you may want to retain all their effects in the model. If you use `orthog` or `orthpoly` to produce a set of orthogonal variables, all variables will be present in the estimation results.

Users are more likely to find orthogonal variables useful for the second reason: ease of interpreting results. `orthog` and `orthopoly` create a set of variables such that the “effects” of all the preceding variables have been removed from each variable. For example, if we issue the command

```
. orthog x1 x2 x3, generate(q1 q2 q3)
```

the effect of the constant is removed from `x1` to produce `q1`; the constant and `x1` are removed from `x2` to produce `q2`; and finally the constant, `x1`, and `x2` are removed from `x3` to produce `q3`. Hence,

\[
\begin{align*}
q_1 &= r_{01} + r_{11} x_1 \\
q_2 &= r_{02} + r_{12} x_1 + r_{22} x_2 \\
q_3 &= r_{03} + r_{13} x_1 + r_{23} x_2 + r_{33} x_3
\end{align*}
\]

This effect can be generalized and written in matrix notation as

\[
X = QR
\]

where \( X \) is the \( N \times (d + 1) \) matrix representation of `varlist` plus a column of ones, and \( Q \) is the \( N \times (d + 1) \) matrix representation of `newvarlist` plus a column of ones (\( d \) = number of variables in `varlist` and \( N \) = number of observations). The \( (d + 1) \times (d + 1) \) matrix \( R \) is a permuted upper-triangular matrix, that is, \( R \) would be upper triangular if the constant were first, but the constant is last, so the first row/column has been permuted with the last row/column. Because Stata’s estimation commands list the constant term last, this allows \( R \), obtained via the `matrix()` option, to be used to transform estimation results.

➤ **Example 1: orthog**

Consider Stata’s `auto.dta` dataset. Suppose that we postulate a model in which `price` depends on the car’s `length`, `weight`, `headroom`, and `trunk size` (`trunk`). These predictors are collinear, but not extremely so—the correlations are not that close to 1:

```
. use http://www.stata-press.com/data/r14/auto
   (1978 Automobile Data)
. correlate length weight headroom trunk
   (obs=74)
```

<table>
<thead>
<tr>
<th></th>
<th>length</th>
<th>weight</th>
<th>headroom</th>
<th>trunk</th>
</tr>
</thead>
<tbody>
<tr>
<td>length</td>
<td>1.0000</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>weight</td>
<td>0.9460</td>
<td>1.0000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>headroom</td>
<td>0.5163</td>
<td>0.4835</td>
<td>1.0000</td>
<td></td>
</tr>
<tr>
<td>trunk</td>
<td>0.7266</td>
<td>0.6722</td>
<td>0.6620</td>
<td>1.0000</td>
</tr>
</tbody>
</table>

```
regress certainly has no trouble fitting this model:

\[
\begin{align*}
\text{price} & \quad \text{length} \quad \text{weight} \quad \text{headroom} \quad \text{trunk} \\
\text{Coef.} & \quad -101.7092 \quad 4.753066 \quad -711.5679 \quad 114.0859 \quad 11488.47 \\
\text{Std. Err.} & \quad 42.12534 \quad 1.120054 \quad 445.0204 \quad 4543.902 \\
\text{t} & \quad -2.41 \quad 4.24 \quad -1.60 \quad 2.53 \\
\text{P>|t|} & \quad 0.018 \quad 0.000 \quad 0.114 \quad 0.014 \\
\text{[95% Conf. Interval]} & \quad -185.747 \quad 2.518619 \quad -1599.359 \quad 2423.638 \\
\end{align*}
\]

However, we may believe a priori that length is the most important predictor, followed by weight, headroom, and trunk. We would like to remove the “effect” of length from all the other predictors, remove weight from headroom and trunk, and remove headroom from trunk. We can do this by running orthog, and then we fit the model again using the orthogonal variables:

\[
\begin{align*}
\text{price} & \quad \text{olength} \quad \text{oweight} \quad \text{oheadroom} \quad \text{otrunk} \\
\text{Coef.} & \quad 1265.049 \quad 1175.765 \quad -349.9916 \quad 290.0776 \\
\text{Std. Err.} & \quad 279.5584 \quad 279.5584 \quad 279.5584 \quad 279.5584 \\
\text{t} & \quad 4.53 \quad 4.21 \quad -1.25 \quad 1.04 \\
\text{P>|t|} & \quad 0.000 \quad 0.000 \quad 0.215 \quad 0.303 \\
\text{[95% Conf. Interval]} & \quad 707.3454 \quad 618.0617 \quad -907.6955 \quad -267.6262 \\
\end{align*}
\]

Using the matrix $R$, we can transform the results obtained using the orthogonal predictors back to the metric of original predictors:

\[
\begin{align*}
\text{length} & \quad -101.70924 \quad 4.7530659 \quad -711.56789 \quad 114.08591 \quad 11488.475 \\
\text{weight} & \quad 4.7530659 \quad 1.120054 \quad 445.0204 \quad 4543.902 \\
\text{headroom} & \quad -711.56789 \quad 114.08591 \quad 11488.475 \\
\text{trunk} & \quad 11488.475 \\
\end{align*}
\]

\[\text{Technical note}\]

The matrix $R$ obtained using the $\text{matrix()}$ option with orthog can also be used to recover $X$ (the original $\text{varlist}$) from $Q$ (the orthogonalized $\text{newvarlist}$), one variable at a time. Continuing with the previous example, we illustrate how to recover the trunk variable:
. matrix C = R[1...,"trunk"]
. matrix score double rtrunk = C
. compare rtrunk trunk

<table>
<thead>
<tr>
<th></th>
<th>count</th>
<th>minimum</th>
<th>average</th>
<th>maximum</th>
</tr>
</thead>
<tbody>
<tr>
<td>rtrunk&gt;trunk</td>
<td>74</td>
<td>8.88e-15</td>
<td>1.91e-14</td>
<td>3.55e-14</td>
</tr>
<tr>
<td>jointly defined</td>
<td>74</td>
<td>8.88e-15</td>
<td>1.91e-14</td>
<td>3.55e-14</td>
</tr>
<tr>
<td>total</td>
<td>74</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Here the recovered variable rtrunk is almost exactly the same as the original trunk variable. When you are orthogonalizing many variables, this procedure can be performed to check the numerical soundness of the orthogonalization. Because of the ordering of the orthogonalization procedure, the last variable and the variables near the end of the varlist are the most important ones to check.

The orthpoly command effectively does for polynomial terms what the orthog command does for an arbitrary set of variables.

> Example 2: orthpoly

Again consider the auto.dta dataset. Suppose that we wish to fit the model

\[ \text{mpg} = \beta_0 + \beta_1 \text{weight} + \beta_2 \text{weight}^2 + \beta_3 \text{weight}^3 + \beta_4 \text{weight}^4 + \epsilon \]

We will first compute the regression with natural polynomials:

. generate double w1 = weight
. generate double w2 = w1*w1
. generate double w3 = w2*w1
. generate double w4 = w3*w1
. correlate w1-w4

( obs=74 )

<table>
<thead>
<tr>
<th></th>
<th>w1</th>
<th>w2</th>
<th>w3</th>
<th>w4</th>
</tr>
</thead>
<tbody>
<tr>
<td>w1</td>
<td>1.0000</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>w2</td>
<td>0.9915</td>
<td>1.0000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>w3</td>
<td>0.9665</td>
<td>0.9916</td>
<td>1.0000</td>
<td></td>
</tr>
<tr>
<td>w4</td>
<td>0.9279</td>
<td>0.9679</td>
<td>0.9922</td>
<td>1.0000</td>
</tr>
</tbody>
</table>

. regress mpg w1-w4

Source | SS    | df  | MS      | Number of obs = 74
-------|-------|-----|---------|-------------------
Model   | 1652.73666 | 4 | 413.184164 | F(4, 69) = 36.06 Prob > F = 0.0000

 w4  | -4.86e-13 | 9.14e-13 | -0.53 | 0.596 | -2.31e-12 - 1.34e-12 |
 _cons | 23.94421 | 86.60667 | 0.28 | 0.783 | -148.8314 - 196.7198 |
Some of the correlations among the powers of `weight` are very large, but this does not create any problems for `regress`. However, we may wish to look at the quadratic trend with the constant removed, the cubic trend with the quadratic and constant removed, etc. `orthopoly` will generate polynomial terms with this property:

```
. orthopoly weight, generate(pw*) deg(4) poly(P)
. regress mpg pw1-pw4
```

```
Source | SS      | df   | MS       | Number of obs = 74
--------|---------|------|----------|-------------------
Model   | 1652.73666 | 4    | 413.184164 | F(4, 69) = 36.06
Residual | 790.722803 | 69   | 11.4597508 | Prob > F = 0.0000
Total   | 2443.45946 | 73   | 33.4720474 | R-squared = 0.6764
                          | Adj R-squared = 0.6576
```

```
mpg | Coef.   | Std. Err. | t     | P>|t|    | [95% Conf. Interval]
--- | ------- | --------- | ----- | ------ | -------------------
pw1 | -4.638252 | .3935245  | -11.79 | 0.000 | -5.423312 -3.853192
pw2 | .8263545  | .3935245  | 2.10  | 0.039 | .0412947 1.611414
pw3 | -.3068616 | .3935245  | -0.78 | 0.438 | -1.091921 .4781982
pw4 | -.209457  | .3935245  | -0.53 | 0.596 | -.9945168 .5756028
_cons| 21.2973    | .3935245  | 54.12 | 0.000 | 20.51224 22.08236
```

Compare the \( p \)-values of the terms in the natural polynomial regression with those in the orthogonal polynomial regression. With orthogonal polynomials, it is easy to see that the pure cubic and quartic trends are not significant and that the constant, linear, and quadratic terms each have \( p < 0.05 \).

The matrix \( P \) obtained with the \texttt{poly()} option can be used to transform coefficients for orthogonal polynomials to coefficients for natural polynomials:

```
. orthopoly weight, poly(P) deg(4)
. matrix b = e(b)*P
. matrix list b
```

```
<table>
<thead>
<tr>
<th></th>
<th>deg1</th>
<th>deg2</th>
<th>deg3</th>
<th>deg4</th>
<th>_cons</th>

<td>-.00002291</td>
<td>5.745e-09</td>
<td>-4.862e-13</td>
<td>23.944212</td>
</tr>
</tbody>
</table>
```

## Methods and formulas

`orthog`'s orthogonalization can be written in matrix notation as

\[
X = QR
\]

where \( X \) is the \( N \times (d + 1) \) matrix representation of `varlist` plus a column of ones and \( Q \) is the \( N \times (d + 1) \) matrix representation of `newvarlist` plus a column of ones (\( d = \) number of variables in `varlist`, and \( N = \) number of observations). The \( (d + 1) \times (d + 1) \) matrix \( R \) is a permuted upper-triangular matrix; that is, \( R \) would be upper triangular if the constant were first, but the constant is last, so the first row/column has been permuted with the last row/column.

\( Q \) and \( R \) are obtained using a modified Gram–Schmidt procedure; see Golub and Van Loan (2013, 254–255) for details. The traditional Gram–Schmidt procedure is notoriously unsound, but the modified procedure is good. `orthog` performs two passes of this procedure.

`orthopoly` uses the Christoffel–Darboux recurrence formula (Abramowitz and Stegun 1972).
Both orthog and orthpoly normalize the orthogonal variables such that

\[ Q'WQ = MI \]

where \( W = \text{diag}(w_1, w_2, \ldots, w_N) \) with weights \( w_1, w_2, \ldots, w_N \) (all 1 if weights are not specified), and \( M \) is the sum of the weights (the number of observations if weights are not specified).

[R] regress — Linear regression
**pcorr** displays the partial and semipartial correlation coefficients of a specified variable with each variable in a varlist after removing the effects of all other variables in the varlist. The squared correlations and corresponding significance are also reported.

**Quick start**

Partial and semipartial correlations of v1 with v2, v3, and v4

```
pcorr v1 v2 v3 v4
```

As above, but for each level of categorical variable *catvar*

```
by catvar: pcorr v1 v2 v3 v4
```

Partial and semipartial correlations of v5 with v6, v7, and v8, and a one-period lag of v5 using *tsset* data

```
pcorr v5 L.v5 v6 v7 v8
```

**Menu**

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Partial correlations
Syntax

```
pcorr varname varlist [if] [in] [weight]
```

varlist may contain factor variables; see [U] 11.4.3 Factor variables.

varname and varlist may contain time-series operators; see [U] 11.4.4 Time-series varlists.

by is allowed; see [D] by.

aweights and fweights are allowed; see [U] 11.1.6 weight.

Remarks and examples

Assume that $y$ is determined by $x_1, x_2, \ldots, x_k$. The partial correlation between $y$ and $x_1$ is an attempt to estimate the correlation that would be observed between $y$ and $x_1$ if the other $x$’s did not vary. The semipartial correlation, also called part correlation, between $y$ and $x_1$ is an attempt to estimate the correlation that would be observed between $y$ and $x_1$ after the effects of all other $x$’s are removed from $x_1$ but not from $y$.

Both squared correlations estimate the proportion of the variance of $y$ that is explained by each predictor. The squared semipartial correlation between $y$ and $x_1$ represents the proportion of variance in $y$ that is explained by $x_1$ only. This squared correlation can also be interpreted as the decrease in the model’s $R^2$ value that results from removing $x_1$ from the full model. Thus one could use the squared semipartial correlations as criteria for model selection. The squared partial correlation between $y$ and $x_1$ represents the proportion of variance in $y$ not associated with any other $x$’s that is explained by $x_1$. Thus the squared partial correlation gives an estimate of how much of the variance of $y$ not explained by the other $x$’s is explained by $x_1$.

Example 1

Using our automobile dataset (described in [U] 1.2.2 Example datasets), we can obtain the simple correlations between price, mpg, weight, and foreign from correlate (see [R] correlate):

```
use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
.correlate price mpg weight foreign
(obs=74)
```

```
<table>
<thead>
<tr>
<th></th>
<th>price</th>
<th>mpg</th>
<th>weight</th>
<th>foreign</th>
</tr>
</thead>
<tbody>
<tr>
<td>price</td>
<td>1.0000</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>mpg</td>
<td>-0.4686</td>
<td>1.0000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>weight</td>
<td>0.5386</td>
<td>-0.8072</td>
<td>1.0000</td>
<td></td>
</tr>
<tr>
<td>foreign</td>
<td>0.0487</td>
<td>0.3934</td>
<td>-0.5928</td>
<td>1.0000</td>
</tr>
</tbody>
</table>
```

Although correlate gave us the full correlation matrix, our interest is in just the first column. We find, for instance, that the higher the mpg, the lower the price. We obtain the partial and semipartial correlation coefficients by using pcorr:

