**intro 7** — Postestimation tests and predictions

Description Remarks and examples Reference Also see

# Description

After fitting a model with sem or gsem, you can perform statistical tests, obtain predicted values, and more. Everything you can do is listed below.

sem and gsem vary in the tests and features available after estimation, and we mark whether each test and feature is available after sem, gsem, or both.

## Remarks and examples

stata.com

Remarks are presented under the following headings:

Replaying the model (sem and gsem)

Displaying odds ratios, incidence-rate ratios, etc. (gsem only)

Obtaining goodness-of-fit statistics (sem and gsem)

Performing tests for including omitted paths and relaxing constraints (sem only)

Performing tests of model simplification (sem and gsem)

Displaying other results, statistics, and tests (sem and gsem)

Obtaining predicted values (sem)

Obtaining predicted values (gsem)

Using contrast, pwcompare, and margins (sem and gsem)

Accessing stored results

## Replaying the model (sem and gsem)

After estimation, you can type sem or gsem without arguments to display the estimation output:

. sem (original output reappears)

If you wish to see results in the Bentler-Weeks formulation, after sem estimation type

. estat framework
 (output omitted)

See [SEM] example 11.

In many of the postestimation commands listed below for use after sem and gsem, you will need to refer symbolically to particular coefficients. For instance, in the model

```
. sem ... (Y < -x1) ..., ... cov(e.Y1 * e.Y2)
```

the symbolic name of the coefficient corresponding to the path Y<-x1 is \_b[Y1:x1], and the symbolic name of the coefficient corresponding to the covariance of e.Y1 and e.Y2 is \_b[cov(e.Y1,e.Y2):\_cons].

Figuring out what the names are can be difficult, so instead, type

. sem, coeflegend

or

. gsem, coeflegend

With this command, sem (gsem) will produce a table looking very much like the estimation output that lists the \_b[] notation for the estimated parameters in the model; see [SEM] example 8.

### Displaying odds ratios, incidence-rate ratios, etc. (gsem only)

In some generalized linear response functions, exponentiated coefficients have a special meaning. Those special meanings are

Common name	Family	Link	Meaning of exp(coef)
logit	Bernoulli	logit	odds ratio
ologit	ordinal	logit	odds ratio
mlogit	multinomial	logit	relative-risk ratio
Poisson	Poisson	log	incidence-rate ratio
nbreg	nbreg	log	incidence-rate ratio

For survival models, the special meanings of the exponentiated coefficients are

Survival distribution	Meaning of exp(coef)		
exponential	hazard ratio		
Weibull	hazard ratio		
gamma	time ratio		
loglogistic	time ratio		
lognormal	time ratio		

gsem reports coefficients, not exponentiated coefficients. You can obtain exponentiated coefficients and their standard errors by using estat eform after estimation. Using estat eform is no different from redisplaying results. The syntax is

estat eform equationname

After gsem, equations are named after the dependent variable, so if you want to see the equation for cases in exponentiated form, you can type estat eform cases.

See [SEM] example 33g, [SEM] example 34g, and [SEM] estat eform.

## Obtaining goodness-of-fit statistics (sem and gsem)

One goodness-of-fit statistic and test is reported at the bottom of the sem output:

Be warned that this test is based on the assumption of joint normality of the observed variables. In the case of nonnormal data, you may specify the vce(sbentler) option to obtain the Satorra-Bentler (1994) scaled  $\chi^2$  test. In either case, the test is a goodness-of-fit test in badness-of-fit units; a significant result implies that the model does not fit well. More mathematically, the null hypothesis of this test is that the fitted covariance matrix and mean vector of the observed variables are equal to the matrix and vector observed in the population as measured by the sample. Remember, however, the goal is not to maximize the goodness of fit. One must not add paths or covariances that are not theoretically meaningful.

In addition, other goodness-of-fit statistics are available:

- 1. (sem only.) Command estat gof reports a variety of goodness-of-fit statistics; see [SEM] example 4.
- 2. (sem only.) Command estat eggof reports  $R^2$ -like goodness-of-fit statistics for each equation separately; see [SEM] example 3.
- 3. (sem only.) Command estat ggof reports goodness-of-fit statistics by group when you have estimated using sem's group() option; see [SEM] example 21.
- 4. (sem only.) Command estat residuals reports the element-by-element differences between the observed and fitted covariance matrix, and the observed and fitted mean vector, optionally in standardized or in normalized units; see [SEM] example 10.
- 5. (sem and gsem.) Command estat ic reports the Akaike and Bayesian information criteria; see [R] estat ic.

