## Frequentist Analysis

- Estimates unknown fixed parameters.
- The data come from a random sample (hypothetical repeatable).
- Uses data to estimate unknown fixed parameters.
- Data expected to satisfy the assumptions for the specified model.

"Conclusions are based on the distribution of statistics derived from random samples, assuming unknown but fixed parameters."

## Bayesian Analysis

- Probability distributions for unknown random parameters.
- The data are fixed.
- Combines data with prior beliefs to get updated probability distributions for the parameters.
- Posterior distribution is used to make explicit probabilistic statements.

"Bayesian analysis answers questions based on the distribution of parameters conditional on the observed sample."

Stata's convenient syntax: `bayes:`

```
regress y x1 x2 x3
```

```
bayes: regress y x1 x2 x3
```

```
logit y x1 x2 x3
```

```

# The method

# The method

- Inverse law of probability (Bayes' Theorem):

$$p(\theta|y) = \frac{p(y|\theta)p(\theta)}{p(y)} = \frac{f(y; \theta)\pi(\theta)}{f(y)}$$

Where:

$f(y; \theta)$ : probability density function for  $y$  given  $\theta$ .

$\pi(\theta)$ : prior distribution for  $\theta$

- The marginal distribution of  $y$ ,  $f(y)$ , does not depend on  $\theta$ ; then we can write the fundamental equation for Bayesian analysis:

$$p(\theta|y) \propto L(\theta; y)\pi(\theta)$$

Where:

$L(\theta; y)$ : likelihood function of the parameters given the data.

## The method

- Let's assume that both the data and the prior beliefs are normally distributed:
  - **The data:**  $y \sim N(\theta, \sigma_d^2)$
  - **The prior:**  $\theta \sim N(\mu_p, \sigma_p^2)$
- **Homework...:** Doing the algebra with the fundamental equation, we find that the posterior distribution would be normal with (see for example Cameron & Trivedi 2005):
  - **The posterior:**  $\theta|y \sim N(\mu, \sigma^2)$

Where:

$$\begin{aligned}\mu &= \sigma^2 (N\bar{y}/\sigma_d^2 + \mu_p/\sigma_p^2) \\ \sigma^2 &= (N/\sigma_d^2 + 1/\sigma_p^2)^{-1}\end{aligned}$$

## The method

- The previous example has a closed form solution.
- What about the cases with non-closed solutions, or more complex distributions?
  - Integration is performed via simulation.
  - We need to use intensive computational simulation tools to find the posterior distribution in most cases.
  - Markov chain Monte Carlo (MCMC) methods are the current standard in most software. Stata implements two alternatives:
    - Metropolis–Hastings (MH) algorithm
    - Gibbs sampling

# The method

- We expect to obtain a stationary sequence when convergence is achieved.

# The method

- An efficient MCMC should have small autocorrelation.
- We expect autocorrelation to become negligible after a few lags.

# The Stata tools for Bayesian regression

## The Stata tools: `bayes:` `bayesmh`

- `bayes:` Convenient syntax for Bayesian regressions
  - Estimation command defines the likelihood for the model.
  - Default priors are assumed to be "weakly informative".
  - Other model specifications are set by default depending on the model defined by the estimation command.
  - Alternative specifications may need to be evaluated.
- `bayesmh` General purpose command for Bayesian analysis
  - You need to specify all the components for the Bayesian regression: likelihood, priors, hyperpriors, blocks, etc.

## Example 1: Probit regression

- Let's look at our first example:

- We have stats on scores, strength of schedule, and bowl game result (win/loss) for the Texas A&M University football team.
- We fit a probit model for the probability to win the bowl game.
- Let's consider a couple of model specifications for a binary dependent variable, whose values depend on a linear latent variable:

$$win\_bowl^* = \alpha_1 + \beta_{sc\_dif} * score\_dif + \beta_{sos} * sos + \epsilon_1$$

$$win\_bowl^* = \alpha_2 + \beta_{scored} * score\_avg + \beta_{against} * against\_avg + \epsilon_2$$

$$win\_bowl = \begin{cases} 1 & \text{if } win\_bowl^* > 0 \\ 0 & \text{otherwise} \end{cases}$$

Where:

- `win_bowl` : result in the bowl game (winloss).
- `score_dif` : Average score difference during the regular season.
- `sos` : Strength of schedule.
- `score_avg` : Average points scored during the regular season.
- `against_avg` : Average points against during the regular season.

Gibbs sampling

Summary

References

Example 1: `bayesstats ess`

- Let's evaluate the effective sample size.