```
.pcorr price mpg weight foreign
(obs=74)
```

Partial and semipartial correlations of price with

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>0.0352</td>
<td>0.0249</td>
<td>0.0012</td>
<td>0.0006</td>
<td>0.7693</td>
</tr>
<tr>
<td>weight</td>
<td>0.5488</td>
<td>0.4644</td>
<td>0.3012</td>
<td>0.2157</td>
<td>0.0000</td>
</tr>
<tr>
<td>foreign</td>
<td>0.5402</td>
<td>0.4541</td>
<td>0.2918</td>
<td>0.2062</td>
<td>0.0000</td>
</tr>
</tbody>
</table>
We now find that the partial and semipartial correlations of price with mpg are near 0. In the simple correlations, we found that price and foreign were virtually uncorrelated. In the partial and semipartial correlations, we find that price and foreign are positively correlated. The nonsignificance of mpg tells us that the amount in which $R^2$ decreases by removing mpg from the model is not significant. We find that removing either weight or foreign results in a significant drop in the $R^2$ of the model.

Technical note

Use caution when interpreting the above results. As we said at the outset, the partial and semipartial correlation coefficients are an attempt to estimate the correlation that would be observed if the effects of all other variables were taken out of both $y$ and $x$ or only $x$. pcorr makes it too easy to ignore the fact that we are fitting a model. In the example above, the model is

$$\text{price} = \beta_0 + \beta_1 \text{mpg} + \beta_2 \text{weight} + \beta_3 \text{foreign} + \epsilon$$

which is, in all honesty, a rather silly model. Even if we accept the implied economic assumptions of the model—that consumers value mpg, weight, and foreign—do we really believe that consumers place equal value on every extra 1,000 pounds of weight? That is, have we correctly parameterized the model? If we have not, then the estimated partial and semipartial correlation coefficients may not represent what they claim to represent. Partial and semipartial correlation coefficients are a reasonable way to summarize data if we are convinced that the underlying model is reasonable. We should not, however, pretend that there is no underlying model and that these correlation coefficients are unaffected by the assumptions and parameterization.

Stored results

The pcorr command stores the following in $r()$:

Scalars
- $r(N)$: number of observations
- $r(df)$: degrees of freedom

Matrices
- $r(p_corr)$: partial correlation coefficient vector
- $r(sp_corr)$: semipartial correlation coefficient vector

Methods and formulas

Results are obtained by fitting a linear regression of varname on varlist; see [R] regress. The partial correlation coefficient between varname and each variable in varlist is then calculated as

$$\frac{t}{\sqrt{t^2 + n - k}}$$

(Greene 2012, 37), where $t$ is the $t$ statistic, $n$ is the number of observations, and $k$ is the number of independent variables, including the constant but excluding any dropped variables.
The semipartial correlation coefficient between `varname` and each variable in `varlist` is calculated as

\[ \text{sign}(t) \sqrt{ \frac{t^2(1 - R^2)}{n - k} } \]

(Cohen et al. 2003, 89), where \( R^2 \) is the model \( R^2 \) value, and \( t, n, \) and \( k \) are as described above.

The significance is given by \( 2P( t_{n-k} > |t| ) \), where \( t_{n-k} \) follows a Student’s \( t \) distribution with \( n - k \) degrees of freedom.

**Acknowledgment**

The addition of semipartial correlation coefficients to `pcorr` is based on the `pcorr2` command by Richard Williams of the Department of Sociology at the University of Notre Dame.

permute estimates \( p \)-values for permutation tests on the basis of Monte Carlo simulations. Typing

\[ . \text{permute} \ permvar \ exp\_list, \text{reps}(\#): \text{command} \]

randomly permutes the values in \( permvar \# \) times, each time executing \( \text{command} \) and collecting the associated values from the expression in \( exp\_list \).

These \( p \)-value estimates can be one-sided: \( \Pr(T^* \leq T) \) or \( \Pr(T^* \geq T) \). The default is two-sided: \( \Pr(|T^*| \geq |T|) \). Here \( T^* \) denotes the value of the statistic from a randomly permuted dataset, and \( T \) denotes the statistic as computed on the original data.

\( permvar \) identifies the variable whose observed values will be randomly permuted.

\( command \) defines the statistical command to be executed. Most Stata commands and user-written programs can be used with \( permute \), as long as they follow standard Stata syntax; see [U] 11 Language syntax. The by prefix may not be part of \( command \).

\( exp\_list \) specifies the statistics to be collected from the execution of \( command \).

\( permute \) may be used for replaying results, but this feature is appropriate only when a dataset generated by \( permute \) is currently in memory or is identified by the using option. The variables specified in \( varlist \) in this context must be present in the respective dataset.

### Quick start

Estimate \( p \)-values for a permutation test of \( \Pr(|T^*| \geq |T|) \) for the sum of \( y \) where \( x > 0 \) using nodrop so that permutation of \( y \) is performed using all observations

\[ \text{permute} \ y \ \text{sum}=r(\text{sum}), \text{nodrop}: \text{sum} \ y \ \text{if} \ x \]

As above, but with a one-tailed test for \( \Pr(T^* \geq T) \)

\[ \text{permute} \ y \ \text{sum}=r(\text{sum}), \text{nodrop} \ \text{right}: \text{sum} \ y \ \text{if} \ x \]

As above, but with a one-tailed test for \( \Pr(T^* \leq T) \)

\[ \text{permute} \ y \ \text{sum}=r(\text{sum}), \text{nodrop} \ \text{left}: \text{sum} \ y \ \text{if} \ x \]

Test of \( \text{stat}=r(\text{mystat}) \) returned by program \( \text{myprog} \) permuting values of \( y \)

\[ \text{permute} \ y \ \text{stat}=r(\text{mystat}): \text{myprog} \]

As above, but use 500 replications

\[ \text{permute} \ y \ \text{stat}=r(\text{mystat}), \text{reps}(500): \text{myprog} \]

As above, and save the replicates for each statistic in \( \text{myfile.dta} \)

\[ \text{permute} \ y \ \text{stat}=r(\text{mystat}), \text{reps}(500) \ \text{saving}(\text{myfile}): \text{myprog} \]
Test of \texttt{stat1=r(mystat1)} and \texttt{stat2=r(mystat2)} returned by \texttt{myprog}
\begin{verbatim}
   permute y stat1=r(mystat1) stat2=r(mystat2): myprog
\end{verbatim}

Perform permutations within strata defined by \texttt{svar}
\begin{verbatim}
   permute y stat=r(mystat), strata(svar): myprog
\end{verbatim}

eqno is ##

name

**exp** is a standard Stata expression; see [U] 13 Functions and expressions.

Distinguish between [], which are to be typed, and [], which indicate optional arguments.

### Options

**Main**

reps(\#) specifies the number of random permutations to perform. The default is 100.

left or right requests that one-sided \( p \)-values be computed. If left is specified, an estimate of \( \Pr(T^* \leq T) \) is produced, where \( T^* \) is the test statistic and \( T \) is its observed value. If right is specified, an estimate of \( \Pr(T^* \geq T) \) is produced. By default, two-sided \( p \)-values are computed; that is, \( \Pr(|T^*| \geq |T|) \) is estimated.

**Options**

strata(varlist) specifies that the permutations be performed within each stratum defined by the values of varlist.

saving(filename [, suboptions]) creates a Stata data file (.dta file) consisting of (for each statistic in exp_list) a variable containing the replicates.

double specifies that the results for each replication be saved as doubles, meaning 8-byte reals. By default, they are saved as floats, meaning 4-byte reals.
every(#) specifies that results are to be written to disk every #th replication. every() should be specified only in conjunction with saving() when command takes a long time for each replication. This will allow recovery of partial results should some other software crash your computer. See [P] postfile.

replace specifies that filename be overwritten if it exists. This option does not appear in the dialog box.

Reporting

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [R] level.

noheader suppresses display of the table header. This option implies the nolegend option.

nolegend suppresses display of the table legend. The table legend identifies the rows of the table with the expressions they represent.

verbose requests that the full table legend be displayed. By default, coefficients and standard errors are not displayed.

nodrop prevents permute from dropping observations outside the if and in qualifiers. nodrop will also cause permute to ignore the contents of e(sample) if it exists as a result of running command. By default, permute temporarily drops out-of-sample observations.

nodots suppresses display of the replication dots. By default, one dot character is displayed for each successful replication. A red ‘x’ is displayed if command returns an error or if one of the values in exp_list is missing.

noisily requests that any output from command be displayed. This option implies the nodots option.

trace causes a trace of the execution of command to be displayed. This option implies the noisily option.

title(text) specifies a title to be displayed above the table of permutation results; the default title is Monte Carlo permutation results.

Advanced

eps(#) specifies the numerical tolerance for testing \( |T^*| \geq |T| \), \( T^* \leq T \), or \( T^* \geq T \). These are considered true if, respectively, \( |T^*| \geq |T| - # \), \( T^* \leq T + # \), or \( T^* \geq T - # \). The default is 1e-7. You will not have to specify eps() under normal circumstances.

nowarn suppresses the printing of a warning message when command does not set e(sample).

force suppresses the restriction that command may not specify weights or be a svy command. permute is not suited for weighted estimation, thus permute should not be used with weights or svy. permute reports an error when it encounters weights or svy in command if the force option is not specified. This is a seldom used option, so use it only if you know what you are doing!

reject(exp) identifies an expression that indicates when results should be rejected. When exp is true, the resulting values are reset to missing values.

seed(#) sets the random-number seed. Specifying this option is equivalent to typing the following command prior to calling permute:

. set seed #
Remarks and examples

Permutation tests determine the significance of the observed value of a test statistic in light of rearranging the order (permuting) of the observed values of a variable.

Example 1: A simple two-sample test

Suppose that we conducted an experiment to determine the effect of a treatment on the development of cells. Further suppose that we are restricted to six experimental units because of the extreme cost of the experiment. Thus three units are to be given a placebo, and three units are given the treatment. The measurement is the number of newly developed healthy cells. The following listing gives the hypothetical data, along with some summary statistics.

```
. input y treatment
   y    treatment
   1.  7  0
   2.  9  0
   3. 11  0
   4. 10  1
   5. 12  1
   6. 14  1
7. end

. sort treatment
. summarize y

Variable | Obs | Mean | Std. Dev. | Min | Max
---------|-----|------|-----------|-----|-----
y        | 6   | 10.5 | 2.428992  | 7   | 14  

. by treatment: summarize y

-> treatment = 0

Variable | Obs | Mean | Std. Dev. | Min | Max
---------|-----|------|-----------|-----|-----
y        | 3   | 9    | 2         | 7   | 11  

-> treatment = 1

Variable | Obs | Mean | Std. Dev. | Min | Max
---------|-----|------|-----------|-----|-----
y        | 3   | 12   | 2         | 10  | 14  
```

Clearly, there are more cells in the treatment group than in the placebo group, but a statistical test is needed to conclude that the treatment does affect the development of cells. If the sum of the treatment measures is our test statistic, we can use `permute` to determine the probability of observing 36 or more cells, given the observed data and assuming that there is no effect due to the treatment.
. set seed 1234
. permute y sum=r(sum), saving(permdish) right nodrop nowarn: sum y if treatment
  (running summarize on estimation sample)
Permutation replications (100)
                        1      2      3      4      5
.................................................. 50
.................................................. 100
Monte Carlo permutation results Number of obs =  6
  command:  summarize y if treatment
  sum:  r(sum)
permute var:  y

<table>
<thead>
<tr>
<th></th>
<th>T(obs)</th>
<th>c</th>
<th>n</th>
<th>p=c/n</th>
<th>SE(p)</th>
<th>[95% Conf. Interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>sum</td>
<td>36</td>
<td>6</td>
<td>100</td>
<td>0.0600</td>
<td>0.0237</td>
<td>.0223349 .1260299</td>
</tr>
</tbody>
</table>

Note: Confidence interval is with respect to p=c/n.
Note: c = #{T >= T(obs)}

We see that 6 of the 100 randomly permuted datasets yielded sums from the treatment group larger than or equal to the observed sum of 36. Thus the evidence is not strong enough, at the 5% level, to reject the null hypothesis that there is no effect of the treatment.

Because of the small size of this experiment, we could have calculated the exact permutation $p$-value from all possible permutations. There are six units, but we want the sum of the treatment units. Thus there are $\binom{6}{3} = 20$ permutation sums from the possible unique permutations.

$$
\begin{align*}
7 + 9 + 10 &= 26 \\
7 + 9 + 11 &= 27 \\
7 + 9 + 12 &= 28 \\
7 + 9 + 14 &= 29 \\
7 + 10 + 11 &= 30 \\
7 + 10 + 12 &= 31 \\
7 + 10 + 14 &= 32 \\
7 + 11 + 12 &= 33 \\
7 + 11 + 14 &= 34 \\
7 + 12 + 14 &= 35 \\
9 + 10 + 11 &= 31 \\
9 + 10 + 12 &= 32 \\
9 + 10 + 14 &= 33 \\
9 + 11 + 12 &= 34 \\
9 + 11 + 14 &= 35 \\
9 + 12 + 14 &= 36 \\
10 + 11 + 12 &= 33 \\
10 + 11 + 14 &= 35 \\
10 + 12 + 14 &= 37 \\
11 + 12 + 14 &= 38
\end{align*}
$$

Two of the 20 permutation sums are greater than or equal to 36. Thus the exact $p$-value for this permutation test is 0.1. Tied values will decrease the number of unique permutations.

When the `saving()` option is supplied, `permute` saves the values of the permutation statistic to the indicated file, in our case, `permdish.dta`. This file can be used to replay the result of `permute`. The `level()` option controls the confidence level of the confidence interval for the permutation $p$-value. This confidence interval is calculated using `cii` with the reported n (number of nonmissing replications) and c (the counter for events of significance).

Note: Confidence interval is with respect to p=c/n.
Note: c = #{|T| >= |T(obs)|}
Example 2: Permutation tests with ANOVA

Consider some fictional data from a randomized complete-block design in which we wish to determine the significance of five treatments.

```
. use http://www.stata-press.com/data/r14/permute1, clear
. list y treatment in 1/10, abbrev(10)
```

```
y treatment
1. 4.407557 1
2. 5.693386 1
3. 7.099699 1
4. 3.12132 1
5. 5.242648 1
6. 4.280349 2
7. 4.508785 2
8. 4.079967 2
9. 5.904368 2
10. 3.010556 2
```

These data may be analyzed using `anova`.

```
. anova y treatment subject
Number of obs = 50 R-squared = 0.3544
Root MSE = .914159 Adj R-squared = 0.1213
```

```
<table>
<thead>
<tr>

<td>.87388703</td>
<td>1.05</td>
<td>0.3973</td>
</tr>
<tr>
<td>Residual</td>
<td>30.08475</td>
<td>36</td>
<td>.83568751</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>46.602969</td>
<td>49</td>
<td></td>
<td>.951081</td>
<td></td>
</tr>
</tbody>
</table>
```

Suppose that we want to compute the significance of the $F$ statistic for `treatment` by using `permute`. All we need to do is write a short program that will save the result of this statistic for `permute` to use. For example,

```
program panova, rclass
version 14.2
args response fac_intrst fac_other
anova `response' `fac_intrst' `fac_other'
return scalar Fmodel = e(F)
test `fac_intrst'
return scalar F = r(F)
end
```

Now in `panova`, `test` saves the $F$ statistic for the factor of interest in `r(F)`. This is different from `e(F)`, which is the overall model $F$ statistic for the model fit by `anova` that `panova` saves in `r(Fmodel)`. In the following example, we use the `strata()` option so that the treatments are randomly rearranged within each `subject`. It should not be too surprising that the estimated $p$-values are equal for this example, because the two $F$ statistics are equivalent when controlling for differences between subjects. However, we would not expect to always get the same $p$-values every time we reran `permute`. 
. set seed 1234
. permute treatment treatmentF=r(F) modelF=e(F), reps(1000) strata(subject)
> saving(permanova) nodots: panova y treatment subject
Monte Carlo permutation results
Number of strata = 5 Number of obs = 50
command: panova y treatment subject
treatmentF: r(F)
modelF: e(F)
permute var: treatment

<table>
<thead>
<tr>
<th></th>
<th>T(obs)</th>
<th>c</th>
<th>n</th>
<th>p=c/n</th>
<th>SE(p)</th>
<th>[95% Conf. Interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>treatmentF</td>
<td>1.731465</td>
<td>133</td>
<td>1000</td>
<td>0.1330</td>
<td>0.0107</td>
<td>.112558 .1556293</td>
</tr>
<tr>
<td>modelF</td>
<td>1.520463</td>
<td>133</td>
<td>1000</td>
<td>0.1330</td>
<td>0.0107</td>
<td>.112558 .1556293</td>
</tr>
</tbody>
</table>

Note: Confidence intervals are with respect to p=c/n.
Note: c = #{|T| >= |T(obs)|}

Example 3: Wilcoxon rank-sum test

As a final example, let’s consider estimating the p-value of the Z statistic returned by `ranksum`. Suppose that we collected data from some experiment: y is some measure we took on 17 individuals, and group identifies the group that an individual belongs to.

. use http://www.stata-press.com/data/r14/permute2
. list
group  y
      1.  1  6
      2.  1 11
      3.  1 20
      4.  1  2
      5.  1  9
      6.  1  5
      7.  0  2
      8.  0  1
      9.  0  6
     10.  0  0
     11.  0  2
     12.  0  3
     13.  0  3
     14.  0 12
     15.  0  4
     16.  0  1
     17.  0  5

Next we analyze the data using `ranksum` and notice that the observed value of the test statistic (stored as `r(z)`) is −2.02 with an approximate p-value of 0.0434.
The observed value of the rank-sum statistic is 79, with an expected value (under the null hypothesis of no group effect) of 99. There are 17 observations, so the permutation distribution contains \((\binom{17}{6}) = 12,376\) possible values of the rank-sum statistic if we ignore ties. With ties, we have fewer possible values but still too many to want to count them. Thus we use `permute` with 10,000 replications and see that the Monte Carlo permutation test agrees with the result of the test based on the normal approximation.

For an application of a permutation test to a problem in epidemiology, see Hayes and Moulton (2009, 190–193).

Technical note

`permute` reports confidence intervals for \(p\) to emphasize that it is based on the binomial estimator for proportions. When the variability implied by the confidence interval makes conclusions difficult, you may increase the number of replications to determine more precisely the significance of the test statistic of interest. In other words, the value of \(p\) from `permute` will converge to the true permutation \(p\)-value as the number of replications gets arbitrarily large.
Stored results

`permute` stores the following in `r()`:

 Scalars
- `r(N)`: sample size
- `r(N_reps)`: number of requested replications
- `r(level)`: confidence level
- `r(k_exp)`: number of standard expressions
- `r(k_eexp)`: number of `_b/_se` expressions

 Macros
- `r(cmd)`: `permute`
- `r(command)`: following colon
- `r(left)`: left or empty
- `r(right)`: right or empty
- `r(permvar)`: permutation variable
- `r(rngstate)`: random-number state used
- `r(event)`: `T <= T(obs)`, `T >= T(obs)`, or `|T| <= |T(obs)|`

 Matrices
- `r(b)`: observed statistics
- `r(c)`: count when `r(event)` is true
- `r(reps)`: number of nonmissing results
- `r(p)`: observed proportions
- `r(se)`: standard errors of observed proportions
- `r(ci)`: confidence intervals of observed proportions

Also see

[R] bootstrap — Bootstrap sampling and estimation
[R] jackknife — Jackknife estimation
[R] simulate — Monte Carlo simulations
pk — Pharmacokinetic (biopharmaceutical) data

Description

The term pk refers to pharmacokinetic data and the Stata commands, all of which begin with the letters pk, designed to do some of the analyses commonly performed in the pharmaceutical industry. The system is intended for the analysis of pharmacokinetic data, although some of the commands are for general use.

The pk commands are

- **pkexamine** [R]  
  Calculate pharmacokinetic measures
- **pksumm** [R]  
  Summarize pharmacokinetic data
- **pkshape** [R]  
  Reshape (pharmacokinetic) Latin-square data
- **pkcross** [R]  
  Analyze crossover experiments
- **pkequiv** [R]  
  Perform bioequivalence tests
- **pkcollapse** [R]  
  Generate pharmacokinetic measurement dataset

Remarks and examples

Several types of clinical trials are commonly performed in the pharmaceutical industry. Examples include combination trials, multicenter trials, equivalence trials, and active control trials. For each type of trial, there is an optimal study design for estimating the effects of interest. Currently, the pk system can be used to analyze equivalence trials, which are usually conducted using a crossover design; however, it is possible to use a parallel design and still draw conclusions about equivalence.

Equivalence trials assess bioequivalence between two drugs. Although proving that two drugs behave the same is impossible, the United States Food and Drug Administration believes that if the absorption properties of two drugs are similar, the two drugs will produce similar effects and have similar safety profiles. Generally, the goal of an equivalence trial is to assess the equivalence of a generic drug to an existing drug. This goal is commonly accomplished by comparing a confidence interval about the difference between a pharmacokinetic measurement of two drugs with a confidence limit constructed from U.S. federal regulations. If the confidence interval is entirely within the confidence limit, the drugs are declared bioequivalent. Another approach to assessing bioequivalence is to use the method of interval hypotheses testing. pkequiv is used to conduct these tests of bioequivalence.

Several pharmacokinetic measures can be used to ascertain how available a drug is for cellular absorption. The most common measure is the area under the time-versus-concentration curve (AUC). Another common measure of drug availability is the maximum concentration ($C_{\text{max}}$) achieved by the drug during the follow-up period. Stata reports these and other less common measures of drug availability, including the time at which the maximum drug concentration was observed and the duration of the period during which the subject was being measured. Stata also reports the elimination rate, that is, the rate at which the drug is metabolized, and the drug’s half-life, that is, the time it takes for the drug concentration to fall to one-half of its maximum concentration.
pkexamine computes and reports all the pharmacokinetic measures that Stata produces, including four calculations of the area under the time-versus-concentration curve. The standard area under the curve from 0 to the maximum observed time (AUC$_{0,t_{max}}$) is computed using cubic splines or the trapezoidal rule. Additionally, pkexamine also computes the area under the curve from 0 to infinity by extending the standard time-versus-concentration curve from the maximum observed time by using three different methods. The first method simply extends the standard curve by using a least-squares linear fit through the last few data points. The second method extends the standard curve by fitting a decreasing exponential curve through the last few data points. Finally, the third method extends the curve by fitting a least-squares linear regression line on the log concentration. The mathematical details of these extensions are described in Methods and formulas of [R] pkexamine.

Data from an equivalence trial may also be analyzed using methods appropriate to the particular study design. When you have a crossover design, pkcross can be used to fit an appropriate ANOVA model. As an aside, a crossover design is simply a restricted Latin square; therefore, pkcross can also be used to analyze any Latin-square design.

There are some practical concerns when dealing with data from equivalence trials. Primarily, the data must be organized in a manner that Stata can use. The pk commands include pkcollapse and pkshape, which are designed to help transform data from a common format to one that is suitable for analysis with Stata.

In the following example, we illustrate several different data formats that are often encountered in pharmaceutical research and describe how these formats can be transformed to formats that can be analyzed with Stata.

Example 1

Assume that we have one subject and are interested in determining the drug profile for that subject. A reasonable experiment would be to give the subject the drug and then measure the concentration of the drug in the subject’s blood over a given period. For example, here is a part of a dataset from Chow and Liu (2009, 13):

```
. use http://www.stata-press.com/data/r14/auc
. list, abbrev(14)
```

Examining these data, we notice that the concentration quickly increases, plateaus for a short period, and then slowly decreases over time. pkexamine is used to calculate the pharmacokinetic measures of interest. pkexamine is explained in detail in [R] pkexamine. The output is
pk — Pharmacokinetic (biopharmaceutical) data

```
 . pkexamine time conc

   Maximum concentration =  4.7
   Time of maximum concentration =  3
   Time of last observation (Tmax) =  32
   Elimination rate =  0.0279
   Half life =  24.8503

Area under the curve

<table>
<thead>

<td>142.603</td>
<td>107.759</td>
<td>142.603</td>
</tr>
</tbody>
</table>

Fit based on last 3 points.