### Performing tests for including omitted paths and relaxing constraints (sem only)

- 1. (sem only.) Command estat mindices reports  $\chi^2$  modification indices and significance values for each omitted path in the model, along with the expected parameter change; see [SEM] example 5 and [SEM] example 9.
- 2. (sem only.) Command estat scoretests performs score tests on each of the linear constraints placed on the paths and covariances; see [SEM] example 8.
- 3. (sem only.) Command estat ginvariant is for use when you have estimated using sem's group() option; see [SEM] intro 6. This command tests whether you can relax constraints that parameters are equal across groups; see [SEM] example 22.

## Performing tests of model simplification (sem and gsem)

- 1. (sem and gsem.) Command test reports Wald tests of single or multiple linear constraints. See [SEM] example 8 and [SEM] test.
- 2. (sem and gsem.) Command 1rtest reports likelihood-ratio tests of single or multiple linear constraints. See [SEM] example 10, [SEM] lrtest, and [SEM] example 39g.
- 3. (sem only.) Command estat egtest reports an overall Wald test for each equation in the model, the test corresponding to all coefficients in the equation except the intercept being simultaneously 0; see [SEM] example 13.
- 4. (sem only.) Command estat ginvariant is for use when you have estimated using sem's group() option; see [SEM] intro 6. This command tests whether parameters allowed to vary across groups could be constrained; see [SEM] example 22.

#### Displaying other results, statistics, and tests (sem and gsem)

- (sem only.) The estat stdize: command prefix—used in front of test, testnl, lincom, and nlcom—allows you to perform tests on standardized coefficients. See [SEM] example 16 and [SEM] estat stdize.
- (sem only.) Command estat teffects reports total effects of one variable on another and decomposes the total effect into direct and indirect effects. Results can be reported in standardized or unstandardized form. See [SEM] example 7 and [SEM] estat teffects.
- 3. (sem only.) Command estat stable assesses the stability of nonrecursive structural equation systems; see [SEM] example 7 and [SEM] estat stable.
- 4. (sem and gsem.) Command estat summarize reports summary statistics for the observed variables used in the model; see [SEM] estat summarize.
- 5. (sem and gsem.) Command lincom reports the value, standard error, significance, and confidence interval for linear combinations of estimated parameters; see [SEM] lincom.
- 6. (sem and gsem.) Command nlcom reports the value, standard error, significance, and confidence interval for nonlinear (and linear) combinations of estimated parameters; see [SEM] nlcom and [SEM] example 42g.
- 7. (sem and gsem.) Command estat vce reports the variance—covariance matrix of the estimated parameters; see [R] estat vce.

#### Obtaining predicted values (sem)

You obtain predicted values with the predict command. Below we will write that predictions are the expected values, but be aware that when there are latent variables in your model, predictions are based on predicted scores; the scores can be inconsistent, and thus any prediction based on them can be inconsistent.

#### Available are the following:

- 1. predict newvar, xb(odepvarname) creates new variable newvar containing the predicted values for observed endogenous variable odepvarname.
  - predict *stub\**, xb creates new variables *stub1*, *stub2*, ... containing the predicted values for all the observed endogenous variables in the model.
  - These predicted values are the expected value of the xb given the values of the observed exogenous variables.
- 2. predict newvar, latent(Lname) creates new variable newvar containing the predicted values of the latent variable Lname, whether endogenous or exogenous.
  - predict stub\*, latent creates new variables stub1, stub2, ... containing the predicted values for all the latent variables in the model.
  - Predicted values of latent variables, also known as predicted factor scores, are the expected values of the variables given the values of the observed variables.
- 3. predict newvar, xblatent (Lname) creates new variable newvar containing the predicted values for latent endogenous variable Lname.
  - predict *stub\**, xblatent creates new variables *stub1*, *stub2*, ... containing the predicted values for all the latent endogenous variables in the model.

predict with xblatent(Lname) differs from latent(Lname) in that the factor scores predicted by latent() are then used with the linear equation for Lname to make the prediction.