```
. bayesstats ess
Efficiency summaries      MCMC sample size =      10,000
```

<code>winbowl</code>	ESS	Corr. time	Efficiency
<code>score_dif</code>	761.28	13.14	0.0761
<code>sos</code>	797.34	12.54	0.0797
<code>_cons</code>	650.45	15.37	0.0650

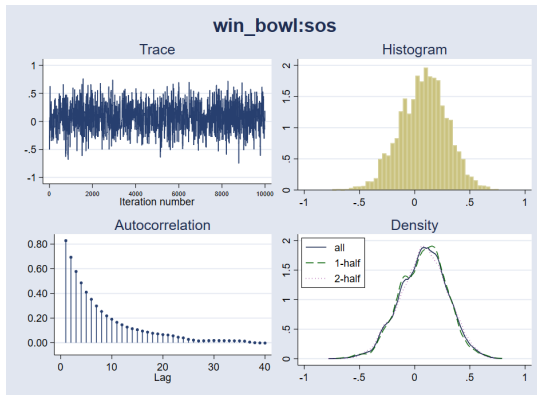

- We expect to have low autocorrelation. Correlation time provides an estimate for the lag after which autocorrelation in an MCMC sample is small.
- Efficiencies over 10% are considered good for MH. Efficiencies under 1% would be a source of concern.

## Example 1: bayesgraph

- We can use `bayesgraph` to look at the trace, the correlation, and the density. For example:

### . bayesgraph diagnostic {sos}

- The trace indicates that convergence was achieved.
- Correlation dies out after around 10 periods.

## Example 1: bayesgraph

- We can use `bayesgraph` to look at the trace, the correlation, and the density. For example:

### . bayesgraph diagnostic {\_cons}

- Correlation dies out after around 15 periods.

Example 1: `bayestest model`

- `bayestest model` is another postestimation command to compare different models.
- `bayestest model` computes the posterior probabilities for each model.
- The result indicates which model is more likely.
- It requires that the models use the same data and that they have proper posterior.
- It can be used to compare models with:
  - Different priors and/or different posterior distributions.
  - Different regression functions.
  - Different covariates.
- MCMC convergence should be verified before comparing the models.

Summary

References

Example 1: `bayestest model`

- Let's fit two other models and compare them with the one we already fit.
- We store the results for the three models, and we use the postestimation command `bayestest model` to select one of them.

```
quietly {
    bayes , rseed(123) saving(dif_sos,replace):    ///
        probit winbowl score_dif sos
    estimates store dif_sos

    bayes , rseed(123) saving(score,replace):    ///
        probit winbowl scored_avg against_avg
    estimates store scored_against

    bayes , rseed(123) saving(srs_linear,replace) ///
        prior({winbowl:srs}, normal(10,20)):    ///
        block({winbowl:srs_cons}):             ///
        regress winbowl srs
    estimates store srs_linear
}
bayestest model dif_sos scored_against srs_linear
```

## Example 1: bayestest model

- Here is the output for bayestest model

```
. quietly {
. bayestest model dif_sos scored_against srs_linear
Bayesian model tests
```

	log(ML)	P (M)	P (M y)
dif_sos	-25.9158	0.3333	0.3679
scored_against	-26.7528	0.3333	0.1593
srs_linear	-25.6652	0.3333	0.4727

**Note:** Marginal likelihood (ML) is computed using Laplace-Metropolis approximation.

- We could also assign different priors for the models:

```
. bayestest model dif_sos scored_against srs_linear, ///
prior(.3 .5 .2)
```

Bayesian model tests

	log(ML)	P (M)	P (M y)
dif_sos	-25.9158	0.3000	0.3879
scored_against	-26.7528	0.5000	0.2799
srs_linear	-25.6652	0.2000	0.3322

**Note:** Marginal likelihood (ML) is computed using Laplace-Metropolis approximation.

## Example 1: bayestest model

- Here is the output for `bayestest model`

```
. quietly {
. bayestest model dif_sos scored_against srs_linear
Bayesian model tests
```

	log(ML)	P (M)	P (M y)
<code>dif_sos</code>	-25.9158	0.3333	0.3679
<code>scored_against</code>	-26.7528	0.3333	0.1593
<code>srs_linear</code>	-25.6652	0.3333	0.4727

Note: Marginal likelihood (ML) is computed using Laplace-Metropolis approximation.

- We could also assign different priors for the models:

## Example 2: Random-effects Poisson model

## Example 2: Random-effects Poisson model

- Let's use `bayes`: to fit a random-effects Poisson model for a count dependent variable.

$$\Pr(y_{it} = y | x_{it}, \alpha_j) = \frac{e^{-\mu_{it}} \mu_{it}^y}{y!}$$

Where:

$$\mu_{i,t} = \exp(x_{i,t}\beta + \alpha_j)$$

$\alpha_j \sim N(0, \sigma_\alpha^2)$  is the individual panel random effect.

- This is also referred to as a two-level random intercept model.
- We can also fit this model with `mepoisson` or `xtpoisson, re normal`.

## Example 2: Random-effects Poisson model

- This time we are going to work with simulated data.
- Here is the code to simulate the panel dataset:

```
clear
set obs 300
set seed 123

*Panel level*
generate id      = _n
generate alpha  = rnormal(0, .33)

*Observation level*
expand 5
bysort id:generate year = _n
xtset id year
generate x1 = rnormal()
generate x2 = runiform()
generate x3 = rnormal()