Clinical trials, however, require that data be collected on more than one subject. There are several ways to enter raw measured data collected on several subjects. It would be reasonable to enter for each subject the drug concentration value at specific points in time. Such data could be

```
1 0 1 4 7 5 3 1
2 0 2 6 5 4 3 2
3 0 1 2 3 5 4 1
```

where conc1 is the concentration at the first measured time, conc2 is the concentration at the second measured time, etc. This format requires that each drug concentration measurement be made at the same time on each subject. Another more flexible way to enter the data is to have an observation with three variables for each time measurement on a subject. Each observation would have a subject ID, the time at which the measurement was made, and the corresponding drug concentration at that time. The data would be

```
id conc1 conc2 conc3 conc4 conc5 conc6 conc7
1 0 1 4 7 5 3 1
2 0 2 6 5 4 3 2
3 0 1 2 3 5 4 1
```
Stata expects the data to be organized in the second form. If your data are organized as described in the first dataset, you will need to use `reshape` to change the data to the second form; see \[D\] `reshape`. Because the data in the second (or long) format contain information for one drug on several subjects, `pksumm` can be used to produce summary statistics of the pharmacokinetic measurements. The output is

```
. pksumm id time concA
```

Until now, we have been concerned with the profile of only one drug. We have characterized the profile of that drug by individual subjects by using \texttt{pkexamine} and by a group of subjects by using \texttt{pksumm}. The goal of an equivalence trial, however, is to compare two drugs, which we will do in the rest of this example.

For equivalence trials, the study design most often used is the crossover design. For a complete discussion of crossover designs, see Ratkowsky, Evans, and Alldredge (1993).

In brief, crossover designs require that each subject be given both treatments at two different times. The order in which the treatments are applied changes between groups. For example, if we had 20 subjects numbered 1–20, the first 10 would receive treatment A during the first period of the study, and then they would be given treatment B. The second 10 subjects would be given treatment B during the first period of the study, and then they would be given treatment A. Each subject in the study will have four variables that describe the observation: a subject identifier, a sequence identifier that indicates the order of treatment, and two outcome variables, one for each treatment. The outcome variables for each subject are the pharmacokinetic measures. The data must be transformed from a series of measurements on individual subjects to data containing the pharmacokinetic measures for each subject. In Stata parlance, this is referred to as a collapse, which can be done with \texttt{pkcollapse}; see [R] \texttt{pkcollapse}.

(output omitted)
pk — Pharmacokinetic (biopharmaceutical) data

This format is similar to the second format described above, except that now we have measurements for two drugs at each time for each subject. We transform these data with \texttt{pkcollapse}:

\begin{verbatim}
. pkcollapse time concA concB, id(id) keep(seq) stat(auc)
................................
. list, sep(8) abbrev(10)
\end{verbatim}

\begin{verbatim}
id seq auc_concA auc_concB
1. 1 1 150.9643 218.5551
2. 2 1 146.7606 133.3201
3. 3 1 160.6548 126.0635
4. 4 1 157.8622 96.1746
5. 5 1 133.6957 188.9038
6. 7 1 160.639 223.6922
7. 8 1 131.2604 104.0139
8. 9 1 168.5186 237.8962
9. 10 2 137.0627 139.7382
10. 12 2 153.4038 202.3942
11. 13 2 163.4593 136.7848
12. 14 2 146.0462 104.5191
13. 15 2 158.1457 165.8654
14. 18 2 147.1977 139.235
15. 19 2 164.9988 166.2391
16. 20 2 145.3823 158.5146
\end{verbatim}

For this example, we chose to use the AUC for two drugs as our pharmacokinetic measure. We could have used any of the measures computed by \texttt{pkexamine}. In addition to the AUCs, the dataset also contains a sequence variable for each subject indicating when each treatment was administered.

The data produced by \texttt{pkcollapse} are in what Stata calls wide format; that is, there is one observation per subject containing two or more outcomes. To use \texttt{pkcross} and \texttt{pkequiv}, we need to transform these data to long format. This goal can be accomplished using \texttt{pkshape}; see \texttt{[R] pkshape}.

Consider the first subject in the dataset. This subject is in sequence one, which means that treatment A was applied during the first period of the study and treatment B was applied in the second period of the study. We need to split the first observation into two observations so that the outcome measure is only in one variable. Also we need two new variables, one indicating the treatment the subject received and another recording the period of the study when the subject received that treatment. We might expect the expansion of the first subject to be

\begin{verbatim}
id sequence auc treat period
1 1 150.9643 A 1
1 1 218.5551 B 2
\end{verbatim}

We see that subject number 1 was in sequence 1, had an AUC of 150.9643 when treatment A was applied in the first period of the study, and had an AUC of 218.5551 when treatment B was applied.

Similarly, the expansion of subject 10 (the first subject in sequence 2) would be

\begin{verbatim}
id sequence auc treat period
10 2 137.0627 B 1
10 2 139.7382 A 2
\end{verbatim}

Here treatment B was applied to the subject during the first period of the study, and treatment A was applied to the subject during the second period of the study.

An additional complication is common in crossover study designs. The treatment applied in the first period of the study might still have some effect on the outcome in the second period. In this example,
each subject was given one treatment followed by another treatment. To get accurate estimates of
treatment effects, it is necessary to account for the effect that the first treatment has in the second
period of the study. This is called the carryover effect. We must, therefore, have a variable that
indicates which treatment was applied in the first treatment period. \texttt{pkshape} creates a variable that
indicates the carryover effect. For treatments applied during the first treatment period, there will never
be a carryover effect. Thus the expanded data created by \texttt{pkshape} for subject 1 will be

\begin{verbatim}
  id  sequence  outcome  treat  period  carry
  1   1         150.9643  A    1       0
  1   1         218.5551  B    2       A
\end{verbatim}

and the data for subject 10 will be

\begin{verbatim}
  id  sequence  outcome  treat  period  carry
  10  2         137.0627  B    1       0
  10  2         139.7382  A    2       B
\end{verbatim}

We \texttt{pkshape} the data:

\begin{verbatim}
   . pkshape id seq auc*, order(ab ba)
   . sort id sequence period
   . list, sep(16)
\end{verbatim}

\begin{verbatim}
 id  sequence  outcome  treat  carry  period
  1.  1         150.9643  1      0      1
  2.  1         218.5551  2      1      2
  3.  2         146.7606  1      0      1
  4.  2         133.3201  2      1      2
  5.  3         160.6548  1      0      1
  6.  3         126.0635  2      1      2
  7.  4         157.8622  1      0      1
  8.  4         96.17461  2      1      2
  9.  5         133.6957  1      0      1
 10.  5         188.9038  2      1      2
 11.  7         160.639  1      0      1
 12.  7         223.6922  2      1      2
 13.  8         131.2604  1      0      1
 14.  8         104.0139  2      1      2
 15.  9         168.5186  1      0      1
 16.  9         237.8962  2      1      2
 17.  10        137.0627  2      0      1
 18.  10        139.7382  1      2      2
 19.  12        153.4038  2      0      1
 20.  12        202.3942  1      2      2
 21.  13        163.4593  2      0      1
 22.  13        136.7848  1      2      2
 23.  14        146.0462  2      0      1
 24.  14        104.5191  1      2      2
 25.  15        158.1457  2      0      1
 26.  15        165.8654  1      2      2
 27.  18        147.1977  2      0      1
 28.  18        139.235  1      2      2
 29.  19        164.9988  2      0      1
 30.  19        166.2391  1      2      2
 31.  20        148.3823  2      0      1
 32.  20        158.5146  1      2      2
\end{verbatim}

As an aside, crossover designs do not require that each subject receive each treatment, but if they
do, the crossover design is referred to as a complete crossover design.
The last dataset is organized in a manner that can be analyzed with Stata. To fit an ANOVA model to these data, we can use `anova` or `pkcross`. To conduct equivalence tests, we can use `pkequiv`. This example is further analyzed in [R] `pkcross` and [R] `pkequiv`.

References

pkcollapse — Generate pharmacokinetic measurement dataset

Description

pkcollapse generates new variables with the pharmacokinetic summary measures of interest. pkcollapse is one of the pk commands. Please read [R] pk before reading this entry.

Quick start

Single concentration, \( v1 \), measured over time, \( tvar \), for patients identified by \( idvar \)

\[
\text{pkcollapse tvar v1, id(idvar)}
\]

Add additional drug concentration data stored in \( v2 \)

\[
\text{pkcollapse tvar v1 v2, id(idvar)}
\]

As above, but use trapezoidal rule for calculating AUC

\[
\text{pkcollapse tvar v1 v2, id(idvar) trapezoid}
\]

As above, and increase the number of data points used to estimate \( \text{AUC}_{0,\infty} \) to 10

\[
\text{pkcollapse tvar v1 v2, id(idvar) trapezoid fit(10)}
\]

Retain variables \( v3 \) and \( v4 \) when collapsing dataset

\[
\text{pkcollapse tvar v1 v2, id(idvar) keep(v3 v4)}
\]

Menu

Statistics > Epidemiology and related > Other > Generate pharmacokinetik measurement dataset
Syntax

```
pkcollapse time concentration [if], id(id_var) [options]
```

Options

- **Main**
  - *id(id_var)* is required and specifies the variable that contains the subject ID over which `pkcollapse` is to operate.
  - `stat(measures)` specifies the measures to be generated. The default is to generate all the measures.
  - `trapezoid` tells Stata to use the trapezoidal rule when calculating the AUC. The default is to use cubic splines, which give better results for most functions. When the curve is irregular, `trapezoid` may give better results.
  - `fit(#)` specifies the number of points to use in estimating the $\text{AUC}_{0,\infty}$. The default is `fit(3)`, the last three points. This number should be viewed as a minimum; the appropriate number of points will depend on your data.
  - `keep(varlist)` specifies the variables to be kept during the collapse. Variables not specified with the `keep()` option will be dropped. When `keep()` is specified, the keep variables are checked to ensure that all values of the variables are the same within *id_var*. 
force forces the collapse, even when the values of the keep() variables are different within the id_var.

nodots suppresses the display of dots during calculation.

Remarks and examples

pkcollapse generates all the summary pharmacokinetic measures.

Example 1

We demonstrate the use of pkcollapse with the data described in [R] pk. We have drug concentration data on 15 subjects. Each subject is measured at 13 time points over a 32-hour period. Some of the records are

Although pksum allows us to view all the pharmacokinetic measures, we can create a dataset with the measures by using pkcollapse.
The resulting dataset, which we will call `pkdata2`, contains 1 observation per subject. This dataset is in wide format. If we want to use `pkcross` or `pkequiv`, we must transform these data to long format, which we do in the last example of [R] `pkshape`.

### Methods and formulas

The statistics generated by `pkcollapse` are described in [R] `pkexamine`.

### Also see

[R] `pk` — Pharmacokinetic (biopharmaceutical) data
pkcross — Analyze crossover experiments

Description

pkcross analyzes data from a crossover design experiment. When analyzing pharmaceutical trial data, if the treatment, carryover, and sequence variables are known, the omnibus test for separability of the treatment and carryover effects is calculated.

pkcross is one of the pk commands. Please read [R] pk before reading this entry.

Quick start

For pharmacokinetic outcome y measured for subjects identified by idvar given treatments treat in sequences identified by seq in periods period with potential carryover effects from previous treatment carry

Sequence, treatment, and period effects for a 2 × 2 design

    pkcross y, param(3) id(idvar) sequence(seq) treatment(treat) period(period) ///

As above, but estimate the carryover effect instead of the sequence effect

    pkcross y, param(1) id(idvar) treatment(treat) period(period) carryover(carry) ///

Only estimate sequence, treatment, and period effects in higher-order designs

    pkcross y, id(idvar) sequence(seq) treatment(treat) carryover(none)

Also estimate carryover effect and omnibus measure of separability of treatment and carryover effects

    pkcross y, model(seq / idvar|seq treat carry period) treatment(treat) carryover(carry) sequence(seq) ///

Menu

Statistics > Epidemiology and related > Other > Analyze crossover experiments
Syntax

pkcross outcome [if] [in] [, options]

options Description

Model
sequence(varname) sequence variable; default is sequence(sequence)
treatment(varname) treatment variable; default is treatment(treat)
period(varname) period variable; default is period(period)
id(varname) ID variable
carryover(varname) name of carryover variable; default is carryover(carry)
carryover(none) omit carryover effects from model; default is carryover(carry)
model(string) specify the model to fit
sequential estimate sequential instead of partial sums of squares

Parameterization
param(3) estimate mean and the period, treatment, and sequence effects; assume no carryover effects exist; the default
param(1) estimate mean and the period, treatment, and carryover effects; assume no sequence effects exist
param(2) estimate mean, period and treatment effects, and period-by-treatment interaction; assume no sequence or carryover effects exist
param(4) estimate mean, period and treatment effects, and period-by-treatment interaction; assume no period or crossover effects exist

Options

sequence(varname) specifies the variable that contains the sequence in which the treatment was administered. If this option is not specified, sequence(sequence) is assumed.
treatment(varname) specifies the variable that contains the treatment information. If this option is not specified, treatment(treat) is assumed.
period(varname) specifies the variable that contains the period information. If this option is not specified, period(period) is assumed.
id(varname) specifies the variable that contains the subject identifiers. If this option is not specified, id(id) is assumed.
carryover(varname|none) specifies the variable that contains the carryover information. If carry(none) is specified, the carryover effects are omitted from the model. If this option is not specified, carryover(carry) is assumed.
model(string) specifies the model to be fit. For higher-order crossover designs, this option can be useful if you want to fit a model other than the default. However, anova (see [R] anova) can also be used to fit a crossover model. The default model for higher-order crossover designs is outcome predicted by sequence, period, treatment, and carryover effects. By default, the model statement is model(sequence period treat carry).
sequential specifies that sequential sums of squares be estimated.
param(#) specifies which of the four parameterizations to use for the analysis of a $2 \times 2$ crossover experiment. This option is ignored with higher-order crossover designs. The default is param(3). See the technical note for $2 \times 2$ crossover designs for more details.

param(3) estimates the overall mean, the period effects, the treatment effects, and the sequence effects, assuming that no carryover effects exist. This is the default parameterization.

param(1) estimates the overall mean, the period effects, the treatment effects, and the carryover effects, assuming that no sequence effects exist.

param(2) estimates the overall mean, the period effects, the treatment effects, and the period-by-treatment interaction, assuming that no sequence or carryover effects exist.

param(4) estimates the overall mean, the sequence effects, the treatment effects, and the sequence-by-treatment interaction, assuming that no period or crossover effects exist. When the sequence by treatment is equivalent to the period effect, this reduces to the third parameterization.

Remarks and examples

pkcross is designed to analyze crossover experiments. Use pkshape first to reshape your data; see [R] pkshape. pkcross assumes that the data were reshaped by pkshape or are organized in the same manner as produced with pkshape. Washout periods are indicated by the number 0. See the technical note in this entry for more information on analyzing $2 \times 2$ crossover experiments.

Technical note

The $2 \times 2$ crossover design cannot be used to estimate more than four parameters because there are only four pieces of information (the four cell means) collected. pkcross uses ANOVA models to analyze the data, so one of the four parameters must be the overall mean of the model, leaving just 3 degrees of freedom to estimate the remaining effects (period, sequence, treatment, and carryover). Thus the model is overparameterized. Estimation of treatment and carryover effects requires the assumption of either no period effects or no sequence effects. Some researchers maintain that estimating carryover effects at the expense of other effects is a bad idea. This is a limitation of this design. pkcross implements four parameterizations for this model. They are numbered sequentially from one to four and are described in Options.

Example 1

Consider the example data published in Chow and Liu (2009, 71) and described in [R] pkshape. We have entered and reshaped the data with pkshape and have variables that identify the subjects, periods, treatments, sequence, and carryover treatment. To compute the ANOVA table, use pkcross:
. use http://www.stata-press.com/data/r14/chowliu
. pkshape id seq period1 period2, order(ab ba)
. pkcross outcome

sequence variable = sequence
period variable = period
treatment variable = treat
carryover variable = carry
id variable = id

Omnibus measure of separability of treatment and carryover = 29.2893%

There is evidence of intersubject variability, but there are no other significant effects. The omnibus
 test for separability is a measure reflecting the degree to which the study design allows the treatment
effects to be estimated independently of the carryover effects. The measure of separability of the
treatment and carryover effects indicates approximately 29% separability, which can be interpreted
as the degree to which the treatment and carryover effects are orthogonal. This is a characteristic
of the design of the study. For a complete discussion, see Ratkowsky, Evans, and Alldredge (1993).
Compared to the output in Chow and Liu (2009), the sequence effect is mislabeled as a carryover effect.
See Ratkowsky, Evans, and Alldredge (1993, sec. 3.2) for a complete discussion of the mislabeling.

By specifying param(1), we obtain parameterization 1 for this model.

. pkcross outcome, param(1)

sequence variable = sequence

</table>

The sequence identifier must be a string with zeros to indicate washout or baseline periods, or a number. If the sequence identifier is numeric, the `order` option must be specified with `pkshape`. If the sequence identifier is a string, `pkshape` will create sequence, period, and treatment identifiers without the `order` option. In this example, the dash is used to indicate a baseline period, which is an invalid code for this purpose. As a result, the data must be encoded; see `[D] encode`.

. encode seq, gen(num_seq)
. pkshape id num_seq period1 period2 period3, order(0aa 0ab 0ba 0bb)

**Total** | 1560.59 | 50

Omnibus measure of separability of treatment and carryover = 64.6447%

In this example, the sequence specifier used dashes instead of zeros to indicate a baseline period during which no treatment was given. For `pkcross` to work, we need to encode the string sequence variable and then use the `order` option with `pkshape`. A word of caution: `encode` does not necessarily choose the first sequence to be sequence 1, as in this example. Always double-check the sequence numbering when using `encode`. 
Example 3

Continuing with the example from \texttt{[R] pkshape}, we fit an ANOVA model.

When the model statement is used and the omnibus measure of separability is desired, specify the variables in the `treatment()`, `carryover()`, and `sequence()` options to `pkcross`.

### Methods and formulas

`pkcross` uses ANOVA to fit models for crossover experiments; see [R] `anova`.

The omnibus measure of separability is

\[ S = 100(1 - V)\% \]

where \( V \) is Cramér’s \( V \) and is defined as

\[
V = \left\{ \frac{\chi^2}{\min(r-1, c-1)} \right\}^{\frac{1}{2}}
\]

The \( \chi^2 \) is calculated as

\[
\chi^2 = \sum_i \sum_j \left\{ \frac{(O_{ij} - E_{ij})^2}{E_{ij}} \right\}
\]

where \( O \) and \( E \) are the observed and expected counts in a table of the number of times each treatment is followed by the other treatments.

**pkequiv — Perform bioequivalence tests**

**Description**

*pkequiv* performs bioequivalence testing for two treatments. By default, *pkequiv* calculates a standard confidence interval symmetric about the difference between the two treatment means. *pkequiv* also calculates confidence intervals symmetric about zero and intervals based on Fieller's theorem. Also, *pkequiv* can perform interval hypothesis tests for bioequivalence.

*pkequiv* is one of the pk commands. Please read [R] pk before reading this entry.