4. predict stub\*, scores will create a slew of variables, one for each estimated parameter, containing the observation-by-observation values of the first derivative, also known as scores. This command is intended for use by programmers and may only be used after estimation using method(ml) or method(mlmv).

See [SEM] example 14 and [SEM] predict after sem.

### Obtaining predicted values (gsem)

predict after gsem is more complicated than predict after sem because generalized SEMs are more complicated. Two new issues arise: the prediction of generalized linear response variables as opposed to linear response variables, and the optional multilevel nature of the model.

Let's start with the response functions of the observed endogenous variables. Corresponding to predict, xb after sem are the following:

- 1. predict newvar, mu outcome(depvar) predicts mean responses in natural units—linear, probability, counts, and so on. Think  $g^{-1}(x_i b)$  in the generalized linear model notation. Calculations are made using the empirical Bayes mean predictions of latent variables, which can be computationally intensive. You can specify that empirical Bayes modes be used by specifying option conditional(ebmodes).
- 2. predict newvar, mu outcome(depvar) conditional(fixedonly) also predicts mean responses in natural units, and again it is appropriate to think  $g^{-1}(x_ib)$  conditional(fixedonly) includes only the fixed part of the model and is equivalent to setting all latent variables to their mean value, typically 0.
- 3. predict newvar, mu outcome (depvar) marginal also predicts mean responses in natural units, and again it is appropriate to think  $g^{-1}(x_i b)$ . Calculations are made by integrating the prediction formula with respect to the latent variables, which can be computationally intensive.
- 4. Option pr is a synonym for mu when using family-and-link combinations that produce probabilities, such as logit, probit, etc.
- 5. predict newvar, eta outcome (depvar) calculates the linear prediction  $x_ib$ . Calculations are made using the empirical Bayes mean predictions of latent variables, which can be computationally intensive. You can specify that empirical Bayes modes be used by specifying option conditional(ebmodes)
- 6. predict newvar, eta outcome(depvar) conditional(fixedonly) also calculates the linear prediction  $x_i b$ , but includes only the fixed part of the model and is equivalent to setting all latent variables to 0, their mean value.
- 7. predict newvar, density outcome(depvar) calculates the density function for depvar using the current data and model parameters. Calculations are made using the empirical Bayes mean predictions of latent variables, which can be computationally intensive. You can change the treatment of latent variables by specifying option conditional (ebmodes), conditional(fixedonly), or marginal.
- 8. predict newvar, distribution outcome (depvar) calculates the cumulative distribution function for depvar using the current data and model parameters. Calculations are made

using the empirical Bayes mean predictions of latent variables, which can be computationally intensive. You can change the treatment of latent variables by specifying option conditional(ebmodes), conditional(fixedonly), or marginal.

Option distribution is not allowed with family (multinomial).

9. predict newvar, survival outcome (depvar) calculates the cumulative survivor function for depvar using the current data and model parameters. Calculations are made using the empirical Bayes mean predictions of latent variables, which can be computationally intensive. You can change the treatment of latent variables by specifying option conditional(ebmodes), conditional(fixedonly), or marginal.

Option survival is only allowed with family(exponential), family(gamma), family(loglogistic), family(lognormal), and family(weibull).

- 10. Option outcome() varies to accommodate the multiple predictions produced by multinomial logit, ordinal probit, ordinal logit, and ordinal clogclog.
  - a. outcome (depvar #) specifies that you want the prediction for depvar = #.
  - b. outcome (#.depvar) is another way of specifying that you want the prediction for depvar = #.
  - c. outcome (depvar ##) specifies that you want the prediction for the #th category.

For multinomial logit, you use the above form of outcome() when requesting mu or eta predictions.

For ordered outcomes, you use the above form of outcome() when requesting mu predictions. For eta predictions, there is only one linear equation, and you use the usual outcome (depvar) form.

- 11. Some GLM families, such as Poisson, allow specification of an offset or exposure. If you use one of those families and you specify an offset or exposure with gsem when you fit the model and now want predictions with offset = 0 (exposure = 1), you can specify option nooffset.
- 12. To obtain predicted values for all observed endogenous variables, you can omit the outcome() option and replace newvar with stub\*—that is, a piece of a new variable name followed by \*. This is not just convenient; it can also save computer time because some parts of the calculation can be shared.