*Generate dependent variable*

generate y = rpoisson(exp(.1*x1-.1*x2+.1*x3+.75+alpha))
```

## Example 2: bayesgraph diagnostic

- We can look at the diagnostic graph for a couple of variables:

```
. bayesgraph diagnostic {y:x1}
```

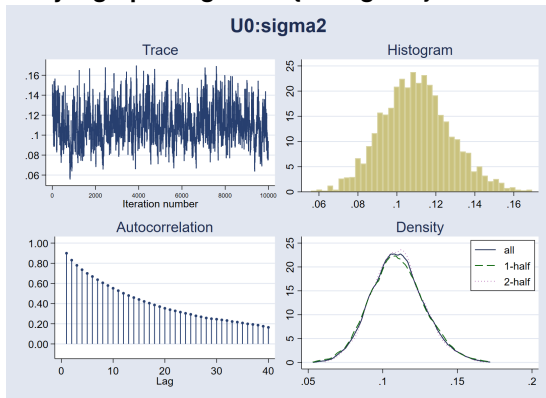

- The trace seems to indicate convergence.
- Autocorrelation becomes negligible after about 15 periods.
- Densities are similar for first and second halves of the MCMC sample.

## Example 2: bayesgraph diagnostic

- We now look at the diagnostic graphs for {U0:sigma2}

### . bayesgraph diagnostic {U0:sigma2}

- The trace seems to indicate convergence.
- Autocorrelation is slightly high, but decays steadily.
- Densities are similar for first and second halves of the MCMC sample.

Example 2: `bayestest interval`

- We can perform interval testing with the postestimation command `bayestest interval`.
- It estimates the probability that a model parameter lies in a particular interval.
- For continuous parameters, the hypothesis is formulated in terms of intervals.
- We can perform point hypothesis testing only for parameters with discrete posterior distributions.
- `bayestest interval` estimates the posterior distribution for a null hypothesis about intervals for one or more parameters .
- `bayestest interval` reports the estimated posterior mean probability for  $H_0$ .

```
bayestest interval ( {y:x1} ,lower(.08) upper(.12)) ///
                   ( {y:x2} ,lower(-.12) upper(-.09))
```

## Example 2: bayestest interval

- We can, for example, perform separate tests for different parameters:

```
. bayestest interval (({y:x1},lower(.08) upper(.12)) ///
>                    ({y:x2},lower(-.12) upper(-.09))
Interval tests      MCMC sample size =    10,000
prob1 : .08 < {y:x1} < .12
prob2 : -.12 < {y:x2} < -.09
```

	Mean	Std. Dev.	MCSE
prob1	.4909	0.49994	.0199632
prob2	.1926	0.39436	.0145117

- If we draw  $\theta_1$  from the specified prior and we use the data to update the knowledge about  $\theta_1$ , then there is a 49% chance that  $\theta_1$  belongs to the interval (.08,.12).

- We can also perform a joint test:

```
. bayestest interval ((({y:x1},lower(.08) upper(.12)) ///
>                    ({y:x2},lower(-.12) upper(-.09)),joint)
Interval tests      MCMC sample size =    10,000
prob1 : .08 < {y:x1} < .12, -.12 < {y:x2} < -.09
```

	Mean	Std. Dev.	MCSE
prob1	.0885	0.28403	.0098171

## Example 2: bayestest interval

- We can, for example, perform separate tests for different parameters:

```

## Example 3: Change-point model

## Example 3: Change-point model

- Let's work now with an example where we write our model using a substitutable expression.
- We have average oil prices for January 1986 to December 2015:

- The series has a significant increase around 2005.
- We may consider fitting a change-point model.

## Example 3: Gibbs sampling

Change-point model specification with blocking

```

bayesmh oilprice = ({mu1}*sign(year<{cp})           ///
                    + {mu2}*sign(year>={cp})),      ///
                    likelihood(normal({var}))        ///
                    prior({mu1}, normal(0,50))      ///
                    prior({mu2}, normal(50,150))    ///
                    prior({cp}, uniform(tm(1986m1),2015m12)) ///

Summary

References

## Example 3: bayesgraph trace

- Use bayesgraph trace to look at the trace for all the parameters.

**. bayesgraph trace \_all,combine**

- The plots indicate that convergence seems to be achieved.

## Example 3: bayesgraph ac

- Use bayesgraph ac to look at the autocorrelation for all the parameters.

## . bayesgraph ac \_all,combine

- Autocorrelation quickly becomes negligible for all the parameters.

## Example 3: bayesgraph matrix

- Use `bayesgraph matrix` to look at pairwise correlation for the parameters.

## . bayesgraph matrix\_all

- The plots seem to indicate that there are no significant pairwise correlations among the parameters.

## Summing up

- **Bayesian analysis:** A statistical approach that can be used to answer questions about unknown parameters in terms of probability statements.
- It can be used when we have prior information on the distribution of the parameters involved in the model.
- Alternative approach or complementary approach to classic/frequentist approach?