**Quick start**

Classic CI for difference in pharmacokinetic outcome $y1$ between treatments $v1$ given over period $v2$ in sequence $v3$ with subjects identified by $idvar$

```
pkequiv y1 v1 v2 v3 idvar
```

As above, but calculate an exact CI by Fieller’s theorem

```
pkequiv y1 v1 v2 v3 idvar, fieller
```

Schuirmann’s two one-sided tests for bioequivalence

```
pkequiv y1 v1 v2 v3 idvar, tost
```

Specify the two treatments, 2 and 3, that are to be tested for equivalence

```
pkequiv y1 v1 v2 v3 idvar, compare(2 3)
```

**Menu**

Statistics > Epidemiology and related > Other > Bioequivalence tests
Syntax

\[ \texttt{pkequiv outcome treatment period sequence id [if] [in] [ , options]} \]

</tr>
</tbody>
</table>

Options

- \texttt{compare(string)} specifies the two treatments to be tested for equivalence. Sometimes there may be more than two treatments, but the equivalence can be determined only between any two treatments.

- \texttt{limit(#) } specifies the equivalence limit. The default is 0.2. The equivalence limit can be changed only symmetrically; that is, it is not possible to have a 0.15 lower limit and a 0.2 upper limit in the same test.

- \texttt{level(#) } specifies the confidence level, as a percentage, for confidence intervals. The default is \texttt{level(90)}. This setting is not controlled by the \texttt{set level} command.

- \texttt{fieller} specifies that an equivalence interval based on Fieller’s theorem be calculated.

- \texttt{symmetric} specifies that a symmetric equivalence interval be calculated.

- \texttt{anderson} specifies that the Anderson and Hauck (1983) hypothesis test for bioequivalence be computed. This option is ignored when calculating equivalence intervals based on Fieller’s theorem or when calculating a confidence interval that is symmetric about zero.

- \texttt{tost} specifies that the two one-sided hypothesis tests for bioequivalence be computed. This option is ignored when calculating equivalence intervals based on Fieller’s theorem or when calculating a confidence interval that is symmetric about zero.

- \texttt{noboot} prevents the estimation of the probability that the confidence interval lies within the confidence limits. If this option is not specified, this probability is estimated by resampling the data.

Remarks and examples

\texttt{pkequiv} is designed to conduct tests for bioequivalence based on data from a crossover experiment. \texttt{pkequiv} requires that the user specify the \texttt{outcome}, \texttt{treatment}, \texttt{period}, \texttt{sequence}, and \texttt{id} variables. The data must be in the same format as that produced by \texttt{pkshape}; see \texttt{[R pkshape]}. 
Example 1

We have the following data on which we want to conduct a bioequivalence test between treat = A and treat = B.

![](image)

We use the `pkequiv` command to perform the bioequivalence test.

```
. use http://www.stata-press.com/data/r14/pkdata3
. list, sep(4)
```

### Bioequivalence Test Results

Classical confidence interval for bioequivalence

<table>
<thead>
<tr>
<th>[equivalence limits]</th>
<th>[test limits]</th>
</tr>
</thead>
<tbody>
<tr>
<td>difference: -30.296</td>
<td>30.296</td>
</tr>
<tr>
<td>ratio: 80%</td>
<td>120%</td>
</tr>
</tbody>
</table>

Probability test limits are within equivalence limits = 0.6380

Note: Reference treatment = 1
The default output for `pkequiv` shows a confidence interval for the difference of the means (test limits), the ratio of the means, and the federal equivalence limits. The classic confidence interval can be constructed around the difference between the average measure of effect for the two drugs or around the ratio of the average measure of effect for the two drugs. `pkequiv` reports both the difference measure and the ratio measure. For these data, U.S. federal government regulations state that the confidence interval for the difference must be entirely contained within the range $[-30.296, 30.296]$ and between 80% and 120% for the ratio. Here the test limits are within the equivalence limits. Although the test limits are inside the equivalence limits, there is only a 64% assurance that the observed confidence interval will be within the equivalence limits in the long run. This is an interesting case because, although this sample shows bioequivalence, the evaluation of the long-run performance indicates possible problems. These fictitious data were generated with high intersubject variability, which causes poor long-run performance.

If we conduct a bioequivalence test with the data published in Chow and Liu (2009, 71), which we introduced in [R] `pk` and fully described in [R] `pkshape`, we observe that the probability that the test limits are within the equivalence limits is high.

```
. use http://www.stata-press.com/data/r14/chowliu2
. set seed 1
. pkequiv outcome treat period seq id

Classic confidence interval for bioequivalence

<table>
<thead>
<tr>
<th>[equivalence limits]</th>
<th>[ test limits ]</th>
</tr>
</thead>
<tbody>
<tr>
<td>difference:</td>
<td></td>
</tr>
<tr>
<td>-16.512</td>
<td>16.512</td>
</tr>
<tr>
<td>-8.698</td>
<td>4.123</td>
</tr>
<tr>
<td>ratio:</td>
<td></td>
</tr>
<tr>
<td>80%</td>
<td>120%</td>
</tr>
<tr>
<td>89.464%</td>
<td>104.994%</td>
</tr>
</tbody>
</table>

Probability test limits are within equivalence limits = 0.9960
Note: Reference treatment = 1
```

For these data, the test limits are well within the equivalence limits, and the probability that the test limits are within the equivalence limits is 99.8%.

Example 2

We compute a confidence interval that is symmetric about zero:

```
. pkequiv outcome treat period seq id, symmetric

Westlake’s symmetric confidence interval for bioequivalence

<table>
<thead>
<tr>
<th>[Equivalence limits]</th>
<th>[ Test mean ]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test formulation:</td>
<td></td>
</tr>
<tr>
<td>75.145</td>
<td>89.974</td>
</tr>
<tr>
<td>80.272</td>
<td></td>
</tr>
</tbody>
</table>

Note: Reference treatment = 1
```

The reported equivalence limit is constructed symmetrically about the reference mean, which is equivalent to constructing a confidence interval symmetric about zero for the difference in the two drugs. In the output above, we see that the test formulation mean of 80.272 is within the equivalence limits, indicating that the test drug is bioequivalent to the reference drug.
pkequiv displays interval hypothesis tests of bioequivalence if you specify the tost or the anderson option, or both. For example,

```
pkequiv outcome treat period seq id, tost anderson
```

**Classic confidence interval for bioequivalence**

<table>
<thead>
<tr>
<th>[equivalence limits]</th>
<th>[ test limits ]</th>
</tr>
</thead>
<tbody>
<tr>
<td>difference:</td>
<td>ratio:</td>
</tr>
<tr>
<td>-16.512</td>
<td>80%</td>
</tr>
<tr>
<td>16.512</td>
<td>120%</td>
</tr>
<tr>
<td>-8.698</td>
<td>89.464%</td>
</tr>
<tr>
<td>4.123</td>
<td>104.994%</td>
</tr>
</tbody>
</table>

Probability test limits are within equivalence limits = 0.9960

**Schuirmann’s two one-sided tests**

- upper test statistic = -5.036 p-value = 0.000
- lower test statistic = 3.810 p-value = 0.001

**Anderson and Hauck’s test**

- noncentrality parameter = 4.423
- test statistic = -0.613 empirical p-value = 0.0005

Note: Reference treatment = 1

Both of Schuirmann’s one-sided tests are highly significant, suggesting that the two drugs are bioequivalent. A similar conclusion is drawn from the Anderson and Hauck test of bioequivalence.

### Stored results

pkequiv stores the following in r():

- Scalars
  - r(stddev) pooled-sample standard deviation of period differences from both sequences
  - r(uci) upper confidence interval for a classic interval
  - r(lci) lower confidence interval for a classic interval
  - r(delta) delta value used in calculating a symmetric confidence interval
  - r(u3) upper confidence interval for Fieller’s confidence interval
  - r(l3) lower confidence interval for Fieller’s confidence interval

### Methods and formulas

The lower confidence interval for the difference in the two treatments for the classic shortest confidence interval is

\[
L_1 = (\bar{Y}_T - \bar{Y}_R) - t_{(\alpha,n_1+n_2-2)} \hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}
\]

The upper limit is

\[
U_1 = (\bar{Y}_T - \bar{Y}_R) + t_{(\alpha,n_1+n_2-2)} \hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}
\]
The limits for the ratio measure are

\[ L_2 = \left( \frac{L_1}{Y_R} + 1 \right) 100\% \]

and

\[ U_2 = \left( \frac{U_1}{Y_R} + 1 \right) 100\% \]

where \( \bar{Y}_T \) is the mean of the test formulation of the drug, \( \bar{Y}_R \) is the mean of the reference formulation of the drug, and \( t_{(\alpha, n_1 + n_2 - 2)} \) is the \( t \) distribution with \( n_1 + n_2 - 2 \) degrees of freedom. \( \hat{\sigma}_d \) is the pooled sample variance of the period differences from both sequences, defined as

\[ \hat{\sigma}_d = \frac{1}{n_1 + n_2 - 2} \sum_{k=1}^{n_k} \sum_{i=1}^{n_k} (d_{ik} - \bar{d}_k)^2 \]

The finite sample performance of the classical confidence interval is assessed via bootstrap simulation of the confidence interval. One thousand bootstrap samples are drawn using the patient IDs as clusters. For each sample, the classical confidence interval is constructed and compared with the equivalence limits.

The upper and lower limits for the symmetric confidence interval are \( \bar{Y}_R + \Delta \) and \( \bar{Y}_R - \Delta \), where

\[ \Delta = k_1 \hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2} - (\bar{Y}_T - \bar{Y}_R)} \]

and (simultaneously)

\[ \Delta = -k_2 \hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2} + 2(\bar{Y}_T - \bar{Y}_R)} \]

and \( k_1 \) and \( k_2 \) are computed iteratively to satisfy the above equalities and the condition

\[ \int_{k_1}^{k_2} f(t)dt = 1 - 2\alpha \]

where \( f(t) \) is the probability density function of the \( t \) distribution with \( n_1 + n_2 - 2 \) degrees of freedom.

See Chow and Liu (2009, 88–92) for details about calculating the confidence interval based on Fieller’s theorem.

The two test statistics for the two one-sided tests of equivalence are

\[ T_L = \frac{(\bar{Y}_T - \bar{Y}_R) - \theta_L}{\hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \]

and

\[ T_U = \frac{(\bar{Y}_T - \bar{Y}_R) - \theta_U}{\hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \]

where \(-\theta_L = \theta_U\) and are the regulated confidence limits.
The logic of the Anderson and Hauck test is tricky; see Chow and Liu (2009) for a complete explanation. However, the test statistic is

\[ T_{AH} = \frac{(\bar{Y}_T - \bar{Y}_R) - (\frac{\theta_L + \theta_U}{2})}{\hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \]

and the noncentrality parameter is estimated by

\[ \hat{\delta} = \frac{\theta_U - \theta_L}{2\hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \]

The empirical p-value is calculated as

\[ p = F_t \left( |T_{AH}| - \hat{\delta} \right) - F_t \left( -|T_{AH}| - \hat{\delta} \right) \]

where \( F_t \) is the cumulative distribution function of the t distribution with \( n_1 + n_2 - 2 \) degrees of freedom.

[R] pkequiv — Perform bioequivalence tests
pkexamine — Calculate pharmacokinetic measures

**Description**

pkexamine calculates pharmacokinetic measures from time-and-concentration subject-level data. pkexamine computes and displays the maximum measured concentration, the time at the maximum measured concentration, the time of the last measurement, the elimination time, the half-life, and the area under the concentration-time curve (AUC). Three estimates of the area under the concentration-time curve from 0 to infinity (\(AUC_{0,\infty}\)) are also calculated.

pkexamine is one of the pk commands. Please read [R] pk before reading this entry.

**Quick start**

Pharmacokinetic measures for concentrations \(y\) at times \(tvar\) where \(idvar = 4\)

```
pkexamine tvar y if idvar==4
```

As above, but use trapezoidal rule to calculate \(AUC_{0,t_{max}}\)

```
pkexamine tvar y if idvar==4, trapezoid
```

Plot concentration-time curve where \(idvar = 2\)

```
pkexamine tvar y if idvar==2, graph
```

As above, and save graph as mygraph

```
pkexamine tvar y if idvar==2, graph saving(mygraph)
```

by is allowed; see [D] by.

## Options

### Main

- `fit(#)`: specifies the number of points, counting back from the last measurement, to use in fitting the extension to estimate the AUC\(_{0,\infty}\). The default is `fit(3)`, or the last three points. This value should be viewed as a minimum; the appropriate number of points will depend on your data.

- `trapezoid`: specifies that the trapezoidal rule be used to calculate the AUC. The default is cubic splines, which give better results for most functions. When the curve is irregular, `trapezoid` may give better results.

- `graph`: tells `pkexamine` to graph the concentration-time curve.

- `line` and `log`: specify the estimates of the AUC\(_{0,\infty}\) to display when graphing the AUC\(_{0,\infty}\). These options are ignored, unless they are specified with the `graph` option.

- `exp(#)`: specifies that the exponential fit for the AUC\(_{0,\infty}\) be plotted. You must specify the maximum time value to which you want to plot the curve, and this time value must be greater than the maximum time measurement in the data. If you specify 0, the curve will be plotted to the point at which the linear extension would cross the x axis. This option is not valid with the `line` or `log` option and is ignored, unless the `graph` option is also specified.

### AUC plot

- `cline_options`: affect the rendition of the plotted points connected by lines; see [G-3] `cline_options`.

- `marker_options`: specify the look of markers. This look includes the marker symbol, the marker size, and its color and outline; see [G-3] `marker_options`.
marker_label_options specify if and how the markers are to be labeled; see [G-3] marker_label_options.

addplot(plot) provides a way to add other plots to the generated graph. See [G-3] addplot_option.

twoway_options are any of the options documented in [G-3] twoway_options, excluding by(). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

Remarks and examples

pkexamine computes summary statistics for a given patient in a pharmacokinetic trial. If by idvar: is specified, statistics will be displayed for each subject in the data.

Example 1

Chow and Liu (2009, 13) present data on a study examining primidone concentrations versus time for a subject over a 32-hour period after dosing.

use http://www.stata-press.com/data/r14/auc
list, abbrev(14)

We use \texttt{pkexamine} to produce the summary statistics:

\begin{verbatim}
   . pkexamine time conc, graph

   Maximum concentration = 4.7
   Time of maximum concentration = 3
   Time of last observation (Tmax) = 32
   Elimination rate = 0.0279
   Half life = 24.8503

   Area under the curve

   \begin{tabular}{|c|c|c|c|}
   \hline
   AUC $[0, \text{Tmax}]$ & AUC $[0, \text{inf.}]$ & AUC $[0, \text{inf.}]$ & AUC $[0, \text{inf.}]$
   \hline
   Linear of log conc. & Linear fit & Exponential fit
   \hline
   85.24 & 142.603 & 107.759 & 142.603
   \hline
   \end{tabular}

   Fit based on last 3 points.
\end{verbatim}

The maximum concentration of 4.7 occurs at time 3, and the time of the last observation (Tmax) is 32. In addition to the AUC, which is calculated from 0 to the maximum value of time, \texttt{pkexamine} also reports the area under the curve, computed by extending the curve with each of three methods: a linear fit to the log of the concentration, a linear regression line, and a decreasing exponential regression line. See \textit{Methods and formulas} for details on these three methods.

By default, all extensions to the AUC are based on the last three points. Looking at the graph for these data, it seems more appropriate to use the last seven points to estimate the AUC$[0,\infty)$:

\begin{verbatim}
   . pkexamine time conc, fit(7)

   Maximum concentration = 4.7
   Time of maximum concentration = 3
   Time of last observation (Tmax) = 32
   Elimination rate = 0.0349
   Half life = 19.8354

   Area under the curve

   \begin{tabular}{|c|c|c|c|}
   \hline
   AUC $[0, \text{Tmax}]$ & AUC $[0, \text{inf.}]$ & AUC $[0, \text{inf.}]$ & AUC $[0, \text{inf.}]$
   \hline
   Linear of log conc. & Linear fit & Exponential fit
   \hline
   85.24 & 131.027 & 96.805 & 129.181
   \hline
   \end{tabular}

   Fit based on last 7 points.
\end{verbatim}
This approach decreased the estimate of the $\text{AUC}_{0,\infty}$ for all extensions. To see a graph of the $\text{AUC}_{0,\infty}$ using a linear extension, specify the graph and line options.

```
. pkexamine time conc, fit(7) graph line
```

```
Maximum concentration = 4.7
Time of maximum concentration = 3
Time of last observation (Tmax) = 32
Elimination rate = 0.0349
Half life = 19.8354
```

Area under the curve

<table>
<thead>
<tr>
<th>AUC [0, Tmax]</th>
<th>AUC [0, inf.) Linear of log conc.</th>
<th>AUC [0, inf.) Linear fit</th>
<th>AUC [0, inf.) Exponential fit</th>
</tr>
</thead>
<tbody>
<tr>
<td>85.24</td>
<td>131.027</td>
<td>96.805</td>
<td>129.181</td>
</tr>
</tbody>
</table>

Fit based on last 7 points.

```
Stored results
```

```
pkexamine stores the following in r():
```

Scalars

- `r(auc)`: area under the concentration curve
- `r(half)`: half-life of the drug
- `r(ke)`: elimination rate
- `r(tmax)`: time at last concentration measurement
- `r(cmax)`: maximum concentration
- `r(tomc)`: time of maximum concentration
- `r(auc_line)`: $\text{AUC}_{0,\infty}$ estimated with a linear fit
- `r(auc_exp)`: $\text{AUC}_{0,\infty}$ estimated with an exponential fit
- `r(auc_ln)`: $\text{AUC}_{0,\infty}$ estimated with a linear fit of the natural log
Methods and formulas

Let \( i \) index the observations sorted by time, let \( k \) be the number of observations, and let \( f \) be the number of points specified in the \texttt{fit(\#)} option.

The \( \text{AUC}_{0,t_{\text{max}}} \) is defined as

\[
\text{AUC}_{0,t_{\text{max}}} = \int_0^{t_{\text{max}}} C_t dt
\]

where \( C_t \) is the concentration at time \( t \). By default, the integral is calculated numerically using cubic splines. However, if the trapezoidal rule is used, the \( \text{AUC}_{0,t_{\text{max}}} \) is given as

\[
\text{AUC}_{0,t_{\text{max}}} = \sum_{i=2}^{k} \frac{C_{i-1} + C_i}{2} (t_i - t_{i-1})
\]

The \( \text{AUC}_{0,\infty} \) is the \( \text{AUC}_{0,t_{\text{max}}} + \text{AUC}_{t_{\text{max}},\infty} \), or

\[
\text{AUC}_{0,\infty} = \int_0^{t_{\text{max}}} C_t dt + \int_{t_{\text{max}}}^{\infty} C_t dt
\]

When using the linear extension to the \( \text{AUC}_{0,t_{\text{max}}} \), the integration is cut off when the line crosses the \( x \) axis. The log extension is a linear extension on the log concentration scale. The area for the exponential extension is

\[
\text{AUC}_{0,\infty} = \int_{t_{\text{max}}}^{\infty} e^{-(\beta_0 + t_1)} dt = -\frac{e^{-(\beta_0 + t_{\text{max}})}}{\beta_1}
\]

The elimination rate \( K_{\text{eq}} \) is the negative of the slope from a linear regression of log concentration on time fit to the number of points specified in the \texttt{fit(\#)} option:

\[
K_{\text{eq}} = -\frac{\sum_{i=k-f+1}^{k} (t_i - \bar{t}) (\ln C_i - \ln \bar{C})}{\sum_{i=k-f+1}^{k} (t_i - \bar{t})^2}
\]

The half-life is

\[
t_{\text{half}} = \frac{\ln 2}{K_{\text{eq}}}
\]

[R] pk — Pharmacokinetic (biopharmaceutical) data
pkshape — Reshape (pharmacokinetic) Latin-square data

Description

pkshape reshapes the data for use with anova, pkcross, and pkequiv; see [R] anova, [R] pkcross, and [R] pkequiv. Latin-square and crossover data are often organized in a manner that cannot be analyzed easily with Stata. pkshape reorganizes the data in memory for use in Stata.

pkshape is one of the pk commands. Please read [R] pk before reading this entry.