For example, you can change

```
predict newvar, mu outcome(depvar)
```

to be

```
predict new*, mu
```

So much for the observed endogenous variables. Moving on to latent variables, whether endogenous or exogenous:

- 13. predict newvar, latent (Lname) predicts the value of the specified latent variable by using empirical Bayes means. You can specify that empirical Bayes modes be used by specifying option ebmodes; see item 16b below.
- 14. predict newvar, latent (Lname) se (another\_newvar) will predict both the latent variable and its standard error.

15. You can use the same stub\* trick mentioned for predicting observed endogenous variables to obtain all the latent variables. Replace newvar with stub\* and omit Lname to produce

You can do this with the se() option, too:

```
predict stub*, latent se(another_stub*)
```

- 16. There are four options having to do with the iterative procedure for obtaining the predicted values:
  - a. ebmodes specifies that empirical Bayes modes rather than means be predicted. Because latent variables are assumed to be normally distributed, means and modes are usually similar. They are, however, calculated differently. The predictions are the means or modes of the empirical posterior distributions of the latent variables, which are not necessarily normal. Therefore, the means can differ from the modes. Both are computationally intensive.

The default empirical Bayes means calculation uses adaptive quadrature, which is to say, numerical integration. All three of the options listed below apply to this calculation.

The alternative empirical Bayes mode calculation uses an optimization method that does not require adaptive quadrature. For small datasets, modes can usually be calculated more quickly than means. For large datasets, however, predicting modes can actually take longer. If you specify ebmodes, of the three options listed below, only tolerance() and iterate() are relevant.

b. intpoints(#) specifies the number of quadrature (numerical integration) points to be used to compute the empirical Bayes means. The default is the value used in estimation, which in turn defaults to 7.

This option also controls the number of quadrature points used to compute marginal predictions for the observed endogenous variables.

- c. tolerance(#) specifies the convergence tolerance in computing empirical Bayes means and modes and defaults to the value used in estimation, which in turn defaults to 1.0e-8.
- d. iterate(#) specifies the maximum number of iterations in computing empirical Bayes means and modes and defaults to the value used in estimation, which in turn defaults to 1.001.

That leaves us with only multilevel issues to discuss, and there is only one issue, and it is easy. If you have a multilevel latent variable such as M1[school], you can predict it just as you would any other latent variable:

```
predict newvar, latent(M1[school])
```

If you predict all the latent variables with the stub\* trick, any multilevel latent variables will be automatically included among the new variables.

See [SEM] example 28g, [SEM] example 29g, and [SEM] predict after gsem.

#### Using contrast, pwcompare, and margins (sem and gsem)

constrast, pwcompare, and margins are postestimation commands of Stata. All three can be used after gsem, and margins can be used after sem as well. Even so, these commands work best when you specify your model with Stata's factor-variable notation; see [SEM] intro 3. sem does not allow that notation, and so obtaining desired results is a little more work.

- 1. Command contrast can be used after gsem to test linear hypotheses and make comparisons involving factor variables and their interactions. contrast allows for performing ANOVAstyle tests of main effects, simple effects, or interaction effects. In addition, effects can be decomposed into specific types of contrasts such as comparison against the grand mean, orthogonal polynomial contrasts, and more. See [R] contrast.
- 2. Command pwcompare can be used after gsem to obtain all pairwise comparisons of marginal linear predictions, including cell means, marginal means, etc. See [R] pwcompare.
- 3. Command margins is used after sem or gsem to obtain margins, meaning estimated marginal means, predictive margins, adjusted predictions, and marginal effects. margins also allows for computing contrasts and pairwise comparisons of both linear and nonlinear predictions. See [R] margins, [R] margins, contrast, and [R] margins, pwcompare.

#### Accessing stored results

sem and gsem store all results in e(); see Stored results in [SEM] gsem. To get some idea of what is stored in e() after sem or gsem estimation, type

```
. ereturn list
 (output omitted)
```

You can save estimation results in files or temporarily in memory and do other useful things with them; see [R] estimates.

Not stored by sem in e() are the Bentler-Weeks matrices, but they can be obtained from the r() stored results of estat framework. (The Bentler-Weeks matrices are not relevant in the case of gsem.)

See [SEM] sem and [SEM] estat framework.