Quick start

Reshape data when string sequence variable seq = TR or RT for patients identified by idvar observed at tvar1 and tvar2

pkshape idvar seq tvar1 tvar2

As above, but with numeric seq = 1 indicating TR and seq = 2 indicating RT

pkshape idvar seq tvar1 tvar2, order(TR RT)

Indicate that period 2 is a washout and the second treatment is administered in period 3

pkshape idvar seq tvar1 tvar2 tvar3, order(T0R R0T)

Menu

Statistics > Epidemiology and related > Other > Reshape pharmacokinetic latin-square data
Syntax

```plaintext
pkshape id sequence period1 period2 [ period list ] [ , options ]
```

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>order(string)</td>
<td>apply treatments in specified order</td>
</tr>
<tr>
<td>outcome(newvar)</td>
<td>name for outcome variable; default is outcome(outcome)</td>
</tr>
<tr>
<td>treatment(newvar)</td>
<td>name for treatment variable; default is treatment(treat)</td>
</tr>
<tr>
<td>carryover(newvar)</td>
<td>name for carryover variable; default is carryover(carry)</td>
</tr>
<tr>
<td>sequence(newvar)</td>
<td>name for sequence variable; default is sequence(sequence)</td>
</tr>
<tr>
<td>period(newvar)</td>
<td>name for period variable; default is period(period)</td>
</tr>
</tbody>
</table>

Options

- `order(string)` specifies the order in which treatments were applied. If the `sequence()` specifier is a string variable that specifies the order, this option is not necessary. Otherwise, `order()` specifies how to generate the treatment and carryover variables. Any string variable can be used to specify the order. For crossover designs, any washout periods can be indicated with the number 0.

- `outcome(newvar)` specifies the name for the outcome variable in the reorganized data. By default, `outcome(outcome)` is used.

- `treatment(newvar)` specifies the name for the treatment variable in the reorganized data. By default, `treatment(treat)` is used.

- `carryover(newvar)` specifies the name for the carryover variable in the reorganized data. By default, `carryover(carry)` is used.

- `sequence(newvar)` specifies the name for the sequence variable in the reorganized data. By default, `sequence(sequence)` is used.

- `period(newvar)` specifies the name for the period variable in the reorganized data. By default, `period(period)` is used.

Remarks and examples

Often data from a Latin-square experiment are naturally organized in a manner that Stata cannot manage easily. `pkshape` reorganizes Latin-square data so that they can be used with `anova` (see [R] anova) or any pk command. This includes the classic 2 × 2 crossover design commonly used in pharmaceutical research, as well as many other Latin-square designs.

Example 1

Consider the example data published in Chow and Liu (2009, 71). There are 24 patients, 12 in each sequence. Sequence 1 consists of the reference formulation followed by the test formulation; sequence 2 is the test formulation followed by the reference formulation. The measurements reported are the $\text{AUC}_{0-t_{\text{max}}}$ for each patient and for each period.

</table>

Because the outcome for one person is in two different variables, the treatment that was applied to an individual is a function of the period and the sequence. To analyze this treatment using anova, all the outcomes must be in one variable, and each covariate must be in its own variable. To reorganize these data, use pkshape:

. pkshape id seq period1 period2, order(ab ba)
. sort seq id treat
Now the data are organized into separate variables that indicate each factor level for each of the covariates, so the data may be used with `anova` or `pkcross`; see [R] `anova` and [R] `pkcross`.

</table>
```
Consider the study of background music on bank teller productivity published in Kutner et al. (2005). The data are:

<table>
<thead>
<tr>
<th>Week</th>
<th>Monday</th>
<th>Tuesday</th>
<th>Wednesday</th>
<th>Thursday</th>
<th>Friday</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>18(D)</td>
<td>17(C)</td>
<td>14(A)</td>
<td>21(B)</td>
<td>17(E)</td>
</tr>
<tr>
<td>2</td>
<td>13(C)</td>
<td>34(B)</td>
<td>21(E)</td>
<td>16(A)</td>
<td>15(D)</td>
</tr>
<tr>
<td>3</td>
<td>7(A)</td>
<td>29(D)</td>
<td>32(B)</td>
<td>27(E)</td>
<td>13(C)</td>
</tr>
<tr>
<td>4</td>
<td>17(E)</td>
<td>13(A)</td>
<td>24(C)</td>
<td>31(D)</td>
<td>25(B)</td>
</tr>
<tr>
<td>5</td>
<td>21(B)</td>
<td>26(E)</td>
<td>26(D)</td>
<td>31(C)</td>
<td>7(A)</td>
</tr>
</tbody>
</table>

The numbers are the productivity scores, and the letters represent the treatment. We entered the data into Stata:

```
. use http://www.stata-press.com/data/r14/music, clear
. list
 id   seq  day1  day2  day3  day4  day5
  1.   dca   18   17   14   21   17
  2.   cba   13   34   21   16   15
  3.   adbc  7    29   32   27   13
  4.   ecbd  17   13   24   31   25
  5.   bca   21   26   26   31   7
```

We reshape these data with `pkshape`:

```
. pkshape id seq day1 day2 day3 day4 day5
. list, sep(0)
```

```
 id   sequence   outcome    treat carry period
  1.   3    1     7     1     0     0     1
  2.   5    2     21    3     0     1
  3.   2    3     13    5     0     1
  4.   1    4     18    2     0     1
  5.   4    5     17    4     0     1
  6.   3    1     29    2     1     2
  7.   5    2     26    4     3     2
  8.   2    3     34    3     5     2
  9.   1    4     17    5     2     2
 10.   4    5     13    1     4     2
 11.   3    1     32    3     2     3
 12.   5    2     26    2     4     3
 13.   2    3     21    4     3     3
 14.   1    4     14    1     5     3
 15.   4    5     24    5     1     3
 16.   3    1     27    4     3     4
 17.   5    2     31    5     2     4
 18.   2    3     16    1     4     4
 19.   1    4     21    3     1     4
 20.   4    5     31    2     5     4
 21.   3    1     13    5     4     5
 22.   5    2     7     1     5     5
 23.   2    3     15    2     1     5
 24.   1    4     17    4     3     5
 25.   4    5     25    3     2     5
```
Here the sequence variable is a string variable that specifies how the treatments were applied, so the order option is not used. When the sequence variable is a string and the order is specified, the arguments from the order option are used. We could now produce an ANOVA table:

```
anova outcome seq period treat
```

```
Number of obs = 25           R-squared = 0.8666
Root MSE = 3.96232          Adj R-squared = 0.7331

Source       | Partial SS | df | MS    | F     | Prob>F
---           | -----------|----|-------|-------|--------
Model        | 1223.6      | 12 | 101.96667 | 6.49  | 0.0014
sequence     | 82          | 4  | 20.5   | 1.31  | 0.3226
period       | 477.2       | 4  | 119.3  | 7.60  | 0.0027
Treat        | 664.4       | 4  | 166.1  | 10.58 | 0.0007
Residual     | 188.4       | 12 | 15.7   |       |        
Total        | 1412        | 24 | 58.833333 |
```

**Example 3**

Consider the Latin-square crossover example published in Kutner et al. (2005). The example is about apple sales given different methods for displaying apples.

```
Pattern Store Week 1 Week 2 Week 3
1  1  1  9(B) 12(C) 15(A)
2  1  4(B) 12(C)  9(A)
2  1  12(A) 14(B)  3(C)
2  1  13(A) 14(B)  3(C)
3  1  7(C) 18(A)  6(B)
3  2  5(C) 20(A)  4(B)
```

We entered the data into Stata:

```
use http://www.stata-press.com/data/r14/applesales, clear
list, sep(2)
```

```
     id  seq  p1  p2  p3  square
  1.  1   1  9  12  15   1
  2.  2   1  4  12   9   2

We call the resulting dataset `pkdata3`. We conduct equivalence testing on the data in [R] `pkequiv`, and we fit an ANOVA model to these data in the third example of [R] `pkcross`.

References

Also see

[R] pk — Pharmacokinetic (biopharmaceutical) data
**pksumm — Summarize pharmacokinetic data**

### Description

pksumm obtains summary measures based on the first four moments from the empirical distribution of each pharmacokinetic measurement and tests the null hypothesis that the distribution of that measurement is normally distributed.

pksumm is one of the pk commands. Please read [R] pk before reading this entry.

### Quick start

Table of pharmacokinetic measures for concentrations `y` at times `tvar` for patients identified by `idvar`

```bash
pksumm idvar tvar y
```

Add a histogram of `AUC_{0,t_{max}}` values

```bash
pksumm idvar tvar y, graph
```

Same as above

```bash
pksumm idvar tvar y, graph stat(auc)
```

As above, but plot `AUC` calculated from 0 to $\infty$ using a linear extension

```bash
pksumm idvar tvar y, graph stat(aucline)
```

As above, but use 10 bins for the histogram

```bash
pksumm idvar tvar y, graph stat(aucline) bin(10)
```

### Menu

## Options

- **trapezoid** specifies that the trapezoidal rule be used to calculate the AUC. The default is cubic splines, which give better results for most situations. When the curve is irregular, the trapezoidal rule may give better results.

- **fit(#)** specifies the number of points, counting back from the last time measurement, to use in fitting the extension to estimate the \( AUC_{0,\infty} \). The default is \( fit(3) \), the last three points. This default should be viewed as a minimum; the appropriate number of points will depend on the data.

- **notimechk** suppresses the check that the follow-up time for all subjects is the same. By default, pksumm expects the maximum follow-up time to be equal for all subjects.

- **nodots** suppresses the progress dots during calculation. By default, a period is displayed for every call to calculate the pharmacokinetic measures.

- **graph** requests a graph of the distribution of the statistic specified with stat().

- **stat(statistic)** specifies the statistic that pksumm should graph. The default is stat(auc). If the graph option is not specified, this option is ignored.
Histogram, Density plots, Y axis, X axis, Titles, Legend, Overall

`histogram_options` are any of the options documented in [R] `histogram`, excluding `by()`. For `pksumm`, `fraction` is the default, not `density`.

Remarks and examples

`pksumm` produces summary statistics for the distribution of nine common pharmacokinetic measurements. If there are more than eight subjects, `pksumm` also computes a test for normality on each measurement. The nine measurements summarized by `pksumm` are listed above and are described in Methods and formulas of [R] `pkexamine`.

Example 1

We demonstrate the use of `pksumm` on a variation of the data described in [R] `pk`. We have drug concentration data on 15 subjects, each measured at 13 time points over a 32-hour period. A few of the records are

```
. use http://www.stata-press.com/data/r14/pksumm
. list, sep(0)
```

\end{verbatim}

For the 15 subjects, the mean $\text{AUC}_{0,t_{\text{max}}}$ is 150.74, and $\sigma^2 = 123.07$. The skewness of $-0.26$ indicates that the distribution is slightly skewed left. The $p$-value of 0.69 for the $\chi^2$ test of normality indicates that we cannot reject the null hypothesis that the distribution is normal.

If we were to consider any of the three variants of the $\text{AUC}_{0,\infty}$, we would see that there is huge variability and that the distribution is heavily skewed. A skewness different from 0 and a kurtosis different from 3 are expected because the distribution of the $\text{AUC}_{0,\infty}$ is not normal.

We now graph the distribution of $\text{AUC}_{0,t_{\text{max}}}$ by specifying the \texttt{graph} option.

\begin{verbatim}
. pksumm id time conc, graph bin(20)

graph, by default, plots $AUC_{0,t_{\text{max}}}$. To plot a graph of one of the other pharmacokinetic measurements, we need to specify the `stat()` option. For example, we can ask Stata to produce a plot of the $AUC_{0,\infty}$ using the log extension:

```
pksumm id time conc, stat(auclog) graph bin(20)
```

Methods and formulas

The $\chi^2$ test for normality is conducted with `sktest`; see `[R] sktest` for more information on the test of normality.

The statistics reported by `pksumm` are identical to those reported by `summarize` and `sktest`; see `[R] summarize` and `[R] sktest`.

Also see

[R] `pk` — Pharmacokinetic (biopharmaceutical) data
Description

`poisson` fits a Poisson regression of `depvar` on `indepvars`, where `depvar` is a nonnegative count variable.

If you have panel data, see `[XT] xtpoisson`.

Quick start

Poisson regression of `y` on `x`
```
poisson y x
```
Add categorical variable `a`
```
poisson y x i.a
```
Add exposure variable `v`
```
poisson y x i.a, exposure(v)
```
With robust standard errors
```
poisson y x i.a, vce(robust)
```
Report results as incidence-rate ratios
```
poisson y x i.a, irr
```
Replace data in memory with the results of running a Poisson regression model on each level of `catvar`
```
statsby, by(catvar) clear: poisson y x
```

Menu

Statistics > Count outcomes > Poisson regression
Syntax

```
poisson depvar [indevars] [if] [in] [weight] [ , options ]
```

**options**

<table>
<thead>

<tr>
<td>exposure(varname_e)</td>
</tr>
<tr>
<td>offset(varname_o)</td>
</tr>
<tr>
<td>constraints(constraints)</td>
</tr>
<tr>
<td>collinear</td>
</tr>
</tbody>
</table>

**SE/Robust**

```
vce(vcetype)
```

| vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife |

**Reporting**

```
level(#)      set confidence level; default is level(95)
irr           report incidence-rate ratios
noconsreport  do not display constraints
display_options control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |
```

**Maximization**

```
maximize     control the maximization process; seldom used
coefflegend  display legend instead of statistics |
```

**indevars** may contain factor variables; see [U] 11.4.3 Factor variables.

depvar, indevars, varname_e, and varname_o may contain time-series operators; see [U] 11.4.4 Time-series varlists.

bootstrap, by, fp, jackknife, mfp, mi estimate, nestreg, rolling, statsby, stepwise, and svy are allowed; see [U] 11.1.10 Prefix commands.

vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

vce() and weights are not allowed with the svy prefix; see [SVY] svy.

fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

coefflegend does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

**Options**

*Model*

- noconstant, exposure(varname_e), offset(varname_o), constraints(constraints), collinear; see [R] estimation options.

*SE/Robust*

```
vce(vcetype)
```

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
Reporting
level(#); see [R] estimation options.

irr reports estimated coefficients transformed to incidence-rate ratios, that is, $e^{\beta_i}$ rather than $\beta_i$.
Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. irr may be specified at estimation or when replaying previously estimated results.

nocnsreport; see [R] estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabeled, fvwrap(#), fvwrapposition(style), cformat(%/fmt), pformat(%/fmt), sformat(%/fmt), and nolstretch; see [R] estimation options.

Maximization

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] maximize. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following option is available with poisson but is not shown in the dialog box:

coefflegend; see [R] estimation options.

Remarks and examples

The basic idea of Poisson regression was outlined by Coleman (1964, 378–379). See Cameron and Trivedi (2013; 2010, chap. 17) and Johnson, Kemp, and Kotz (2005, chap. 4) for information about the Poisson distribution. See Cameron and Trivedi (2013), Long (1997, chap. 8), Long and Freese (2014, chap. 9), McNeil (1996, chap. 6), and Selvin (2011, chap. 6) for an introduction to Poisson regression. Also see Selvin (2004, chap. 5) for a discussion of the analysis of spatial distributions, which includes a discussion of the Poisson distribution. An early example of Poisson regression was Cochran (1940).

Poisson regression fits models of the number of occurrences (counts) of an event. The Poisson distribution has been applied to diverse events, such as the number of soldiers kicked to death by horses in the Prussian army (von Bortkiewicz 1898); the pattern of hits by buzz bombs launched against London during World War II (Clarke 1946); telephone connections to a wrong number (Thorndike 1926); and disease incidence, typically with respect to time, but occasionally with respect to space. The basic assumptions are as follows:

1. There is a quantity called the incidence rate that is the rate at which events occur. Examples are 5 per second, 20 per 1,000 person-years, 17 per square meter, and 38 per cubic centimeter.
2. The incidence rate can be multiplied by exposure to obtain the expected number of observed events. For example, a rate of 5 per second multiplied by 30 seconds means that 150 events are expected; a rate of 20 per 1,000 person-years multiplied by 2,000 person-years means that 40 events are expected; and so on.
3. Over very small exposures $\epsilon$, the probability of finding more than one event is small compared with $\epsilon$.
4. Nonoverlapping exposures are mutually independent.
With these assumptions, to find the probability of \( k \) events in an exposure of size \( E \), you divide \( E \) into \( n \) subintervals \( E_1, E_2, \ldots, E_n \), and approximate the answer as the binomial probability of observing \( k \) successes in \( n \) trials. If you let \( n \to \infty \), you obtain the Poisson distribution.

In the Poisson regression model, the incidence rate for the \( j \)th observation is assumed to be given by

\[
r_j = e^{\beta_0 + \beta_1 x_{1,j} + \cdots + \beta_k x_{k,j}}
\]

If \( E_j \) is the exposure, the expected number of events, \( C_j \), will be

\[
C_j = E_j e^{\beta_0 + \beta_1 x_{1,j} + \cdots + \beta_k x_{k,j}} = e^{\ln(E_j) + \beta_0 + \beta_1 x_{1,j} + \cdots + \beta_k x_{k,j}}
\]

This model is fit by \texttt{poisson}. Without the \texttt{exposure()} or \texttt{offset()} options, \( E_j \) is assumed to be 1 (equivalent to assuming that exposure is unknown), and controlling for exposure, if necessary, is your responsibility.

Comparing rates is most easily done by calculating incidence-rate ratios (IRRs). For instance, what is the relative incidence rate of chromosome interchanges in cells as the intensity of radiation increases; the relative incidence rate of telephone connections to a wrong number as load increases; or the relative incidence rate of deaths due to cancer for females relative to males? That is, you want to hold all the \( x \)'s in the model constant except one, say, the \( i \)th. The IRR for a one-unit change in \( x_i \) is

\[
e^{\ln(E) + \beta_1 x_1 + \cdots + \beta_i (x_i + 1) + \cdots + \beta_k x_k}
\]

More generally, the IRR for a \( \Delta x_i \) change in \( x_i \) is \( e^{\beta_i \Delta x_i} \). The \texttt{lincom} command can be used after \texttt{poisson} to display incidence-rate ratios for any group relative to another; see [R] \texttt{lincom}.

\textbf{Example 1}

\cite{Chatterjee and Hadi 2012,174} give the number of injury incidents and the proportion of flights for each airline out of the total number of flights from New York for nine major U.S. airlines in one year:

\begin{verbatim}
. use http://www.stata-press.com/data/r14/airline
. list

<table>
<thead>
<tr>
<th>airline</th>
<th>injuries</th>
<th>n</th>
<th>XYZowned</th>
</tr>
</thead>
</table>
| 1       | 1        | 11    | 0.0950   | 1
| 2       | 2        | 7     | 0.1920   | 0
| 3       | 3        | 7     | 0.0750   | 0
| 4       | 4        | 19    | 0.2078   | 0
| 5       | 5        | 9     | 0.1382   | 0
| 6       | 6        | 4     | 0.0540   | 1
| 7       | 7        | 3     | 0.1292   | 0
| 8       | 8        | 1     | 0.0503   | 0
| 9       | 9        | 3     | 0.0629   | 1
\end{verbatim}
To their data, we have added a fictional variable, \texttt{XYZowned}. We will imagine that an accusation is made that the airlines owned by XYZ Company have a higher injury rate.

\begin{verbatim}
. poisson injuries XYZowned, exposure(n) irr
Iteration 0:  log likelihood =  -23.027197
Iteration 1:  log likelihood =  -23.027177
Iteration 2:  log likelihood =  -23.027177
Poisson regression  Number of obs =  9
                   LR chi2(1) =  1.77
                   Prob > chi2 = 0.1836
Log likelihood =  -23.027177  Pseudo R2 = 0.0370

          | IRR      Std. Err.     z    P>|z|      [95% Conf. Interval]
----------|----------|-----------------|------|----------|-----------------------------|
    injuries |         |                 |      |          |                            |
 XYZowned   | 1.46347 |   .406872       | 1.37 | 0.171    | 0.8486578 - 2.523675      |
     _cons   | 58.044  |     8.558145    | 27.54| 0.000    | 43.47662 - 77.49281       |
 ln(n)      |         | 1 (exposure)    |      |          |                            |
\end{verbatim}

We specified \texttt{irr} to see the IRRs rather than the underlying coefficients. We estimate that XYZ Airlines’ injury rate is 1.46 times larger than that for other airlines, but the 95% confidence interval is 0.85 to 2.52; we cannot even reject the hypothesis that XYZ Airlines has a lower injury rate.

\section*{Technical note}

In example 1, we assumed that each airline’s exposure was proportional to its fraction of flights out of New York. What if “large” airlines, however, also used larger planes, and so had even more passengers than would be expected, given this measure of exposure? A better measure would be each airline’s fraction of passengers on flights out of New York, a number that we do not have. Even so, we suppose that \texttt{n} represents this number to some extent, so a better estimate of the effect might be

\begin{verbatim}
. generate lnN=ln(n)
. poisson injuries XYZowned lnN
Iteration 0:  log likelihood =  -22.333875
Iteration 1:  log likelihood =  -22.332276
Iteration 2:  log likelihood =  -22.332276
Poisson regression  Number of obs =  9
                   LR chi2(2) = 19.15
                   Prob > chi2 = 0.0001
Log likelihood =  -22.332276  Pseudo R2 = 0.3001

          | Coef.     Std. Err.     z    P>|z|      [95% Conf. Interval]
----------|-----------|-----------------|------|----------|-----------------------------|
    injuries |           |                 |      |          |                            |
 XYZowned   |  .684066 |    .3895877     | 1.76 | 0.079    | -0.0796111 - 1.447645     |
     lnN     | 1.424169 |     .3725155    | 3.82 | 0.000    | 0.6940517 - 2.154285      |
     _cons   | 4.863891 |     .7090501    | 6.86 | 0.000    | 3.474178 - 6.253603       |
\end{verbatim}

Here rather than specifying the \texttt{exposure()} option, we explicitly included the variable that would normalize for exposure in the model. We did not specify the \texttt{irr} option, so we see coefficients rather than IRRs. We started with the model

$$\text{rate} = e^{\beta_0 + \beta_1 \text{XYZowned}}$$

The observed counts are therefore

$$\text{count} = ne^{\beta_0 + \beta_1 \text{XYZowned}} = e^{\ln(n) + \beta_0 + \beta_1 \text{XYZowned}}$$
which amounts to constraining the coefficient on \( \ln(n) \) to 1. This is what was estimated when we specified the `exposure(n)` option. In the above model, we included the normalizing exposure ourselves and, rather than constraining the coefficient to be 1, estimated the coefficient.

The estimated coefficient is 1.42, a respectable distance away from 1, and is consistent with our speculation that larger airlines also use larger airplanes. With this small amount of data, however, we also have a wide confidence interval that includes 1.

Our estimated coefficient on \( XYZ_{owned} \) is now 0.684, and the implied IRR is \( e^{0.684} \approx 1.98 \) (which we could also see by typing `poisson, irr`). The 95% confidence interval for the coefficient still includes 0 (the interval for the IRR includes 1), so although the point estimate is now larger, we still cannot be certain of our results.

Our expert opinion would be that, although there is not enough evidence to support the charge, there is enough evidence to justify collecting more data.

---

**Example 2**

In a famous age-specific study of coronary disease deaths among male British doctors, Doll and Hill (1966) reported the following data (reprinted in Rothman, Greenland, and Lash [2008, 264]):

<table>
<thead>
<tr>
<th>Age</th>
<th>Smokers</th>
<th>Deaths</th>
<th>Person-years</th>
<th>Nonsmokers</th>
<th>Deaths</th>
<th>Person-years</th>
</tr>
</thead>
<tbody>
<tr>
<td>35–44</td>
<td>32</td>
<td>52,407</td>
<td></td>
<td>2</td>
<td>18,790</td>
<td></td>
</tr>
<tr>
<td>45–54</td>
<td>104</td>
<td>43,248</td>
<td></td>
<td>12</td>
<td>10,673</td>
<td></td>
</tr>
<tr>
<td>55–64</td>
<td>206</td>
<td>28,612</td>
<td></td>
<td>28</td>
<td>5,710</td>
<td></td>
</tr>
<tr>
<td>65–74</td>
<td>186</td>
<td>12,663</td>
<td></td>
<td>28</td>
<td>2,585</td>
<td></td>
</tr>
<tr>
<td>75–84</td>
<td>102</td>
<td>5,317</td>
<td></td>
<td>31</td>
<td>1,462</td>
<td></td>
</tr>
</tbody>
</table>

The first step is to enter these data into Stata, which we have done:

```plaintext
.use http://www.stata-press.com/data/r14/dollhill3, clear
.list
```

<table>
<thead>
<tr>
<th>agecat</th>
<th>smokes</th>
<th>deaths</th>
<th>pyyears</th>
</tr>
</thead>
<tbody>
<tr>
<td>35-44</td>
<td>1</td>
<td>32</td>
<td>52407</td>
</tr>
<tr>
<td>45-54</td>
<td>1</td>
<td>104</td>
<td>43248</td>
</tr>
<tr>
<td>55-64</td>
<td>1</td>
<td>206</td>
<td>28612</td>
</tr>
<tr>
<td>65-74</td>
<td>1</td>
<td>186</td>
<td>12663</td>
</tr>
<tr>
<td>75-84</td>
<td>1</td>
<td>102</td>
<td>5317</td>
</tr>
<tr>
<td>35-44</td>
<td>0</td>
<td>2</td>
<td>18790</td>
</tr>
<tr>
<td>45-54</td>
<td>0</td>
<td>12</td>
<td>10673</td>
</tr>
<tr>
<td>55-64</td>
<td>0</td>
<td>28</td>
<td>5710</td>
</tr>
<tr>
<td>65-74</td>
<td>0</td>
<td>28</td>
<td>2585</td>
</tr>
<tr>
<td>75-84</td>
<td>0</td>
<td>31</td>
<td>1462</td>
</tr>
</tbody>
</table>
The most “natural” analysis of these data would begin by introducing indicator variables for each age
category and one indicator for smoking:

```
poisson deaths smokes i.agecat, exposure(pyears) irr
```

```
Iteration 0:  log likelihood = -33.823284
Iteration 1:  log likelihood = -33.600471
Iteration 2:  log likelihood = -33.600153
Iteration 3:  log likelihood = -33.600153
```

Poisson regression

```
Number of obs = 10
LR chi2(5) = 922.93
Prob > chi2 = 0.0000
Log likelihood = -33.600153 Pseudo R2 = 0.9321
```

| deaths         | IRR   | Std. Err. | z    | P>|z| | [95% Conf. Interval] |
|----------------|-------|-----------|------|-----|----------------------|
| smokes         | 1.425519 | .1530638 | 3.30 | 0.001 | 1.154984 1.759421    |
| agecat         |       |          |      |      |                      |
| 45-54          | 4.410584 | .8605197 | 7.61 | 0.000 | 3.009011 6.464997    |
| 55-64          | 13.8392  | 2.542638 | 14.30| 0.000 | 9.654328 19.83809    |
| 65-74          | 28.51678 | 5.269878 | 18.13| 0.000 | 19.85177 40.96395    |
| 75-84          | 40.45121 | 7.775511 | 19.25| 0.000 | 27.75326 58.95885    |
| _cons          | .0003636 | .0000697 | -41.30| 0.000 | .0002497 .0005296    |
| ln(pyears)     | 1 (exposure) |      |       |      |                      |

In the above, we specified `irr` to obtain IRRs. We estimate that smokers have 1.43 times the mortality
rate of nonsmokers. See, however, example 1 in [R] poisson postestimation.

### Stored results

`poisson` stores the following in `e()`:

**Scalars**
- `e(N)` number of observations
- `e(k)` number of parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(r2_p)` pseudo-$R$-squared
- `e(ll)` log likelihood
- `e(ll_0)` log likelihood, constant-only model
- `e(N_clust)` number of clusters
- `e(chi2)` $\chi^2$
- `e(p)` significance
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise
Macros

- `e(cmd)` poisson
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(offset)` linear offset variable
- `e(chi2type)` Wald or LR; type of model $\chi^2$ test
- `e(vce)` vcetype specified in `vce()`
- `e(vctype)` title used to label Std. Err.
- `e(opt)` type of optimization
- `e(which)` max or min; whether optimizer is to perform maximization or minimization
- `e(ml_method)` type of ml method
- `e(user)` name of likelihood-evaluator program
- `e(technique)` maximization technique
- `e(properties)` b V
- `e(estat_cmd)` program used to implement estat
- `e(predict)` program used to implement predict
- `e(asbalanced)` factor variables fvset as asbalanced
- `e(asobserved)` factor variables fvset as asobserved

Matrices

- `e(b)` coefficient vector
- `e(Cns)` constraints matrix
- `e(i1og)` iteration log (up to 20 iterations)
- `e(gradient)` gradient vector
- `e(V)` variance–covariance matrix of the estimators
- `e(V_modelbased)` model-based variance

Functions

- `e(sample)` marks estimation sample

Methods and formulas

The log likelihood (with weights $w_j$ and offsets) is given by

$$\Pr(Y = y) = \frac{e^{-\lambda} \lambda^y}{y!}$$

$$\xi_j = x_j \beta + \text{offset}_j$$

$$f(y_j) = \frac{e^{-\text{exp}(\xi_j)} \cdot e^{\xi_j \cdot y_j}}{y_j!}$$

$$\ln L = \sum_{j=1}^{n} w_j \left\{ -e^{\xi_j} + \xi_j y_j - \ln(y_j!) \right\}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly Maximum likelihood estimators and Methods and formulas.

`poisson` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] variance estimation.
Siméon-Denis Poisson (1781–1840) was a French mathematician and physicist who contributed to several fields: his name is perpetuated in Poisson brackets, Poisson’s constant, Poisson’s differential equation, Poisson’s integral, and Poisson’s ratio. Among many other results, he produced a version of the law of large numbers. His rather misleadingly titled Recherches sur la probabilité des jugements embraces a complete treatise on probability, as the subtitle indicates, including what is now known as the Poisson distribution. That, however, was discovered earlier by the Huguenot–British mathematician Abraham de Moivre (1667–1754).

## Postestimation commands

The following postestimation command is of special interest after `poisson`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>estat gof</code></td>
<td>goodness-of-fit test</td>
</tr>
</tbody>
</table>

`estat gof` is not appropriate after the `svy` prefix.

The following standard postestimation commands are also available:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>contrast</code></td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td><code>estat ic</code></td>
<td>Akaike’s and Schwarz’s Bayesian information criteria (AIC and BIC)</td>
</tr>
<tr>
<td><code>estat summarize</code></td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td><code>estat vce</code></td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td><code>estat (svy)</code></td>
<td>postestimation statistics for survey data</td>
</tr>
<tr>
<td><code>estimates</code></td>
<td>cataloging estimation results</td>
</tr>
<tr>
<td><code>* forecast</code></td>
<td>dynamic forecasts and simulations</td>
</tr>
<tr>
<td><code>* hausman</code></td>
<td>Hausman’s specification test</td>
</tr>
<tr>
<td><code>lincom</code></td>
<td>point estimates, standard errors, testing, and inference for linear combinations of coefficients</td>
</tr>
<tr>
<td><code>linktest</code></td>
<td>link test for model specification</td>
</tr>
<tr>
<td><code>* lrtest</code></td>
<td>likelihood-ratio test</td>
</tr>
<tr>
<td><code>margins</code></td>
<td>marginal means, predictive margins, marginal effects, and average marginal effects</td>
</tr>
<tr>
<td><code>marginsplot</code></td>
<td>graph the results from margins (profile plots, interaction plots, etc.)</td>
</tr>
<tr>
<td><code>nlcom</code></td>
<td>point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients</td>
</tr>
<tr>
<td><code>predict</code></td>
<td>predictions, residuals, influence statistics, and other diagnostic measures</td>
</tr>
<tr>
<td><code>predictnl</code></td>
<td>point estimates, standard errors, testing, and inference for generalized predictions</td>
</tr>
<tr>
<td><code>pwcompare</code></td>
<td>pairwise comparisons of estimates</td>
</tr>
<tr>
<td><code>suest</code></td>
<td>seemingly unrelated estimation</td>
</tr>
<tr>
<td><code>test</code></td>
<td>Wald tests of simple and composite linear hypotheses</td>
</tr>
<tr>
<td><code>testnl</code></td>
<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.
predict

Description for predict

`predict` creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, standard errors, and equation-level scores.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>n</code></td>
<td>number of events; the default</td>
</tr>
<tr>
<td><code>ir</code></td>
<td>incidence rate</td>
</tr>
<tr>
<td><code>pr(n)</code></td>
<td>probability ( \Pr(y_j = n) )</td>
</tr>
<tr>
<td><code>pr(a,b)</code></td>
<td>probability ( \Pr(a \leq y_j \leq b) )</td>
</tr>
<tr>
<td><code>xb</code></td>
<td>linear prediction</td>
</tr>
<tr>
<td><code>stdp</code></td>
<td>standard error of the linear prediction</td>
</tr>
<tr>
<td><code>score</code></td>
<td>first derivative of the log likelihood with respect to ( x_j\beta )</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type `predict ... if e(sample) ... if wanted` only for the estimation sample.

Options for predict

- `Main`

  `n`, the default, calculates the predicted number of events, which is \( \exp(x_j\beta) \) if neither `offset()` nor `exposure()` was specified when the model was fit; \( \exp(x_j\beta + offset_j) \) if `offset()` was specified; or \( \exp(x_j\beta) \times exposure_j \) if `exposure()` was specified.

  `ir` calculates the incidence rate \( \exp(x_j\beta) \), which is the predicted number of events when exposure is 1. Specifying `ir` is equivalent to specifying `n` when neither `offset()` nor `exposure()` was specified when the model was fit.

  `pr(n)` calculates the probability \( \Pr(y_j = n) \), where \( n \) is a nonnegative integer that may be specified as a number or a variable.

  `pr(a,b)` calculates the probability \( \Pr(a \leq y_j \leq b) \), where \( a \) and \( b \) are nonnegative integers that may be specified as numbers or variables;

  \( b \) missing (\( b \geq . \)) means \( +\infty \);

  `pr(20,)` calculates \( \Pr(y_j \geq 20) \);

  `pr(20,b)` calculates \( \Pr(y_j \geq 20) \) in observations for which \( b \geq . \) and calculates \( \Pr(20 \leq y_j \leq b) \) elsewhere.
pr(.,b) produces a syntax error. A missing value in an observation of the variable a causes a missing value in that observation for pr(a,b).

xb calculates the linear prediction, which is \( x_j\beta \) if neither offset() nor exposure() was specified; \( x_j\beta + \text{offset}_j \) if offset() was specified; or \( x_j\beta + \ln(\text{exposure}_j) \) if exposure() was specified; see nooffset below.

stdp calculates the standard error of the linear prediction.

score calculates the equation-level score, \( \partial \ln L / \partial (x_j\beta) \).

nooffset is relevant only if you specified offset() or exposure() when you fit the model. It modifies the calculations made by predict so that they ignore the offset or exposure variable; the linear prediction is treated as \( x_j\beta \) rather than as \( x_j\beta + \text{offset}_j \) or \( x_j\beta + \ln(\text{exposure}_j) \). Specifying predict ..., nooffset is equivalent to specifying predict ..., ir.

**margins**

**Description for margins**

margins estimates margins of response for numbers of events, incidence rates, probabilities, and linear predictions.

**Menu for margins**

Statistics > Postestimation

**Syntax for margins**

```
margins [ marginlist ] [, options ]
margins [ marginlist ] , predict(statistic ...) [ predict(statistic ...) ... ] [ options ]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>number of events; the default</td>
</tr>
<tr>
<td>ir</td>
<td>incidence rate</td>
</tr>
<tr>
<td>pr(n)</td>
<td>probability ( \Pr(y_j = n) )</td>
</tr>
<tr>
<td>pr(a,b)</td>
<td>probability ( \Pr(a \leq y_j \leq b) )</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
<tr>
<td>score</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than \( \mathbf{e}(\mathbf{b}) \).

For the full syntax, see [R] margins.
estat
description for estat

estat gof performs a goodness-of-fit test of the model. Both the deviance statistic and the Pearson statistic are reported. If the tests are significant, the Poisson regression model is inappropriate. Then you could try a negative binomial model; see \[R\] nbreg.

menu for estat

statistics > postestimation

Syntax for estat

estat gof

Remarks and examples

Example 1

Continuing with example 2 of \[R\] poisson, we use estat gof to determine whether the model fits the data well.

. use http://www.stata-press.com/data/r14/dollhill3
. poisson deaths smokes i.agecat, exp(pyears) irr
   (output omitted)
. estat gof

    Deviance goodness-of-fit = 12.13237
    Prob > chi2(4) = 0.0164
    Pearson goodness-of-fit = 11.15533
    Prob > chi2(4) = 0.0249

The deviance goodness-of-fit test tells us that, given the model, we can reject the hypothesis that these data are Poisson distributed at the 1.64% significance level. The Pearson goodness-of-fit test tells us that we can reject the hypothesis at the 2.49% significance level.

So let us now back up and be more careful. We can most easily obtain the incidence-rate ratios within age category by using ir; see \[R\] epitab:

. ir deaths smokes pyears, by(agecat) nohet

<table>
<thead>
<tr>
<th>age category</th>
<th>IRR</th>
<th>[95% Conf. Interval]</th>

We find that the mortality incidence ratios are greatly different within age category, being highest for the youngest categories and actually dropping below 1 for the oldest. (In the last case, we might argue that those who smoke and who have not died by age 75 are self-selected to be particularly robust.)
Seeing this, we will now parameterize the smoking effects separately for each category, although we will begin by constraining the smoking effects on third and fourth age categories to be equivalent:

```
constraint 1 smokes#3.agecat = smokes#4.agecat
poisson deaths c.smokes#agecat i.agecat, exposure(pyears) irr constraints(1)
```

Iteration 0:  log likelihood = -31.95424
Iteration 1:  log likelihood = -27.796801
Iteration 2:  log likelihood = -27.574177
Iteration 3:  log likelihood = -27.572645
Iteration 4:  log likelihood = -27.572645

_estat gof_

Deviance goodness-of-fit = .0773491
Prob > chi2(1) = 0.7809
Pearson goodness-of-fit = .0773885
Prob > chi2(1) = 0.7809

The goodness-of-fit is now small; we are no longer running roughshod over the data. Let us now consider simplifying the model. The point estimate of the incidence-rate ratio for smoking in age category 1 is much larger than that for smoking in age category 2, but the confidence interval for smokes#1.agecat is similarly wide. Is the difference real?

```
.test smokes#1.agecat = smokes#2.agecat
```

( 1)  [deaths]1b.agecat#c.smokes - [deaths]2.agecat#c.smokes = 0

Chi2(  1) = 1.56
Prob > chi2 = 0.2117

The point estimates of the incidence-rate ratio for smoking in the 35–44 age category is much larger than that for smoking in the 45–54 age category, but there is insufficient data, and we may be observing random differences. With that success, might we also combine the smokers in the third and fourth categories with those in the first and second categories?
. test smokes#2.agecat = smokes#3.agecat, accum
   ( 1) [deaths]1b.agecat#c.smokes - [deaths]2.agecat#c.smokes = 0
   ( 2) [deaths]2.agecat#c.smokes - [deaths]3.agecat#c.smokes = 0
   chi2( 2) = 4.73
   Prob > chi2 = 0.0938

Combining the first four categories may be overdoing it—the 9.38% significance level is enough to stop us, although others may disagree.

Thus we now fit our final model:

. constraint 2 smokes#1.agecat = smokes#2.agecat
. poisson deaths c.smokes#agecat i.agecat, exposure(pyears) irr constraints(1/2)
Iteration 0:  log likelihood = -31.550722
Iteration 1:  log likelihood = -28.525057
Iteration 2:  log likelihood = -28.514535
Iteration 3:  log likelihood = -28.514535
Poisson regression                              Number of obs   =       10
Log likelihood = -28.514535                   Wald chi2(7)    =   642.25
                                                           Prob > chi2    =     0.0000
( 1) [deaths]3.agecat#c.smokes - [deaths]4.agecat#c.smokes = 0
( 2) [deaths]1b.agecat#c.smokes - [deaths]2.agecat#c.smokes = 0

| 45-54  | 4.294559  | .8385329  | 7.46  | 0.000| 2.928987 6.296797    |
| 55-64  | 23.42263  | 7.787716  | 9.49  | 0.000| 12.20738 44.94164    |
| 65-74  | 48.26309  | 16.06939  | 11.64 | 0.000| 25.13068 92.68856    |
| 75-84  | 97.87965  | 34.30881  | 13.08 | 0.000| 49.24123 194.561     |
| _cons  | .0002166  | .0000652  | -28.03| 0.000| .0001201 .0003908    |
| ln(pyears)| 1 (exposure) | | | | |
The above strikes us as a fair representation of the data. The probabilities of observing the deaths seen in these data are estimated using the following `predict` command:

```
. predict p, pr(0, deaths)
. list deaths p
```

<table>
<thead>
<tr>

The probability $Pr(y \leq \text{deaths})$ ranges from 0.23 to 0.80.

### Methods and formulas

In the following, we use the same notation as in [R] `poisson`.

The equation-level scores are given by

$$\text{score}(x/\beta)_j = y_j - e^{\xi_j}$$

The deviance (D) and Pearson (P) goodness-of-fit statistics are given by

$$\ln L_{\text{max}} = \sum_{j=1}^{n} w_j [-y_j \{ \ln(y_j) - 1 \} - \ln(y_j!)]$$

$$\chi^2_D = -2 \{ \ln L - \ln L_{\text{max}} \}$$

$$\chi^2_P = \sum_{j=1}^{n} \frac{w_j (y_j - e^{\xi_j})^2}{e^{\xi_j}}$$

[U] 20 Estimation and postestimation commands
Description

Launch the Postestimation Selector window. The window contains a list of all postestimation features that are available for the currently active estimation results. To launch the dialog box for an item in the list, select an item and click on **Launch**. The list is automatically updated when estimation commands are run or estimates are restored from memory or disk.

Menu

Statistics > Postestimation

Syntax

```
postest
```

Remarks and examples

Stata uses an estimation followed by postestimation analysis paradigm. You type `regress` ... to fit a regression model, then you type `test` ... to test linear relationships among the estimated parameters, or you type `contrast` ... to compare marginal means, or you type `rvfplot` to see a residual-versus-fitted plot, or you type one of a myriad of other postestimation commands. This is an extension of Stata’s “type a little, get a little” concept. The Postestimation Selector exposes this type of postestimation analysis to those who prefer to use the dialog boxes to fit and analyze models, or at least they sometimes prefer the dialogs when exploring their data. We might call this “click a little, get a little”.

The Postestimation Selector knows what is available after any estimation command. It shows the full list of postestimation features that are available after any estimation, and it shows only those that are available. For example, if you fit a linear regression, you can choose from 59 postestimation analyses, including “Likelihood-ratio test comparing models”. If, however, you fit that linear regression using survey estimation, the likelihood-ratio test is not available because that test has no meaning for survey estimation. You will, however, see 8 new postestimation features for survey-data analysis, including “Design and misspecification effects”.

If you are using the menus and dialogs, we recommend you launch the Postestimation Selector and just leave it up—select **Statistics > Postestimation**, or type `postest` at the command line. All available postestimation features for whatever model you are analyzing will then be just a click away.
Here is what the Selector looks like after a logistic regression,
And, here is what it looks like with all the groupings expanded.

[U] 20 Estimation and postestimation commands
predict — Obtain predictions, residuals, etc., after estimation

**Description**

*predict* calculates predictions, residuals, influence statistics, and the like after estimation. Exactly what *predict* can do is determined by the previous estimation command; command-specific options are documented with each estimation command. Regardless of command-specific options, the actions of *predict* share certain similarities across estimation commands:

1. *predict* *newvar* creates *newvar* containing “predicted values”—numbers related to the $E(y_j|x_j)$. For instance, after linear regression, *predict* *newvar* creates $x_j\hat{b}$ and, after probit, creates the probability $\Phi(x_j\hat{b})$.

2. *predict* *newvar*, *xb* creates *newvar* containing $x_j\hat{b}$. This may be the same result as option 1 (for example, linear regression) or different (for example, probit), but regardless, option *xb* is allowed.

3. *predict* *newvar*, *stdp* creates *newvar* containing the standard error of the linear prediction $x_j\hat{b}$.

4. *predict* *newvar*, *other_options* may create *newvar* containing other useful quantities; see help or the reference manual entry for the particular estimation command to find out about other available options.

5. *nooffset* added to any of the above commands requests that the calculation ignore any offset or exposure variable specified by including the *offset(varname)* or *exposure(varname)* option when you fit the model.

*predict* can be used to make in-sample or out-of-sample predictions:

6. *predict* calculates the requested statistic for all possible observations, whether they were used in fitting the model or not. *predict* does this for standard options 1 through 3 and generally does this for estimator-specific options 4.

7. *predict* *newvar* if *e(sample)*, *...* restricts the prediction to the estimation subsample.

8. Some statistics make sense only with respect to the estimation subsample. In such cases, the calculation is automatically restricted to the estimation subsample, and the documentation for the specific option states this. Even so, you can still specify if *e(sample)* if you are uncertain.

9. *predict* can make out-of-sample predictions even using other datasets. In particular, you can

```
. use ds1
. (fit a model)
. use two /* another dataset */
. predict yhat, /* fill in the predictions */
```
Quick start

Create `newvar1` containing the default prediction for the previous estimation command

```
predict newvar1
```

Create `newvar2` containing the linear prediction

```
predict newvar2, xb
```

As above, but only for observations used in the previous estimation

```
predict newvar2 if e(sample), xb
```

Create `newvar3`, the default prediction for the first equation in a multiple-equation model

```
predict newvar3, equation(#1)
```

Same as above when `y1` is the name of the first equation

```
predict newvar3, equation(y1)
```

Note: For a complete list of options available with `predict` after an estimation command, see the corresponding postestimation entry.

Options

<table>
<thead>
<tr>
<th>Main</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xb</td>
<td>calculates the linear prediction from the fitted model. That is, all models can be thought of as estimating a set of parameters $b_1, b_2, \ldots, b_k$, and the linear prediction is $\hat{y}<em>j = b_1 x</em>{1j} + b_2 x_{2j} + \cdots + b_k x_{kj}$, often written in matrix notation as $\hat{y}<em>j = x_j b$. For linear regression, the values $\hat{y}<em>j$ are called the predicted values or, for out-of-sample predictions, the forecast. For logit and probit, for example, $\hat{y}<em>j$ is called the logit or probit index. $x</em>{1j}, x</em>{2j}, \ldots, x</em>{kj}$ are obtained from the data currently in memory and do not necessarily correspond to the data on the independent variables used to fit the model (obtaining $b_1, b_2, \ldots, b_k$).</td>
</tr>
<tr>
<td>stdp</td>
<td>calculates the standard error of the linear prediction. Here the prediction means the same thing as the “index”, namely, $x_j b$. The statistic produced by stdp can be thought of as the standard error of the predicted expected value, or mean index, for the observation’s covariate pattern. The standard error of the prediction is also commonly referred to as the standard error of the fitted value. The calculation can be made in or out of sample.</td>
</tr>
</tbody>
</table>
predict is allowed only after you have previously fit a multiple-equation model. The standard error of
the difference in linear predictions \((x_{1j} b - x_{2j} b)\) between equations 1 and 2 is calculated. This
option requires that \(\text{equation(eqno1, eqno2)}\) be specified.

\textbf{score} calculates the equation-level score, \(\partial \ln L / \partial (x_j \beta)\). Here \(\ln L\) refers to the log-likelihood
function.

\textbf{scores} is the ME model equivalent of the \textbf{score} option, resulting in multiple equation-level score
variables. An equation-level score variable is created for each equation in the model; ancillary
parameters—such as \(\ln \sigma\) and \(\text{atanh} \rho\)—make up separate equations.

\textbf{equation(eqno[, eqno])}—synonym \textbf{outcome()}—is relevant only when you have previously fit a
multiple-equation model. It specifies the equation to which you are referring.

equation() is typically filled in with one \textit{eqno}—it would be filled in that way with options
\textit{xb} and \textit{stdp}, for instance. \textbf{equation(#1)} would mean the calculation is to be made for the
first equation, \textbf{equation(#2)} would mean the second, and so on. You could also refer to the
equations by their names. \textbf{equation(income)} would refer to the equation named income and
\textbf{equation(hours)} to the equation named hours.

If you do not specify \textbf{equation()}, results are the same as if you specified \textbf{equation(#1)}.

Other statistics, such as \textit{stddp}, refer to between-equation concepts. In those cases, you might
specify \textbf{equation(#1,#2)} or \textbf{equation(income,hours)}. When two equations must be specified,
\textbf{equation()} is required.

\textbf{nooffset} may be combined with most statistics and specifies that the calculation should be made,
ignoring any offset or exposure variable specified when the model was fit.

This option is available, even if it is not documented for \textit{predict} after a specific command. If
neither the \textit{offset(varname_o)} option nor the \textit{exposure(varname_e)} option was specified when
the model was fit, specifying \textit{nooffset} does nothing.

\textit{other_options} refers to command-specific options that are documented with each command.

**Remarks and examples**

Remarks are presented under the following headings:

- Estimation-sample predictions
- Out-of-sample predictions
- Residuals
- Single-equation (SE) models
- SE model scores
- Multiple-equation (ME) models
- ME model scores

Most of the examples are presented using linear regression, but the general syntax is applicable
to all estimators.

You can think of any estimation command as estimating a set of coefficients \(b_1, b_2, \ldots, b_k\)
corresponding to the variables \(x_1, x_2, \ldots, x_k\), along with a (possibly empty) set of ancillary statistics
\(\gamma_1, \gamma_2, \ldots, \gamma_m\). All estimation commands store the \(b_i\)s and \(\gamma_i\)s. \textit{predict} accesses that stored
information and combines it with the data currently in memory to make various calculations. For
instance, \textit{predict} can calculate the linear prediction, \(\hat{y}_{ij} = b_1 x_{1ij} + b_2 x_{2ij} + \cdots + b_k x_{kij}\). The data
on which \textit{predict} makes the calculation can be the same data used to fit the model or a different
predict — Obtain predictions, residuals, etc., after estimation

dataset—it does not matter. predict uses the stored parameter estimates from the model, obtains the corresponding values of \( x \) for each observation in the data, and then combines them to produce the desired result.

Estimation-sample predictions

Example 1

We have a 74-observation dataset on automobiles, including the mileage rating (\( mpg \)), the car’s weight (\( weight \)), and whether the car is foreign (\( foreign \)). We fit the model

```
. use http://www.stata-press.com/data/r14/auto
(1978 Automobile Data)
. regress mpg weight if foreign
```

```
Source | SS df MS
---------+--------------------------------------------------
Model    | 427.990298 1 427.990298
Residual | 489.873338 20 24.4936669
---------+--------------------------------------------------
Total    | 917.863636 21 43.7077922

Number of obs = 22
F(1, 20) = 17.47
Prob > F = 0.0005
R-squared = 0.4663
Adj R-squared = 0.4396
Root MSE = 4.9491

mpg | Coef. Std. Err. t P>|t| [95% Conf. Interval]
-----+-------------------------------------------------------------
weight | -.010426 .0024942 -4.18 0.000 -.0156287 -.0052232
_cons  | 48.9183 5.871851 8.33 0.000 36.66983 61.16676
```

If we were to type `predict pmpg` now, we would obtain the linear predictions for all 74 observations. To obtain the predictions just for the sample on which we fit the model, we could type

```
. predict pmpg if e(sample)
(option xb assumed; fitted values)
(52 missing values generated)
```

Here `e(sample)` is true only for foreign cars because we typed `if foreign` when we fit the model and because there are no missing values among the relevant variables. If there had been missing values, `e(sample)` would also account for those.

By the way, the `if e(sample)` restriction can be used with any Stata command, so we could obtain summary statistics on the estimation sample by typing

```
. summarize if e(sample)
(output omitted)
```

Out-of-sample predictions

By out-of-sample predictions, we mean predictions extending beyond the estimation sample. In the example above, typing `predict pmpg` would generate linear predictions using all 74 observations.

predict will work on other datasets, too. You can use a new dataset and type `predict` to obtain results for that sample.
Example 2

Using the same auto dataset, assume that we wish to fit the model

\[ \text{mpg} = \beta_1 \text{weight} + \beta_2 \ln(\text{weight}) + \beta_3 \text{foreign} + \beta_4 \]

We first create the \( \ln(\text{weight}) \) variable, and then type the `regress` command:

```
. use http://www.stata-press.com/data/r14/auto, clear
(1978 Automobile Data)
. generate lnweight = ln(weight)
. regress mpg weight lnweight foreign
```

If we typed `predict pmpg` now, we would obtain predictions for all 74 cars in the current data. Instead, we are going to use a new dataset.

The dataset `newautos.dta` contains the make, weight, and place of manufacture of two cars, the Pontiac Sunbird and the Volvo 260. Let’s use the dataset and create the predictions:

```
. use http://www.stata-press.com/data/r14/newautos, clear
(New Automobile Models)
. list

<table>
<thead>
<tr>
<th>make</th>
<th>weight</th>
<th>foreign</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pont. Sunbird</td>
<td>2690</td>
<td>Domestic</td>
</tr>
<tr>
<td>Volvo 260</td>
<td>3170</td>
<td>Foreign</td>
</tr>
</tbody>
</table>
```

```
. predict mpg
(option xb assumed; fitted values)
variable lnweight not found
r(111);
```

Things did not work. We typed `predict mpg`, and Stata responded with the message “variable lnweight not found”. `predict` can calculate predicted values on a different dataset only if that dataset contains the variables that went into the model. Here our dataset does not contain a variable called `lnweight`. `lnweight` is just the log of weight, so we can create it and try again:
We obtained our predicted values. The Pontiac Sunbird has a predicted mileage rating of 23.3 mpg, whereas the Volvo 260 has a predicted rating of 17.9 mpg.

Residuals

Example 3

With many estimators, predict can calculate more than predicted values. With most regression-type estimators, we can, for instance, obtain residuals. Using our regression example, we return to our original data and obtain residuals by typing

```
. use http://www.stata-press.com/data/r14/auto, clear
(1978 Automobile Data)
. generate lnweight = ln(weight)
. regress mpg weight lnweight foreign
(output omitted)
. predict double resid, residuals
. summarize resid
```

```
<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>resid</td>
<td>74</td>
<td>-1.31e-14</td>
<td>3.212091</td>
<td>-5.453078</td>
<td>13.83719</td>
</tr>
</tbody>
</table>
```

We could do this without refitting the model. Stata always remembers the last set of estimates, even as we use new datasets.

It was not necessary to type the double in `predict double resid, residuals`, but we wanted to remind you that you can specify the type of a variable in front of the variable’s name; see [U] 11.4.2 Lists of new variables. We made the new variable `resid` a double rather than the default float.

If you want your residuals to have a mean as close to zero as possible, remember to request the extra precision of double. If we had not specified `double`, the mean of `resid` would have been roughly $10^{-9}$ rather than $10^{-14}$. Although $10^{-14}$ sounds more precise than $10^{-9}$, the difference really does not matter.

For linear regression, predict can also calculate standardized residuals and Studentized residuals with the options `rstandard` and `rstudent`; for examples, see [R] regress postestimation.
Single-equation (SE) models

If you have not read the discussion above on using `predict` after linear regression, please do so. And `predict`’s default calculation almost always produces a statistic in the same metric as the dependent variable of the fitted model—for example, predicted counts for Poisson regression. In any case, `xb` can always be specified to obtain the linear prediction.

`predict` can calculate the standard error of the prediction, which is obtained by using the covariance matrix of the estimators.

Example 4

After most binary outcome models (for example, `logistic`, `logit`, `probit`, `cloglog`, `scobit`), `predict` calculates the probability of a positive outcome if we do not tell it otherwise. We can specify the `xb` option if we want the linear prediction (also known as the logit or probit index). The odd abbreviation `xb` is meant to suggest $x \beta$. In logit and probit models, for example, the predicted probability is $p = F(x \beta)$, where $F()$ is the logistic or normal cumulative distribution function, respectively.

```
. logistic foreign mpg weight
(output omitted)
. predict phat
(option pr assumed; Pr(foreign))
. predict idxhat, xb
. summarize foreign phat idxhat
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign</td>
<td>74</td>
<td>.2972973</td>
<td>.4601885</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>phat</td>
<td>74</td>
<td>.2972973</td>
<td>.3052979</td>
<td>.000729</td>
<td>.8980594</td>
</tr>
<tr>
<td>idxhat</td>
<td>74</td>
<td>-1.678202</td>
<td>2.321509</td>
<td>-7.223107</td>
<td>2.175845</td>
</tr>
</tbody>
</table>
```

Because this is a logit model, we could obtain the predicted probabilities ourselves from the predicted index

```
. generate phat2 = exp(idxhat)/(1+exp(idxhat))
```

but using `predict` without options is easier.

Example 5

For all models, `predict` attempts to produce a predicted value in the same metric as the dependent variable of the model. We have seen that for dichotomous outcome models, the default statistic produced by `predict` is the probability of a success. Similarly, for Poisson regression, the default statistic produced by `predict` is the predicted count for the dependent variable. You can always specify the `xb` option to obtain the linear combination of the coefficients with an observation’s $x$ values (the inner product of the coefficients and $x$ values). For `poisson` (without an explicit exposure), this is the natural log of the count.

```
. use http://www.stata-press.com/data/r14/airline, clear
. poisson injuries XYZowned
(output omitted)
```
predict — Obtain predictions, residuals, etc., after estimation

predict injhat
(option n assumed; predicted number of events)
predict idx, xb

generate exp_idx = exp(idx)

summarize injuries injhat exp_idx idx

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>injuries</td>
<td>9</td>
<td>7.11111</td>
<td>5.487359</td>
<td>1</td>
<td>19</td>
</tr>
<tr>
<td>injhat</td>
<td>9</td>
<td>7.11111</td>

<td>9</td>
<td>1.95517</td>
<td>.1225612</td>
<td>1.791759</td>
<td>2.036882</td>
</tr>
</tbody>
</table>

We note that our “hand-computed” prediction of the count (exp_idx) matches what was produced by the default operation of predict.

If our model has an exposure-time variable, we can use predict to obtain the linear prediction with or without the exposure. Let’s verify what we are getting by obtaining the linear prediction with and without exposure, transforming these predictions to count predictions and comparing them with the default count prediction from predict. We must remember to multiply by the exposure time when using predict ...

use http://www.stata-press.com/data/r14/airline, clear
poisson injuries XYZowned, exposure(n)
(output omitted)
predict double injhat
(option n assumed; predicted number of events)
predict double idx, xb

generate double exp_idx = exp(idx)
predict double idxn, xb nooffset

generate double exp_idxn = exp(idxn)*n

summarize injuries injhat exp_idx exp_idxn idx idxn

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>injuries</td>
<td>9</td>
<td>7.11111</td>
<td>5.487359</td>
<td>1</td>
<td>19</td>
</tr>
<tr>
<td>injhat</td>
<td>9</td>
<td>7.11111</td>
<td>3.10936</td>
<td>2.919621</td>
<td>12.06158</td>
</tr>
<tr>
<td>exp_idx</td>
<td>9</td>
<td>7.11111</td>
<td>3.10936</td>
<td>2.919621</td>
<td>12.06158</td>
</tr>
<tr>
<td>exp_idxn</td>
<td>9</td>
<td>7.11111</td>
<td>3.10936</td>
<td>2.919621</td>
<td>12.06158</td>
</tr>
<tr>
<td>idx</td>
<td>9</td>
<td>1.869722</td>
<td>.4671044</td>
<td>1.071454</td>
<td>2.490025</td>
</tr>
<tr>
<td>idxn</td>
<td>9</td>
<td>4.18814</td>
<td>.1904042</td>
<td>4.061204</td>
<td>4.442013</td>
</tr>
</tbody>
</table>

Looking at the identical means and standard deviations for injhat, exp_idx, and exp_idxn, we see that we can reproduce the default computations of predict for poisson estimations. We have also demonstrated the relationship between the count predictions and the linear predictions with and without exposure.

SE model scores

Example 6

With most maximum likelihood estimators, predict can calculate equation-level scores. The first derivative of the log likelihood with respect to $x_j\beta$ is the equation-level score.
predict — Obtain predictions, residuals, etc., after estimation

. use http://www.stata-press.com/data/r14/auto, clear
(1978 Automobile Data)
. logistic foreign mpg weight
(output omitted)
. predict double sc, score
. summarize sc

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>sc</td>
<td>74</td>
<td>-1.37e-12</td>
<td>0.3533133</td>
<td>-0.8760856</td>
<td>0.8821309</td>
</tr>
</tbody>
</table>

See [P] _robust and [SVY] variance estimation for details regarding the role equation-level scores play in linearization-based variance estimators.

Technical note

predict after some estimation commands, such as regress and cnsreg, allows the score option as a synonym for the residuals option.

Multiple-equation (ME) models

If you have not read the above discussion on using predict after SE models, please do so. With the exception of the ability to select specific equations to predict from, the use of predict after ME models follows almost the same form that it does for SE models.

Example 7

The details of prediction statistics that are specific to particular ME models are documented with the estimation command. If you are using ME commands that do not have separate discussions on obtaining predictions, read Obtaining predicted values in [R] mlogit postestimation, even if your interest is not in multinomial logistic regression. As a general introduction to the ME models, we will demonstrate predict after sureg:

. use http://www.stata-press.com/data/r14/auto, clear
(1978 Automobile Data)
. sureg (price foreign displ) (weight foreign length)

Seemingly unrelated regression

<table>

Sureg estimated two equations, one called price and the other weight; see [R] sureg.

. predict pred_p, equation(price)  
(option xb assumed; fitted values)
. predict pred_w, equation(weight)  
(option xb assumed; fitted values)
. summarize price pred_p weight pred_w

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>price</td>
<td>74</td>
<td>6165.257</td>
<td>2949.496</td>
<td>3291</td>
<td>15906</td>
</tr>
<tr>
<td>pred_p</td>
<td>74</td>
<td>6165.257</td>
<td>1678.805</td>
<td>2664.81</td>
<td>10485.33</td>
</tr>
<tr>
<td>weight</td>
<td>74</td>
<td>3019.459</td>
<td>777.1936</td>
<td>1760</td>
<td>4840</td>
</tr>
<tr>
<td>pred_w</td>
<td>74</td>
<td>3019.459</td>
<td>726.0468</td>
<td>1501.602</td>
<td>4447.996</td>
</tr>
</tbody>
</table>

You may specify the equation by name, as we did above, or by number: equation(#1) means the same thing as equation(price) in this case.

**ME model scores**

▶ Example 8

For ME models, predict allows you to specify a stub when generating equation-level score variables. predict generates new variables using this stub by appending an equation index. Depending upon the command, the index will start with 0 or 1. Here is an example where predict starts indexing the score variables with 0.

. ologit rep78 mpg weight
(output omitted)
. predict double sc*, scores
. summarize sc*

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>sc0</td>
<td>69</td>
<td>-1.33e-11</td>
<td>.5337363</td>
<td>-.9854088</td>
<td>.921433</td>
</tr>
<tr>
<td>sc1</td>
<td>69</td>
<td>-7.69e-13</td>
<td>.186919</td>
<td>-.2738537</td>
<td>.9854088</td>
</tr>
<tr>
<td>sc2</td>
<td>69</td>
<td>-2.87e-11</td>
<td>.4061637</td>
<td>-.5188487</td>
<td>1.130178</td>
</tr>
<tr>
<td>sc3</td>
<td>69</td>
<td>-1.04e-10</td>
<td>.5315368</td>

</tr>
</tbody>
</table>
Methods and formulas

Denote the previously estimated coefficient vector as $\mathbf{b}$ and its estimated variance matrix as $\mathbf{V}$. `predict` works by recalling various aspects of the model, such as $\mathbf{b}$, and combining that information with the data currently in memory. Let’s write $\mathbf{x}_j$ for the $j$th observation currently in memory.

The predicted value (xb option) is defined as $\hat{y}_j = \mathbf{x}_j \mathbf{b} + \text{offset}_j$

The standard error of the prediction (the stdp option) is defined as $s_{p,j} = \sqrt{\mathbf{x}_j \mathbf{V} \mathbf{x}_j'}$

The standard error of the difference in linear predictions between equations 1 and 2 is defined as

$$s_{dp,j} = \{(x_{1j}, -x_{2j}, 0, \ldots, 0) \mathbf{V} (x_{1j}, -x_{2j}, 0, \ldots, 0)' \}^{\frac{1}{2}}$$

See the individual estimation commands for information about calculating command-specific `predict` statistics.

Also see

[R] `predictnl` — Obtain nonlinear predictions, standard errors, etc., after estimation
[P] `_predict` — Obtain predictions, residuals, etc., after estimation programming command
[U] 20 Estimation and postestimation commands
predictnl — Obtain nonlinear predictions, standard errors, etc., after estimation

Description

predictnl calculates (possibly) nonlinear predictions after any Stata estimation command and optionally calculates the variances, standard errors, Wald test statistics, significance levels, and confidence limits for these predictions. Unlike its companion nonlinear postestimation commands testnl and nlcom, predictnl generates functions of the data (that is, predictions), not scalars. The quantities generated by predictnl are thus vectorized over the observations in the data.

Consider some general prediction, \( g(\theta, x_i) \), for \( i = 1, \ldots, n \), where \( \theta \) are the model parameters and \( x_i \) are some data for the \( i \)th observation; \( x_i \) is assumed fixed. Typically, \( g(\theta, x_i) \) is estimated by \( \hat{g}(\hat{\theta}, x_i) \), where \( \hat{\theta} \) are the estimated model parameters, which are stored in \textit{e(b)} following any Stata estimation command.

In its most common use, predictnl generates two variables: one containing the estimated prediction, \( \hat{g}(\hat{\theta}, x_i) \), the other containing the estimated standard error of \( g(\hat{\theta}, x_i) \). The calculation of standard errors (and other obtainable quantities that are based on the standard errors, such as test statistics) is based on the delta method, an approximation appropriate in large samples; see Methods and formulas.

predictnl can be used with \textit{svy} estimation results (assuming that \textit{predict} is also allowed), see [SVY] svy postestimation.

The specification of \( g(\hat{\theta}, x_i) \) is handled by specifying \textit{pnl\_exp}, and the values of \( g(\hat{\theta}, x_i) \) are stored in the new variable \textit{newvar} of storage type \textit{type}. \textit{pnl\_exp} is any valid Stata expression and may also contain calls to two special functions unique to predictnl:

1. \textit{predict([predict\_options])}: When you are evaluating \textit{pnl\_exp}, \textit{predict()} is a convenience function that replicates the calculation performed by the command

\[
\text{predict ..., predict\_options}
\]

As such, the \textit{predict()} function may be used either as a shorthand for the formula used to make this prediction or when the formula is not readily available. When used without arguments, \textit{predict()} replicates the default prediction for that particular estimation command.

2. \textit{xb([eqno])}: The \textit{xb()} function replicates the calculation of the linear predictor \( x_i b \) for equation \textit{eqno}. If \textit{xb()} is specified without \textit{eqno}, the linear predictor for the first equation (or the only equation in single-equation estimation) is obtained.

For example, \textit{xb(#1)} (or equivalently, \textit{xb()} with no arguments) translates to the linear predictor for the first equation, \textit{xb(#2)} for the second, and so on. You could also refer to the equations by their names, such as \textit{xb(income)}.

When specifying \textit{pnl\_exp}, both of these functions may be used repeatedly, in combination, and in combination with other Stata functions and expressions. See Remarks and examples for examples that use both of these functions.
Quick start

After `regress`, create `yhat` containing the default linear prediction
   \[ \text{predictnl } yhat = \text{predict()} \]

After `probit y x1 x2`, create `pr1` containing predicted probability that \( y = 1 \)
   \[ \text{predictnl } pr1 = \text{predict(pr)} \]

As above, and create `lb1` and `ub1` containing the upper and lower bounds of the 95% confidence interval for the prediction
   \[ \text{predictnl } pr1 = \text{predict(pr)}, \text{ci(lb1 ub1)} \]

Same as above, specified as a function of the linear prediction
   \[ \text{predictnl } pr1 = \text{normal(xb())}, \text{ci(lb1 ub1)} \]

Same as above, specified as a function of the coefficients
   \[ \text{predictnl } pr1 = \text{normal(_b[_cons]+_b[x1]*x1+_b[x2]*x2)}, \text{ci(lb1 ub1)} \]

As above, but create the prediction using \( x1 \) equal to 0
   \[ \text{predictnl } pr1 = \text{normal(_b[_cons]+_b[x1]*0+_b[x2]*x2)}, \text{ci(lb1 ub1)} \]

As above, but create variable `se1` containing the standard error of the prediction
   \[ \text{predictnl } pr1 = \text{normal(_b[_cons]+_b[x1]*0+_b[x2]*x2)}, \text{se(se1)} \]

After a multiple-equation model, create `ratio` as the ratio of the linear predictions from the second and third equations
   \[ \text{predictnl ratio = xb(#2)/xb(#3)} \]
Syntax

```
predictnl [type] newvar = pnl_exp [if] [in] [ , options]
```

**Options**

**Main**

- `se(newvar)` adds *newvar* of storage type *type*, where for each *i* in the prediction sample, *newvar[i]* contains the estimated standard error of $g(\hat{\theta}, x_i)$.
- `variance(newvar)` adds *newvar* of storage type *type*, where for each *i* in the prediction sample, *newvar[i]* contains the estimated variance of $g(\hat{\theta}, x_i)$.
- `wald(newvar)` adds *newvar* of storage type *type*, where for each *i* in the prediction sample, *newvar[i]* contains the Wald test statistic for the test of the hypothesis $H_0: g(\theta, x_i) = 0$.
- `p(newvar)` adds *newvar* of storage type *type*, where *newvar[i]* contains the significance level (p-value) of the Wald test of $H_0: g(\theta, x_i) = 0$ versus the two-sided alternative.
- `ci(newvars)` requires the specification of two *newvars*, such that the *i*th observation of each will contain the left and right endpoints (respectively) of a confidence interval for $g(\theta, x_i)$. The level of the confidence intervals is determined by `level(#)`.
- `level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.7 Specifying the width of confidence intervals.
- `g(stub)` specifies that new variables, *stub1*, *stub2*, ..., *stubk* be created, where *k* is the dimension of $\theta$. *stub1* will contain the observation-specific derivatives of $g(\theta, x_i)$ with respect to the first element, $\theta_1$, of $\theta$; *stub2* will contain the derivatives of $g(\theta, x_i)$ with respect to $\theta_2$, etc.; If the derivative of $g(\theta, x_i)$ with respect to a particular coefficient in $\theta$ equals zero for all observations in the prediction sample, the *stub* variable for that coefficient is not created. The ordering of the parameters in $\theta$ is precisely that of the stored vector of parameter estimates $e(b)$. 
iterate(#) specifies the maximum number of iterations used to find the optimal step size in the
calculation of numerical derivatives of $g(\theta, x_i)$ with respect to $\theta$. By default, the maximum number
of iterations is 100, but convergence is usually achieved after only a few iterations. You should
rarely have to use this option.

force forces the calculation of standard errors and other inference-related quantities in situations
where predictnl would otherwise refuse to do so. The calculation of standard errors takes place
by evaluating (at $\hat{\theta}$) the numerical derivative of $g(\theta, x_i)$ with respect to $\theta$. If predictnl detects
that $g()$ is possibly a function of random quantities other than $\hat{\theta}$, it will refuse to calculate standard
errors or any other quantity derived from them. The force option forces the calculation to take
place anyway. If you use the force option, there is no guarantee that any inference quantities (for
example, standard errors) will be correct or that the values obtained can be interpreted.

The following option is available with predictnl but is not shown in the dialog box:
df(#) specifies that the $F$ distribution with # denominator degrees of freedom be used for the
reference distribution of the test statistic.

Remarks and examples

Remarks are presented under the following headings:

- Introduction
- Nonlinear transformations and standard errors
- Using xb() and predict()
- Multiple-equation (ME) estimators
- Test statistics and significance levels
- Manipulability
- Confidence intervals

Introduction

predictnl and nlcom both use the delta method. They take a nonlinear transformation of the
estimated parameter vector from some fitted model and apply the delta method to calculate the
variance, standard error, Wald test statistic, etc., of this transformation. nlcom is designed for scalar
functions of the parameters, and predictnl is designed for functions of the parameters and of the
data, that is, for predictions.

Nonlinear transformations and standard errors

We begin by fitting a probit model to the low-birthweight data of Hosmer, Lemeshow, and
Sturdivant (2013, 24). The data are described in detail in example 1 of [R] logistic.
. use http://www.stata-press.com/data/r14/lbw

After we fit such a model, we first would want to generate the predicted probabilities of a low birthweight, given the covariate values in the estimation sample. This is easily done using predict after probit, but it doesn’t answer the question, “What are the standard errors of those predictions?”

For the time being, we will consider ourselves ignorant of any automated way to obtain the predicted probabilities after probit. The formula for the prediction is

\[ \Pr(y \neq 0|x_i) = \Phi(x_i \beta) \]

where \( \Phi \) is the standard cumulative normal. Thus for this example, \( g(\theta, x_i) = \Phi(x_i \beta) \). Armed with the formula, we can use predictnl to generate the predictions and their standard errors:

. predictnl phat = normal(_b[_cons] + _b[ht]*ht + _b[ptl]*ptl + _b[smoke]*smoke + _b[lwt]*lwt), se(phat_se)
. list phat phat_se lwt smoke ptl ht in -10/1

</tbody>
</table>

Thus subject 180 in our data has an estimated probability of low birthweight of 23.6% with standard error 4.3%.

Used without options, predictnl is not much different from generate. By specifying the se(phat_se) option, we were able to obtain a variable containing the standard errors of the predictions; therein lies the utility of predictnl.
Using \texttt{xb()} and \texttt{predict()}

As was the case above, a prediction is often not a function of a few isolated parameters and their corresponding variables but instead is some (possibly elaborate) function of the entire linear predictor. For models with many predictors, the brute-force expression for the linear predictor can be cumbersome to type. An alternative is to use the inline function \texttt{xb()}. \texttt{xb()} is a shortcut for having to type \(_b[_cons] + _b[ht]*ht + _b[ptl]*ptl + \ldots\),

\begin{verbatim}
. drop phat phat_se
. predictnl phat = norm(xb()), se(phat_se)
. list phat phat_se lwt smoke ptl ht in -10/l
\end{verbatim}

\begin{verbatim}
<p>| | | | | | |</p>
<table>

<td>101</td>
<td>smoker</td>
<td>1 0</td>
</tr>
<tr>
<td>185</td>
<td>0.4477045</td>
<td>.079889</td>
<td>95</td>
<td>smoker</td>
<td>0 0</td>
</tr>
<tr>
<td>186</td>
<td>0.2988379</td>
<td>.0576306</td>
<td>100</td>
<td>nonsmoker</td>
<td>0 0</td>
</tr>
<tr>
<td>187</td>
<td>0.4514706</td>
<td>.080815</td>
<td>94</td>
<td>smoker</td>
<td>0 0</td>
</tr>
<tr>
<td>188</td>
<td>0.5615571</td>
<td>.1551051</td>
<td>142</td>
<td>nonsmoker</td>
<td>0 1</td>
</tr>
<tr>
<td>189</td>
<td>0.7316517</td>
<td>.1361469</td>
<td>130</td>
<td>smoker</td>
<td>0 1</td>
</tr>
</tbody>
</table>
\end{verbatim}

which yields the same results. This approach is easier, produces more readable code, and is less prone to error, such as forgetting to include a term in the sum.

Here we used \texttt{xb()} without arguments because we have only one equation in our model. In multiple-equation (ME) settings, \texttt{xb()} (or equivalently \texttt{xb(#1)}) yields the linear predictor from the first equation, \texttt{xb(#2)} from the second, etc. You can also refer to equations by their names, for example, \texttt{xb(income)}.

\section*{Technical note}

Most estimation commands in Stata allow the postestimation calculation of linear predictors and their standard errors via \texttt{predict}. For example, to obtain these for the first (or only) equation in the model, you could type

\begin{verbatim}
predict xbvar, xb
predict stdpvar, stdp
\end{verbatim}

Equivalently, you could type

\begin{verbatim}
predictnl xbvar = xb(), se(stdpvar)
\end{verbatim}

but we recommend the first method, as it is faster. As we demonstrated above, however, \texttt{predictnl} is more general.

Returning to our \texttt{probit} example, we can further simplify the calculation by using the inline function \texttt{predict()}. \texttt{predict(pred_options)} works by substituting, within our \texttt{predictnl} expression, the calculation performed by

\begin{verbatim}
predict ..., pred_options
\end{verbatim}
In our example, we are interested in the predicted probabilities after a probit regression, normally obtained via

\[
\text{predict ..., p}
\]

We can obtain these predictions (and standard errors) by using

\[
. \text{drop phat phat_se}
. \text{predictnl phat = predict(p), se(phat_se)}
. \text{list phat phat_se lwt smoke ptl ht in -10/l}
\]
